The map prepared by Mr. Rolfe is to be one of the big things of the Illinois show. It is 10 feet wide and 16 feet long, modeled in clay. A number of experts at the University of Illinois are just putting the finishing touches on it. The map will cost $15,000. Engineering corps were put in the field more than a year ago to collect data. Mr. Rolfe realized the need of taking advantage of all the data that had previously been gathered, and in doing this he saved great expense.

Some years ago a committee of the Western Society of Engineers reported that an appropriation of $20,000 a year for 56 years, or $1,120,000 in all, would be required to make an accurate topographical map of the State. Mr. Rolfe and his assistants used the data collected by the Mississippi River Commission, which included a line of levels from Cairo to Dunleith; a line of levels from Fulton to Chicago along the St. Paul Railroad, and a series of topographical charts of the Illinois share of the Mississippi and the low water slope of the Mississippi. From the lake survey he got a series of geodetic stations between Chicago and Olney. The Canal Commission furnished data of low water levels of the Illinois River. Topographic charts of the country between Chicago and Peoria were secured from the United States Geologic Survey and a line of levels from Olney to St. Louis and from Centralia to Cairo, with low water levels of the Ohio and Wabash rivers, were furnished by the Coast and Geodetic Survey.

These statistics were supplemented by data of the preliminary survey of the Hennepin Canal and profiles of every railway line in the State. The exact relations of the railroads at intersecting points were ascertained, and the profiles of the roads checked on each other, using those that had been corrected by United States data as master systems. To the outline so established, the details of the surface were added by traverses, with barometer and hand level, arranged to intersect railroads as often as possible, and practically to bring the observer within sight of every section of land in his district. Prominent points, either of elevation or depression, were visited and observations made upon them. Many cross checks and other means of correction were applied to overcome errors in atmospheric pressure, instrumental irregularities and errors of observation.

Finally, the results obtained were expressed in contour lines on the maps. Care was taken to make the maps more correct in their horizontal features than any heretofore published. The locations of towns and courses of streams were in most cases either verified or corrected.

This great map will show the precise location of every town and railway station in the State, the position of all the public buildings and State institutions and township and county boundaries.

Rules for Placing Exhibits.

Director-General Davis and Director of Works Burnham have agreed upon a set of rules for the government of exhibitors in the matter of installing exhibits. It is desired that the installation shall be artistic and harmonious throughout. Cheap arrangements will not be permitted, and designs must prove satisfactory to the Director of Works and the several chiefs of departments. The regulations, which are of interest to every intending exhibitor, are as follows:

Method of procedure when an exhibitor wishes approval of designs, location and style of foundations, sort and arrangement of lights, power, sewerage, water, gas, &c.:

1. Exhibitors shall submit full drawings, specifications and details to the chief of department in which the exhibit is to be installed, together with his address and office hours, and agree to hold himself ready during the following 48 hours to meet and further explain such drawings, specifications and details to those engineers whom it may be necessary to consult.

2. The chief of department shall thereupon be charged with obtaining approval from the Director of Works or his assistant of the drawings, specifications and details submitted so far as it shall be necessary to do so.

3. The chief of each department shall have a fixed hour before noon each day in which to see exhibitors, and the drawings and information necessary shall be sent to the Director of Works by or before 12 o'clock each day.

4. The Director of Works shall have a special secretary to attend solely to this work, who shall have special quarters at the Service Building in Room 18.

5. Such engineers and architects under the Director of Works as may be called on to pass upon matters for exhibitors pertaining to designs, construction, water, gas, mechanical and electrical engineering, &c., shall meet each week day at 1 o'clock p.m., in the office of said secretary, and shall pass upon all matters submitted in this behalf, and on the blanks provided for the purpose their findings in each case shall be recorded and at once signed by the Director of Works or his assistant and transmitted to the chief of the department whence it originated.

6. The chief of the department shall thereupon at once issue the permit to said exhibitor and he shall be allowed to proceed in accordance with its terms.

7. Exhibitors will furnish such duplicate plans, drawings or specifications as may be required by the Director of Works.

Stockholders are Paying Up Well.

Exposition stockholders have paid up well. In his report to the Board of Directors yesterday Auditor Ackerman showed that on 597,650 shares of stock of the value of $10 each $5,509,767 have been paid, leaving an unpaid residue of $466,733, or approximately 7.8 per cent. of the whole.

According to Treasurer Seeberger's monthly report, there is a balance in the treasury of $573,879. His report shows further that from the sale of souvenir coins $836,438 has been received, as well as premiums on the same amounting to $10,000. This applies to the coin secured by the Remington people. The total disbursements and receipts are set forth by Treasurer Seeberger as follows:

Balance received from temporary organization	$4,252.64
Received on current installments of stock subscriptions	5,423,496.20
Received from banks, interest on deposits to January 31	65,368.53
Received from City of Chicago account sale of bonds	5,003,726.06
Received for souvenir coins	836,438.00
Received for premium on souvenir coins	10,022.28
Amount of gate receipts at Jackson Park to February 8	193,093.26
Received account debenture bonds	3,617,500.00
Received account accrued interest on debenture bonds	16,866.61
Miscellaneous receipts from sundry sources	351,672.82
Received various stock subscriptions not yet classified	108.40
Received from various deposits on contracts, being amount on hand to credit of escrow account	79,000.00
Received from Dept. Public Comfort	1,875.00
Total	$15,603,419.80

DISBURSEMENTS.

Total disbursements on vouchers, as per daily report to auditor	$15,029,539.97
Total cash on hand	573,879.83
Total	$15,603,419.80

And Again the Boiler Suit.

The famous boiler contest has taken a new turn and now the advantage of the situation seems to rest with the Stirling Boiler Company. After the Master in Chancery, Winchester, filed a report in which he recommended an injunction restraining the fair management from allowing the Stirling Boiler Company to put its boilers in the space allotted to the Babcock & Wilcox Company, and also recommended that the court compel a specific performance of the contract between the Babcock Company and the World's Fair, the attorney for the latter asked on the 6th inst. to be allowed to remove the case from the local court to the United States Circuit Court. After a sharp contest between counsel the court granted the request. And now it is thought that a hearing can hardly be secured in time to do the Babcock & Wilcox Company any good, as the matter will have to take its turn and may not be called up until next year. In the meantime the Stirling boilers will be set in place and the exposition will have run its course.

Miscellaneous.

The Hon. E. H. Conger, United States Minister to the Republic of Brazil, writes Chief Walker Fearn of the Foreign Affairs Department, that the preparatory exhibition at Rio Janeiro of articles intended for the World's Fair was officially and successfully inaugurated in that city in January. The diplomatic corps were all present and were given posts of honor. The display was a marvelous one and surprised every one who witnessed it. The old National Museum was entirely cleared and the space was filled to overflowing. More than 500 packages were necessarily left unpacked at the docks, and many of the State exhibits will go direct to Chicago.

The Bethlehem Iron Company are erecting scaffolding preparatory to placing a duplicate in staff of the great hammer employed in the works of that company.

Weekly Prize Competitions.

$25.00.

FOR MORE than six months Weekly Prize Competitions ($10) have been an interesting and useful feature of the *Pharmaceutical Record*, a journal issued from this office and devoted to the interests of the drug trade. These weekly competitions have related to a variety of technical and business questions of interest to druggists, and have brought out a large amount of information of much service to the readers of that enterprising journal. In view of the success of this feature we have decided to announce a similar series of Weekly Prize Competitions on questions of interest to our readers, and invite a general participation on the part of the trade. As the object of these competitions is to obtain information which will be of practical service to our readers, and to discuss questions in which they are interested, we shall esteem it a special favor if any in the trade will suggest subjects for such competitions, which, if deemed suitable, we shall take pleasure in using.

In each competition there will be three prizes—a first prize of $12.50, a second prize of $7.50 and a third prize of $5. The prizes will be awarded for the answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. These competitions are open to every one, and it is hoped that there will be a general response from business men. Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers to the different questions will be favorably regarded as meeting the purpose for which these competitions are announced. We shall have the privilege of publishing any or all of the contributions received.

Prize Competition No. 12.

SUBJECT:

Arrangement of Pocket Cutlery.

This competition is intended to call out practical suggestions in regard to the way in which pocket cutlery is displayed, and touches such points as the following:

Whether in show or wall cases and on flat or inclined surfaces;

The kind and style of boxes;

Whether samples and stock are kept together or separate;

Manner of marking prices;

How damaged or broken lots are disposed of;

Suggestions in regard to assortment of qualities and styles, and as to how the sale of the goods may be increased and made profitable.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

Replies are to be received not later than March 11, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 12.

Our weekly Prize Competitions Nos. 1 and 2 are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a good deal of practical information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 3. Closing February 18.
Waste in the Store and How to Avoid It.

No. 4. Closing February 25.
Suggestions as to Improvements in Putting up Goods.

No. 5. Closing March 4.
A Method of Securing a Reliable and Prompt Delivery of Goods.

No. 12. Closing March 11.
Arrangement of Pocket Cutlery.

Another subject will be announced in our next issue.

Our readers are also reminded of the following Prize Competitions, announced on another page, in each of which four prizes, of $50, $25, $15 and $10, are awarded:

No. 6. Closing February 18.
How Retailers Can Best Advertise and Extend Their Business.

No. 7. Closing February 18.
Travelers' Yarns.

No. 8. Closing February 18.
How to Treat Clerks.

No. 9. Closing February 18.
Shop System of Keeping Track of Jobs.

No. 10. Closing February 18.
Business Maxims—At Least 10.

No. 11. Closing February 18.
How Small Retailers May Keep a Record of Prices.

The *Railway Age* tells the following story: "When a locomotive freezes to the track while taking water so that its steam will not move it, and remains fast for four hours until another engine can be got to bump it loose, the weather may be said to be extraordinarily cold. Yet this is what happened to the engine of a fast Illinois Central train at a lonely water tank in Illinois one morning last week. Next time the boys will see that they do not let the tank overflow so as to form a pool around the tender trucks when the mercury is a rail length or so below zero. But it is strange that with railways running well up toward the arctic regions in this country it should be left to a road in central Illinois to be the scene of such an unusual occurrence."

The Board of Public Works of Austin, Texas, is in the market for about 9000 tons of cast-iron water pipe.

COPPERSMITHING.

ART OF COPPERSMITHING.

XL.*

DOME COPPERS.

Dome coppers, as will be seen, Fig. 456, are made similar to open ones, the dome being substituted for the light course. Let us suppose we have a copper ready for a dome, and it is required to make a dome seat 3½ inches wide, with a riveting edge turned up 2 inches deep, and the dome a half sphere, made in four pieces. To obtain the pattern for this we proceed as follows: The diameter inside the turned up dome seat or riveting edge, A B, Fig. 457 will be 104.63 inches. Then $\frac{104.63}{2}$ = 52.31, and $\sqrt[2]{52.31^2 \times 2} = 73.98$ or is to say, 52.31 − 36.99 = 15.32, and $\overline{F\,B}^2 + \overline{D\,F}^2 = \overline{D\,B}^2$, or $\overline{36.99}^2 + \overline{15.32}^2 = \overline{40.30}^2$; that is, it equals the chord D B of half the arc C D B; but D G equals D B, and $\overline{D\,B}^2$ minus one-half of $\overline{D\,F}^2$

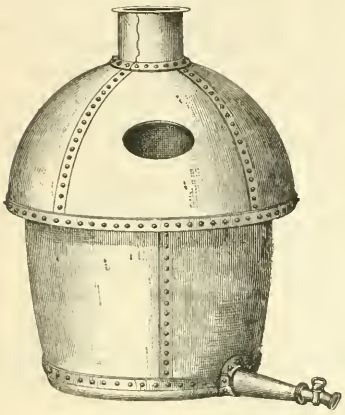

Fig. 456.—Dome Copper.

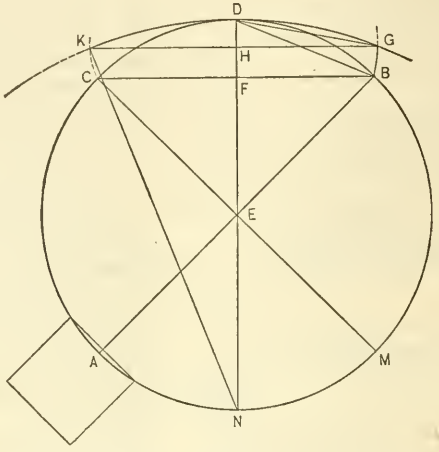

Fig. 457.—Method of Obtaining Pattern of Dome.

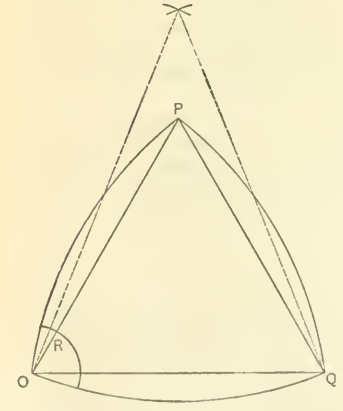

Fig. 458.—Pattern for Quarter of Dome.

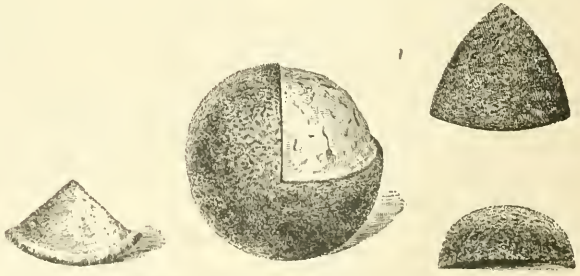

Fig. 459.—Illustration of an Orange.

dome and work it on to the copper. As I have said before, a dome may now be had in one piece, but were this not the case, then it must be made in pieces, and these must conform to the size of the sheets at hand. Now, let the size at the brim be as in the last example, namely: 97.63 inches in diameter, and the brim or C B; that is to say, it equals the side of the inscribed square of a circle, A B, whose diameter is 104.63 inches, or the diameter inside the riveting edge, represented by the circle D C A N B. Now, $\frac{73.98}{2}$ = 36.99, or one-half the chord C B of the arc C D B, or F B, and one-half the diameter D E − F E = D F; that (that is, $\overline{D\,H}^2$) equals $\overline{H\,G}^2$, or $\overline{D\,G}^2$ $\overline{D\,H}^2 = \overline{H\,G}^2$, which is $\overline{40.30}^2 - \overline{7.66}^2 = \overline{39.42}^2$. Then $\frac{\overline{H\,G}^2}{D\,H} + D\,H = D\,N \times 2$ or $\frac{\overline{39.42}^2}{7.66} + 7.66 = 209.25$, or the diam-

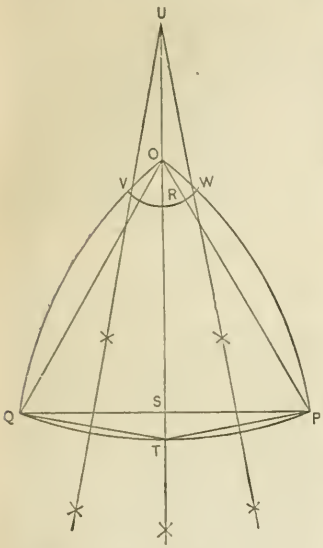
eter of a circle of which the curve of each side of the pattern is a part. Now construct a triangle on K G (that is, on O P, Fig. 458, which equals K G), and with D N or 104.62 or $\frac{209.25}{2}$ (that is, the diameter of the dome seat) as radius, describe the arcs about the triangle O P Q, as shown in Fig. 458. Then at one corner, O, of the pattern, with a radius, O R, equal to one-half the diameter of the crown pipe, mark out the hole for it, making the hole so that when complete it will be about 20 inches in diameter, which will then complete the pattern required of one of the four sections of the dome. Now, having the pattern and the four pieces cut out by it, bend an iron template to the curve of a radius of 48.81 inches, and take the sections to the hollowing tub and hollow them until they fit the template every way, after which planish them in a promiscuous way on a suitable head placed



Art of Coppersmithing.—Fig. 460.—Second Method of Obtaining Pattern.

in a solid block. Then punch them and place them in position in the seat, remembering to have the crown pipe also in position before the last quarter of the dome is put finally into its place. Next bolt them together in succession. The manhole may be prepared and fixed to the last quarter before placing, or it may be worked on after, at the discretion of the workman or employer. Put three or four temporary rivets in each seam of the dome and in the seat at each seam, and one or two between. We are now ready to work in the rivets, which may be done in a similar manner to that described and illustrated for an open copper with a light course.

I wish here to make a suggestion for the benefit of the boy who may have occasion to peruse these pages in the hope of finding the assistance he is in search of, because I think this is one of the most appropriate places which has suggested itself, where we can take a practical lesson from nature. Fig. 459 is the picture of an orange with the rind peeled off from three-fourths of the upper half of it, one-fourth being left on to illustrate a part of our lesson. Lying apart from the orange are the three-fourths of the rind which have been taken off. One piece is lying with the concave or flesh side of the skin upward and one with the concave side down and one lying perfectly flat. Now let us carefully consider these three pieces of rind in relation to the lesson under consideration. Let the upper half of the rind of this orange represent the dome of the copper in the next example, and let the dome be made in four pieces, as before. It will be readily seen that the four pieces of orange rind, after being removed from the orange, show in miniature: 1, the exact shape of the pattern; 2, the exact shape it should be when hollowed and planished, and 3, the position of the first piece when it is placed in the riveting edge on the copper brim. Now, if we conceive the edges for riveting to have been left on at two sides of the pattern, then the rivet holes of the seam would come down the line of division where the rind of the orange has been cut. With a little study this should be plainly understood. We will now proceed to find the shape and size of this pattern as suggested to us by the orange rind. Let the diameter C M of a spherical dome or an orange, Fig. 457, be 88 inches in the present example. Describe the circle A C B M to some easy scale that would represent a large-sized orange, say $\frac{1}{4}$ inch to a foot, and divide its circumference into four equal parts, A C, C B, B M and M A; then the diameter of the circle C M is $\frac{22}{16}$ inch, or $5\frac{1}{2}$ inches. Now draw the diameters A B and C M, and join C B; then the arc C D B represents the bend of either side of the section when hollowed to fit the surface of the orange. Draw D B, which represents the chord of half the arc C D B. Now divide D F in two equal parts at H, and through H draw K H G, parallel to C F B; then with D B as radius and D as center describe the arcs B G and C K, cutting K H G in K and G; then K G represents the true length of the side of a triangle O P, Fig. 460; that is, from point to point, when the section is lying flat the same as the orange rind in the picture, the line D B having remained the same as it was before the section was flattened and made a plane by being pressed down level. Here, then, we have the length K G of one side of a triangle lying within the pattern O P, Fig. 460, and we find by actual measurement that the line K G is full $4\frac{1}{2}$ inches, which, being multiplied by 16, is 66 inches (or more correctly, 66.1). Now bisect P Q in S, and through S draw O S and continue it to T, making S T equal to D H, Fig. 457, or one-half of D F; and draw the lines, or chords, T P and T Q; and bisect these chords perpendicularly, with lines meeting in U. Then from the point of intersection of these lines at U, with the distance U Q, U T, or U P (which is 5.5 inches, and this multiplied by 16 gives 88; the first, the diameter of the orange, and the second, that of the dome), describe the arcs O P, P Q, Q O. Now, with O R as radius, describe the arc W V for the crown pipe hole, and W P Q V is the pattern of one section of the dome as before, but without riveting edge, which must be left on the two sides W P and Q V.

There are very many useful lessons that may be learned in a similar way to that suggested here by the rind of an orange, if the student is apt and is of an inquiring turn of mind.

A member of the Dominion Parliament states that $20,000,000 have been expended on army rifles for that country, and that "gas pipe" would make more efficient weapons. A little while ago Germany, it will be remembered, was agitated by the announcement that a large percentage of the army rifles were defective, and Russia is now reported to have made a similar discovery. In regard to Germany and Russia the natural inference is that both governments welcome a pretext for preserving the peace.

Workmen to Study the Fair.

The Chicago *Herald* has undertaken a very enterprising scheme in connection with the World's Fair which is exciting much interest in labor circles in that city. The scheme as outlined in the *Herald* for the 5th inst. is as follows:

There are in Chicago many organized crafts. The fair will continue for 26 weeks. Each of the local labor unions will be invited by the *Herald* to choose from its membership a man deemed best qualified to act for it in studying processes, machinery, tools and materials peculiar to its interest, and the *Herald* will send him to the fair daily for one of these weeks, paying him $50 for his time and expenses, so that his family shall not lose by his personal and his representative distinction. It may be that more than 26 representative men will present themselves, in which case there will be weeks in which two or more experts will be given an opportunity to avail themselves of the proposition here made. It is the *Herald's* desire that at least one delegate for each week may be recommended by the unions, and if there are more than that number so much the better.

Each of the men thus selected will make as thorough an investigation as possible of the subject matter in his charge, and it will be expected of him that he will write for the *Sunday Herald* a report of his observations, to be published in its columns for the perusal not only of his own union and his fellow-craftsmen throughout the country and all over the world, but for the perusal also of the great general public, who will feel a keen interest in the observations of men thus chosen and thus equipped for so interesting and important a trust. Illustrations will be furnished for these reports to whatever degree may be found desirable.

The entire undertaking has been placed by the *Herald* in the hands of a committee composed of James J. Linehan, president of the Trade and Labor Assembly; John C. Harding, president of Typographical Union, No. 16, and J. B. Cogswell, president of the Carpenters' Union.

The project has been received with much enthusiasm, and we understand that some of the unions have already made their selection of the man whom they deem best qualified to represent their particular craft. It is one of the most practical methods yet devised for securing, not only a thorough and systematic study of everything in the wide domain of industrial and artistic progress which the fair shall present, but also the dissemination of the results of that study for the benefit of mankind generally. As a piece of journalistic enterprise it is most admirable and commendable. Although local in its character, being confined to representatives of Chicago trades, yet all classes of industry have reached such an advanced stage of development in that great manufacturing city that there need be no fear of any branch of industry being inadequately represented among the workmen chosen.

Here is Uncle Sam's account with the silver mines up to date:

	Ounces.	Cost.
Purchased under act of 1878	288,474,702	$308,195,497
Sherman act	129,926,795	127,257,410
Totals	418,401,497	$432,372,907
Present market value		351,457,257
Loss		$80,915,650

These figures are sufficiently eloquent.

The question of establishing a British labor bureau is under discussion. The Government desire to avoid both ministerial changes and the increase of legislative work. All that is actually known is that the general principle has been agreed to, and that, as soon as matters of detail have been arranged, the labor bureau will be established.

The Swedish inventor, Felix Starkenberg, whose wave motor and unique stern-wheel boat attracted attention, died in Brooklyn last week at the age of 47 years

THE LETTER BOX.

Pipes Freezing Below Frost.

From Z. S., *Haddonfield, N. J.*—Please inform me through the columns of *The Metal Worker* why it is that water pipes will freeze 2 feet below the frost. We are having quite a time in our town with pipes freezing and find that they are below the frost line 2 feet. These pipes are ¾-inch iron pipe leading from the main to the stop box at curbs. The main pipe in the middle of the street is 6 inches in diameter, made of kalameined sheet iron. One pipe I have in mind, leading from the main, was thawed out and froze up the following night, and I know it is below the frost line.

Note.—Not knowing why our correspondent should have had such a curious experience, we thought others in his part of the country might have had similar trouble, and wrote for information to another correspondent in the Southern part of New Jersey who we knew had investigated the frost matter to some considerable extent. In his answer he gives the depth of frost as found to exist beneath different sorts of streets and soils. His letter, which we print below, is of much interest, though it does not explain the trouble. We would request other correspondents to write us if they can solve the difficulty of frozen pipes as presented by "J. S."

"The following shows the kind of pavement, soil and depth of frost as determined by actual measurement from top of street to where the bar or pick would be dispensed with:

Kind of surface.	Kind of soil.	Depth of frost.
		Ft. In.
Unpaved street....	Gravel and sand....	3 4
Asphalt street.....	Gravel and sand.....	3 3
Stable yard.....	Ashes; made ground.	2 6
Cobblestone street.	Sand.....	4 0
Cobblestone street.	Gravel and sand.....	4 2
Asphalt street.....	Gravel and sand.....	4 2
Asphalt street.....	Gravel and sand.....	4 3

"The average depth on the lower part of the city of frost is 3 feet 10 inches. The great trouble that we have had with frozen supplies is that the city ferrules, which are drilled into the top of the mains, are some 6 inches nearer the surface than the main water pipe. If the ferrules were put on the side of the main there would be less frozen supplies in our city. I have never heard of water pipes freezing 2 feet below frost."

Painting Conductor Pipe.

From J. H. W., *Williamsport, Pa.*—In reply to the communication of "G. R. C.," Mansfield, Pa., in *The Metal Worker* of January 21, I wish to ask, why he wants to paint the conductors at all? It seems to me, the way tinners are going at it nowadays, that in the course of a few years they will have to be jacks of all trades in order to get a job. We shall be painters, stonecutters, carpenters, bricklayers, hodcarriers, and even dirt diggers. Now, fellow tradesmen, why not put a stop to all this kind of work? Surely, you only learn the trade of tinsmith; why, then, paint conductors inside? It is bad enough that we have to use paint at all. Hanging eaves, troughs and gutters ought to be painted, and that well, too, in order to preserve them. Why not let the painter do it, as it surely belongs to him and not to us tinners? Give the painter a chance to earn his wages. Why should we take his trade away from him? This can also be applied to the mechanics mentioned above. Let every mechanic have his own work to do and this will go far toward avoiding strikes, and will help wages. I wish I could see the tinner who first started to paint eave troughs and conductors. You ask what I would do with him? Now, if I was large enough, I would paint him up with red paint so that his mother-in-law would not know him from the ghost of Sitting Bull. I would like to hear from some of the tinners in regard to the above. Let them give their views on the subject.

Hot-Air Furnaces.

From S. S. T., *Chicago, Ill.*—In looking through the columns of your valuable paper of February 4 I noticed an article by "W. T." of Pennsylvania, of which kind I would be pleased to see more, for I candidly believe a freer interchange of opinions based upon actual experience both by practical furnace salesmen and practical mechanics would prove of infinite value to the trade at large in bringing furnace work to a much higher standard than it enjoys at present, especially in some localities. And what would help the dealer would reflect upon the furnace manufacturers as well, and would tend to aid the latter in their competition with the various other systems now being introduced. It is a well-established fact that a hot-air furnace of ample capacity, erected with the judgment and skill that a mechanic should incorporate in the work and a proper study of the laws of heating and ventilation, will give more complete satisfaction, viewing it from the standpoints of comfort and health, than any other system yet invented.

But these results cannot be obtained always unless all parties concerned will contribute a fair proportion of horse sense from the foundation up; yes, I might add from the time that the architect makes his first calculations, for it is to his judgment that the house owner must look and not to the suggestions that the furnace-heating engineer may make, not always with a view of cheapening or facilitating his share of the work, but with a view of aiding his apparatus to take advantage of every condition and substantiating the statements, which previous experiences have demonstrated he could honestly and conscientiously make. It has been the writer's experience to meet architects who were unalterably opposed to floor registers on the first floor, insisting on side walls only, and who were unwilling to listen to any reasonable argument in favor of floor registers, generally citing some building that had been warmed very satisfactorily by using side-wall registers, never stopping to consider the conditions existing whereby the former were preferable so far as results were concerned in the majority of cases, yet this same architect would make no provisions for using even the latter of suitable dimensions, but would confine the furnaceman to the limited space usually found in the ordinary partitions of a house, viz., 3½ x 14.

At the same time he would provide for the plumber, or in fact any other mechanic whose labor might enter into the construction of a modern house.

Again, it is of the utmost importance that the bricklayer in laying up the chimney exercise caution and judgment in his work. One frequently finds obstructions, caused by their carelessness, which require considerable time to locate, and proportionate expense to remove, while frequently the matter of suitable and proportionate area in square inches is a dead letter with them, they taking it for granted that a chimney supplying sufficient draft for an ordinary heating stove should prove ample for a large furnace. But aside from all this comes the difficulty of educating the house owner up to the importance of proper ventilation, especially when some unscrupulous dealer whose only qualifications are cheapness stands ready to do the work far below what an honest and conscientious dealer would do it for.

It was the writer's experience during the past year to be brought in contact with a party who was on most topics more than ordinarily intelligent, but whose ideas were somewhat limited regarding ventilation. It was indeed hard to convince him that a furnace would work better with the registers located on the inside of a room at a distance averaging 7 feet from furnace with suitable ventilation from the cold side than with the registers located on the outside of rooms at a distance of 20 feet from furnace and no ventilation. He, however, finally agreed to try the experiment, as he termed it, and during the recent cold spell a visit to his house showed that with an ordinary fire in the furnace and check drafts in operation, the temperature in all lower rooms averaged 74° F., while the upper rooms indicated an average of 72° F., while the quality of air seemed simply perfect. In this case the price received warranted the performing of a thoroughly first-class job.

In conclusion let me add that I hold that whatever is worth doing at all is worth doing well, and every man who has a certain piece of work to perform should take pride in doing it in a manner that will reflect credit upon himself as well as upon his employer. While it requires more skill to do a nice piece of furnace work than it does to put up a lot of conductor, yet the nature of the former fully warrants exercising the extra care. I sincerely hope to see a more thorough discussion of this really important topic on lines that will prove comprehensive and instructive from the apprentice to the experienced journeyman.

Trouble with a Gas Range.

From G. R., *Mansfield, Pa.*—For the information of readers of *The Metal Worker*, I would state that the gas stove, which I wrote you about in the letter published in *The Metal Worker* of January 28, has a flue connection of 4-inch pipe.

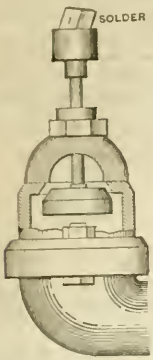
Note.—If the range is connected in this way with the chimney and all the products of combustion are carried off, we fail to see why there should be the condensation on the walls of the room complained of. If any reader can send an explanation of this trouble we shall be glad to hear from him.

Preserving Tin Roofs.

From C. L. F., *Clay City, Ill.*—I would like to ask "E. F. B.," Greenville, Pa., whose letter appears in *The Metal Worker* of January 28, to tell me what good the sand will do on the last coat of paint on a tin roof.

Trouble with a Hydraulic Ram.

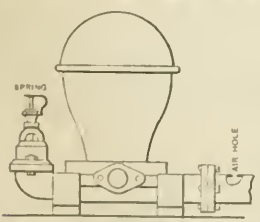
From A. J. L., *Glenville, Ohio.*—In *The Metal Worker* of January 21 I notice that "C. L.," New Haven, Conn., complains of trouble with a ram. Some years ago I had just such trouble with a ram that had been in use about 30 years. The brass outside, or pulsating valve, was very much worn and would keep stopping. I reasoned, that the valve being lighter than it



Trouble with a Hydraulic Ram.—Remedy Suggested by A. J. L.

originally was, was not heavy enough to fall when it was relieved by the air chamber valve. So with that idea I fastened a reducing coupling on the end of the brass stem and inside the coupling put a piece of solder, as shown in accompanying sketch. When I left it appeared to be working all right, and from inquiries I found that it continued to operate satisfactorily. One day I was near the ram and looked to see how it was, and found that the 1-inch piece cut off of the bar of solder was tossed into a piece of metal as round as a bullet from being continually thrown around within the coupling. This was some years ago, but the ram is still running with a piece of solder in the coupling and has given no trouble of late years.

From G. F. SCHAFFER, *Washington, D. C.*—In answer to the inquiry of "C. L.," New Haven, Conn., I would say (although his description is very meager) that he



Remedy Suggested by G. F. Schaffer.

had better put a spring on top of the valve so that when the valve is knocked up by the water in the drive pipe, as in diagram herewith, it just barely touches the spring, which always pushes the valve down. By placing the finger on the spring when the valve is in motion it should just be felt to touch. The air hole must be near the ram so it will supply the air chamber, otherwise the ram will work with a ruinous concussion. Perhaps the ram may be too large for the supply of water on hand.

From P. X., *Montpelier, Vt.*—Tell "C. L.," New Haven, Conn., whose letter appears in *The Metal Worker* of January 21, to reduce the fall of water to the ram or add weight to the impetus valve and he will overcome the trouble he complains of.

Leaking Cans.

From G. A. K., *Akron, Pa.*—I have a contract to put up a farmer's creamer, the tanks of which are lined with galvanized sheet iron and the cans made of XX bright tin, some being of copper. They are filled with fresh water morning and evening through pipes emptying in the bottom of the tank and discharging from the top. Some of those made of copper give me trouble, leaking in a short time, the water acting so hard on the solder that it actually eats it out of the joints. Inclosed find some of the solder, half-and-half, I scraped off one of the cans that had been in the water 13 weeks. Now, what is the cause and what is the remedy? The construction is such that it is impossible to solder them with hard solder. Do you think block tin would last?

Note.—It is difficult, if not impossible, to state to just what particular action the effect produced on the half-and-half solder is due. This is partly owing to a lack of more definite information as to how these copper cans are soldered and whether on the outside or on the inside. Basing our remarks on the data furnished, the primary agent inducing the action of disintegration of the half-and-half solder may possibly be something in the water itself. We are, however, rather inclined to attribute the effect to lactic acid from the milk, but in either case block tin would likely prove more durable.

Stamping Machine for Shop Use.

From J. M. D., *New York.*—Has there been published in *The Metal Worker* a description of stamping machine suitable for shop use, one that an ordinary mechanic could make himself? If so, please republish the article, giving description of machine.

Answer.—The following cuts and description of machine to be used for raising curved moldings appeared in *The Metal Worker*, and may fulfill our correspondent's requirements. In Fig. 1 is shown the side elevation of machine. A is a heavy block of wood that serves to hold the block of cast iron B, which is provided with set screws to hold in the block of wood C, to which the dies or forms are bolted. D is a similar block of iron, only it should not be as heavy as B. B and D are fastened to the wood work by bolts that go through the flanges. To have the machine work properly, the wooden block A should go into the ground or be made very solid, so there will be no rebound. When very large work is to be done, the iron D and the mold may not be heavy enough; then a lead cake or piece of iron can be fastened on to the beam above D, so as to get as heavy a blow as may be required. The beam E is secured to the holder K by means of two bolts. The plank sides F should be quite wide and made as firm as can be so the beam will

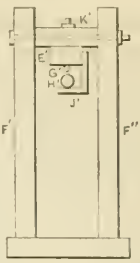


Fig. 2.—End Elevation, Showing Swivel.

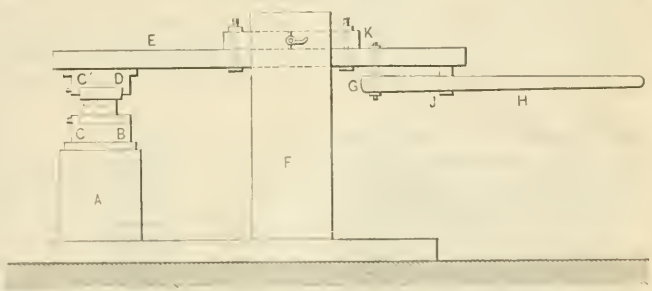
not "wobble," or the dies will not come together true. The swivel joint G is to allow the handle H to be withdrawn from the holder J. When working the machine it would be inconvenient to let go of the handle H, so as to allow the beam to fall, but by having the handle swiveled to the beam, and on the rest or holder J, the beam can be raised up as far as required, and when the handle is moved from the rest the beam drops with a sharp blow. The higher the beam is raised the heavier the blow will be. To have the machine arranged properly, so the dies could be adjusted, it would be well to have slots in the beam E so it could be moved forward and back along K, being secured in the desired position by means of the two bolts. Slots should be cut in the two side planks so the beam could be be raised or lowered at will, being secured by the bolt passing through K. In Fig. 2 is shown the partial end elevation of machine. F F represent the side planks through which the bolt passes to secure the beam holder K. The handle H is fastened to the beam E by the swivel G. When the beam is raised by means of the handle the handle is thrown to the left, thus passing beyond the holder J. The beam is then at liberty to fall and strike the required blow.



Stamping Machine for Shop Use.—Fig. 1.—Side Elevation of Machine.

The street canals in Venice are frozen over, rendering gondoliers useless, the first time in a century.

PLUMBING AND GAS FITTING.

The Milwaukee Convention.

Under date of January 31 Peter J. Somers, mayor of Milwaukee, has sent the following cordial letter to President Jeremiah Sheehan of the National Association of Master Plumbers:

It has come to my knowledge that it is the intention of the National Association of Master Plumbers to hold their eleventh annual convention in Milwaukee next June. This is more than pleasing news to our people, because it will be a pleasure for them to contribute to the comfort of the members of the association upon that occasion, and we feel that this city is abundantly able to accommodate this gathering of representative business men of the country. Milwaukee is fast becoming a convention city. Its location upon Lake Michigan is indeed most charming; this is most apparent in your convention month. Our hotel facilities are of the very best. The population of our city is about 250,000, and we will all feel honored by your visit. I am sure that the news of your coming to Milwaukee will be hailed with delight by all the plumbers of the city, who, by the way, are among the most enterprising, genial and prosperous of our fellow citizens; they will look after the interests of the convention with solicitnous care and will leave no want unprovided for. We promise you a pleasant time and a hearty welcome.

Sewer Gas and Trap Water Seal.

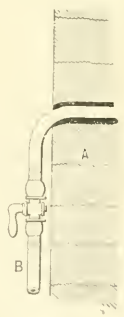
From F. P. G., *Cincinnati, O.*—In the answer to the communication in relation to the "Passage of Sewer Gas through Traps," which appeared in the issue of *The Metal Worker* of February 4, you admit that the water seal of a trap is no barrier to the entrance of sewer gas into a house unless the water is constantly renewed. What, then, is the advantage of a trap if, as a matter of fact, the gas can force its way through the seal, and why is it impressed so upon the plumber that all his work must be gas proof?

Answer—The protection which the water seal affords is from disease germs, which cannot pass through the water, but which would have free access if the seal is broken. A well known English authority, Dr. Fergus, stated some years ago the result of experiments made, demonstrating the ability of gas to so impregnate the water seal as to give off on the house side the gas entering from the sewer side. But the germs of disease are retained in the water and are not supposed to enter the building unless there is a free passage of the sewer air, which can only occur through the trap being unsealed. If, therefore, on the one hand the sewer air in its passage through the water in a vented trap is deprived of its more dangerous characteristics, and on the other hand the unvented or improperly set trap admits the sewer air as it comes from the sewer laden with disease germs, the importance of the good plumbing work, as represented by the former, needs not to be impressed upon the plumber. In one case we have the offensive odors alone, in the other we have both the offensive odors and the disease germs. In connection with this subject an experiment made some years ago by Professor Doremus may be interesting, and we give it for our correspondent's benefit. To each end of a block of brown sandstone 12 inches long by 4¾ inches thick the professor attached an iron plate and tube. The sides and other parts of the block except where these plates and tubes were inserted were covered by many layers of varnish to render the stone impervious to gases. A flexible tube was next fastened to a gas jet and connected with one end of the sandstone block and the gas was turned on. After waiting for a few minutes he applied a lighted match to the tube at the other end of the block and a small flame was kindled, showing that the gas had passed through the solid stone. There is no precise analogy between the sandstone block and the water in the trap, but it serves to illustrate the power of gas to permeate substances. It must not be inferred that the sewer air flows through the water seal as it would through an open pipe, but merely that the water seal is not always a perfect barrier to the gas, though it is to the germs.

Thawing Frozen Street Mains.

From J. R., *Portland, Maine.*—Can *The Metal Worker* give any points as to the practice adopted by New York plumbers in thawing out frozen street mains? We all have methods of our own, but it is well now and then to exchange views with others.

Answer.—The thawing out of street mains in New York City is effected in most part through the agency of live steam, while in many instances hot water



Thawing Frozen Street Mains.—Fig. 1.—*Water Main at Cellar Wall.*

is used—the preference, however, being given to the former. The method of operation is as follows: The main pipe is cut where it enters the front wall in a cellar and on the street or outer side of the stop cock. The end of the frozen section of the pipe is then attached to one of the openings in the cross branch of a galvanized-iron T, while the arm of the T is attached to the house section of the water pipe by means of soldering nipples. The plumber next gets up steam in a machine resembling a diminutive kitchen boiler, furnished with the necessary appliances to regulate the amount of pressure needed. This machine is set on a furnace and partly filled with water, sufficient room being left for the steam,

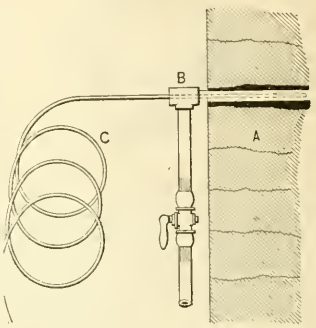


Fig. 2.—*Method of Thawing.*

which is injected through a coil of ¼-inch tubing inserted in the open end of the T into the frozen pipe. According as the ice is melted the tube is pushed in further, until the entire length of pipe is penetrated and cleared of the obstruction. The tube is then withdrawn and the opening in the T through which it was operated is plugged, the T being allowed to remain for future use if an emergency should arise. Some of the plumbers are content to work with hot water instead of steam and are satisfied with the results, although it must be apparent that live steam under adequate pressure must operate much more rapidly on the ice in the pipes than water. It should be borne in mind that in plumbing work the plumber must be able to meet special cases by modifications of well recognized plans to suit circumstances. It is not alone necessary to understand the plumbing business, but the successful plumber must be a man of resonrce when the emergency calls for it.

In the accompanying illustration Fig. 1 represents the water main where it enters the front wall of cellar. A represents the front wall and B the pipe. Fig. 2 represents the pipe cut with the galvanized T inserted, the cutting of the pipe and the attachment of the T thereto being effected at the point B. The coil of tubing is represented by C.

The Clow Patent Lead Pipe Connection.

James B. Clow & Son, Lake and Franklin streets, Chicago, are manufacturing this article, which has much to recommend it in its simplicity, effectiveness,

The Clow Patent Lead-Pipe Connection.—Fig. 1.—General View of Connection.

cheapness and saving of time. It is intended to be used in place of a solder joint in connecting lead and iron pipe.

Fig. 1 is an illustration of the connection, while Fig. 2 is a sectional view showing the form of its interior. In using this connection, it is first slipped over the end of the lead pipe. A steel expander, which

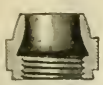

Fig. 2.—Sectional View of Connection.

is merely a tapered steel bar, is then inserted to spread the pipe and press it into the chamber in the connection. The iron pipe is then screwed in at the other end of the connection, is brought up tightly in place and helps to hold the lead pipe fast, as will be seen in Fig. 3, which shows a piece of lead pipe inserted between a corporation cock and a round way stop. A portion of one of the connections is cut away so as to show how the several parts come together.

The manufacturers guarantee this joint to be stronger and more durable than the regular solder joint and much cheaper. It is made in four sizes—½, ⅝, ¾ and 1 inch.

Electricity and Water Pipes.

Not long ago we referred to trouble that has been experienced abroad by the corrosion of lead pipe, due, it was assumed, to the nearness of electrical cables. The second instance of the kind we noted was in this country, but no systematic investigation had been made, and it was difficult to determine exactly in what way the corrosion was promoted by the electrical current in a neighboring wire. Quite recently a correspondent of *Fire and Water*, writing from Memphis, Tenn., calls attention to the same thing. We quote from his letter below:

"About 12 or 15 months ago our street railway system was changed from mule power to that of electricity, since which time we are having so many leaks in service pipes under the electric railway track that I am led to believe that the electricity has something to do with these numerous leaks, though the wires under the tracks do not come in contact with the pipes. We use iron and lead pipes for service, galvanized iron principally, and many of these give out inside of one year, and some have given out inside of three months, and in every instance under the railway track, which fact leads me to believe that the electricity is responsible for the trouble, though I am not able to explain why."

It would seem that with the greater application of electricity to motor and lighting purposes this trouble of corroded water pipes is likely to increase. It would be well, therefore, for the electrical companies or water companies to discover the exact cause of the trouble with a view to applying a remedy.

Testing Iron Pipe and Lead Work with Water.

From A. P. V., *Cincinnati, Ohio.*—I went security some time ago for a plumber to whom was awarded the contract for the plumbing of a private residence on that delusive system, the "lowest bid." The man had the reputation of being a good workman, and I provided all the material, which was of the best character. Before the job was completed he left for parts unknown, and I have to see to it that the work is done in accordance with contract. I find that one of the conditions is that the whole of the iron pipe and lead work is to be tested with water, and as most of the fixtures are in place, it appears to me difficult, if not impossible. How can it be done, and what benefit is to come from testing lead pipe? In the absence of proper plugs, what is the best way to sustain the pressure of the whole system filled with water?

Answer.—Presuming that the iron pipe is of the grade of "extra heavy" and the joints well made there should be no difficulty in applying the water test so far as the lines are concerned. When it comes to testing the lead work the only course open is to remove such of the fixtures as are in position, cap all the lead pipe openings and fill up. First of all, of course, the house drain must be securely plugged at the front wall trap—if there is one—and that can be easily done. A prominent New York plumber who tests the entire iron pipe in a building at once is in the habit of calking in a circular piece of 6-pound lead, when making the joint on the house drain nearest the running trap on the inlet side. He then fills up his pipes, the lead sheet answering all the purpose of a plug. When the test is satisfactory, putting his hand through the trap he cuts out the lead and leaves the pipe clear. There is both advantage in and frequently necessity for testing the lead work in buildings. It is but little use to make iron pipe joints secure if the ferrule joints on the application of a test are defective, and no piece of house plumbing can be guaranteed as safe if the joints connecting the lead and iron pipe are not subjected to either a water or air test. Any good plumber, knowing his business and having a level head, can easily get our correspondent out of his difficulty.

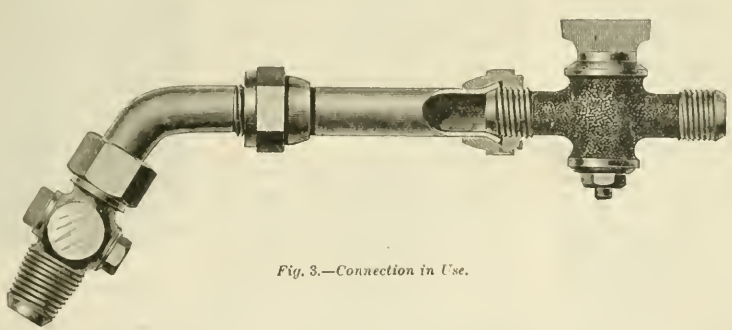

Fig. 3.—Connection in Use.

Ball of the St. Louis Master Plumbers.

The Liederkranz Hall, St. Louis, Mo., was crowded by a merry party Wednesday evening, February 8, on the occasion of the annual ball of the Mound City master plumbers.

Between the hours of eight and ten 100 carriages rolled up to the entrance of this popular south-side hall, with twice as many couples, intent on taking part in the festivities.

The hall was handsomely decorated, the music charming and the tables were lavishly spread with epicurean dishes that would satisfy the most critical. At the completion of the last course, the ladies were presented with handsome souvenir spoons with gold bowls, and the initials "M. P. A." engraved therein. All the arrangements were made and executed in such a manner as to reflect credit upon the committee in charge.

During the evening ex-Secretary Jno. P. Kelleher, who has so efficiently performed the duties of his office, was presented with a gold watch. The presentation was so complete a surprise to Mr. Kelleher that he found difficulty in finding words to express his appreciation of the beautiful remembrance.

It was in the small hours of the morning before the dancers departed for their homes, all voting it a grand success and one to be long remembered.

TRAPS AND VENTS.

The Toronto Steel Clad Bath & Metal Company, Limited, Toronto, Canada, wish to contradict the statement that they have purchased the United States and Canadian patents of the Peerless water heater. At present they are merely agents for them in Canada.

The Folding Bath Tub Company, Marshall, Mich., issue a very pretty catalogue illustrating and describing the combination folding bathtubs and sanitary bath chairs of their manufacture. The publication, of oblong shape, is printed on tinted paper and contains a full account of the goods mentioned. The catalogue is written very pleasantly and gives a

good deal more than the mere technical details of the construction of the various apparatus. The illustrations present the appearance of the tubs and chairs very faithfully.

JOHN H. MESSIER, Worcester, Mass., is the patentee of a water heater designed especially for use in barber shops. The heating apparatus consists of a horizontal boiler having a suitable burner underneath, provided with a special system of pipes connected with a cold-water supply, the heater being a small separate apparatus underneath the basin.

A SAFETY LOCK for gas cocks has been patented by Frank Lawrence, San Francisco, Cal. The invention relates to the class of safety devices for this purpose in which a spring-controlled lever is connected with the key and has the upper end adapted to engage the notches in the lower flange of the valve seat. The general result is effected of permitting the easy operation of the key, and its positive locking when the valve is shut off on either side.

CRANE COMPANY, 10 North Jefferson street, Chicago, have just issued a 26-page catalogue of water works supplies. Illustrations and descriptions are given of fire hydrants, check valves, solid wedge straightway valves, double disk straightway valves, valves for service pipes, bibb cocks, compression bibbs, rough stops, checks and wastes, corporation stop cocks, crows, water-pressure regulators, Mueller's tapping machine, valve boxes and flange fittings. An introductory note to this catalogue states that during the past season the company have furnished 100 cities and towns with hydrants and valves. They now claim to manufacture the greatest variety of water works supplies in America, always carrying a large line.

SEALED PROPOSALS will be received by W. W. Johnson, Custodian U. S. Post office, Baltimore, Md., until 2 o'clock p.m., February 23, for furnishing and putting in place complete water closets in the U. S. Post Office, Court House, &c., building at Baltimore, Md.

THE TRIMONT MFG. COMPANY, Roxbury, Mass., are much pleased with the success their Trimo A Plumbers' Wrench has met with in the past three or four years at the hands of dealers and users, among the latter being the New York Steam Heating Company, who, we are informed, find it especially adapted to their requirements. Some of the features of this tool are referred to by the makers as follows: That it is drop-forged from bar steel and all parts interchangeable. Grips the pipe firmly without lost motion, and will not lock upon the pipe, but in reversing releases its hold instantly. They allude to the demand as increasing both for domestic and foreign consumption. The Trimo Chain Pipe and Basin Wrenches are also manufactured by this company.

A RECENT ADVERTISEMENT in a local Ansonia paper contains some entertaining verses referring to the plumber, and below is a note in which the song is "disrespectfully dedicated to a friend who resides in Ansonia who unscrews his water pipes and takes them to bed at night to prevent them from freezing, and thereby beats the legitimate plumber out of a job." The signature of the advertisement is 278 Main street, Ansonia, Conn., where, we believe, a Mr. Reynolds lives.

VANDERMAN'S Plumber's Estimate and List Book, published by the Vanderman Plumbing & Heating Company, Willimantic, Conn., is a volume of blanks containing over 200 pages. The trade are more or less familiar with the style of these estimate blanks. The form for each job covers two pages, and includes a printed list of all the material likely to be used in plumbing work. These are arranged on separate lines, with columns opposite for dollars and cents in which is entered the total amount for the various articles. There are also a number of miscellaneous items of expense given at the bottom of the second page. A feature of the present edition of the work is a ledger index in the front page, by which the jobs can be quickly referred to and also a number of price-lists on standard goods such as lead pipe, iron fittings, brass fittings, compression brass work, soil pipe, boilers, traps, &c.

GEO. A. YUILLE, formerly president of the Chicago Economic Gas Company, will take charge of maintenance of the Clow Sanitary Company at the World's Fair. There will be 3000 closets, 2000 urinals and 1500 lavatories in the buildings and about the grounds. Of these one-third will be free, and for the other two-thirds an admission of 5 cents will be charged. The company will employ over 400 people in connection with the above.

J. J. WADE & SON, plumbers and sanitary engineers, 298 Dearborn street, Chicago, are doing the plumbing in a number of the largest and handsomest buildings in the city, among which are the following: Old Colony building, 17 stories, Dearborn and Van Buren streets; Boyce building, 15 stories, Dearborn street; Kedzie building, 10 stories, Randolph street; Watson building, 10 stories, Franklin street; also the famous Newberry Library and other buildings of less note. These buildings are being fitted with Wade's patent sewerage system, and, in fact, Wade & Son are constantly introducing this advanced system in buildings in Chicago and surrounding country.

Maddock & Sons' New Pottery, Trenton, N. J.

Work has been resumed at the renovated pottery establishment of Thomas Maddock & Sons, at Trenton, N. J., which, it is said, can now produce 60 per cent. of all the sanitary ware manufactured in the United States. This pottery was the scene of two disastrous fires during last year which demolished the entire plant. It has now been rebuilt on an enlarged and improved scale and is said to be one of the finest examples of its class in existence.

The building is in the shape of a hollow rectangle, inclosing the kilns. It is of brick faced with white trimmings and stands five stories high. Some idea of the massive character of the work can be secured from the following figures: Structural iron work, 1,000,000 pounds; bricks used, 2,400,000; entire frontage of the three main sides, 548 lineal feet; floor space, 115,422 square feet; galvanized iron used in roofing, 35,000 square feet; galvanized iron used in ceilings, 85,000 square feet. Nearly 700 barrels of cement were used in the cellar floor.

The five kilns are of Lawson's patent, large down-draft pattern. Special attention is stated to have been given to securing immunity from fire. To this end the roof, ceilings and doors have all been made of corrugated iron, a portion of the flooring and shelves being the only wood in the buildings. In the portion used for storage of the valuable models and molds the floors are cemented.

The fittings and equipments of the building, in machinery and otherwise, are of the best and most approved nature. A complete electric plant has been installed, operating 300 lights.

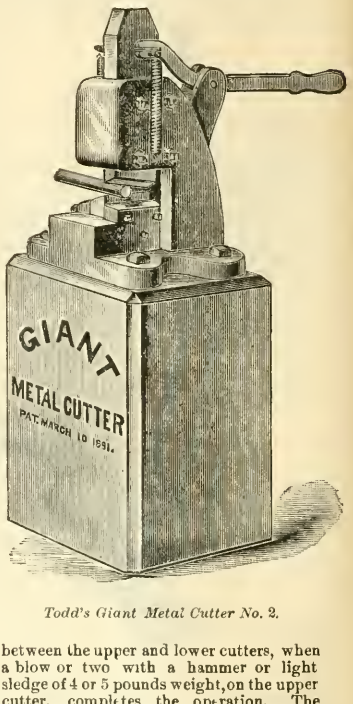
The whole plant will be devoted exclusively to the manufacture of sanitary ware, 350 hands being in employment. Messrs. Maddock will continue the production of general ware at the old Trenton China Works in that city.

The formal act of raising the American flag on the Inman steamers "Paris" and "New York" will take place on Washington's Birthday, and it is said that President Harrison and his cabinet will participate in the ceremony. James A. Wright, Jr., vice president of the International Steamship Company, is quoted as saying that the company propose to have built at least six steamships in the United States equal to those just named.

Todd's Giant Metal Cutter No. 2.

Henry B. Todd, Meriden, Conn., is manufacturing the Giant Metal Cutter No. 2, as herewith illustrated. This machine is an improvement on Giant Metal Cutter No. 1, previously illustrated in *The Metal Worker*, being designed to cut bar iron and all softer metals, from the thickness of sheet tin to rods 1 inch in diameter. The machine consists of a casting of best steel, having a bottom cutter held rigidly in place by set crews, as shown in the engraving, with a top cutter working up and down through the casting.

The top cutter is raised by the hand lever and the piece to be cut is inserted



Todd's Giant Metal Cutter No. 2.

between the upper and lower cutters, when a blow or two with a hammer or light sledge of 4 or 5 pounds weight, on the upper cutter, completes the operation. The spiral springs are intended to hold in place the piece of metal to be cut when it is so large that repeated blows are necessary. Giant Metal Cutter No. 2 cuts shear fashion. The parts are made in duplicate, so that extra parts can be furnished at any time to replace those worn or broken. The size of the cutter is $3\frac{1}{2}$ x $\frac{3}{8}$ in., and shipping weight of machine about 135 pounds.

W. K. Vanderbilt's steam yacht "Valiant," building in England, will have two sets of triple-expansion engines to drive her twin screws of bronze. Her indicated horse-power will be 5000, this great power being necessary to drive her 18 knots when loaded, 17 being her guaranteed speed at sea with moderate forced draft. Her length between perpendiculars is 310 feet.

The forthcoming sugar crop of Brazil is estimated by United State Consul Stevens at near 225,000 tons. The planting for the crop of 1893-4 is the largest on record.

Liquid Air.

Professor Dewar, a distinguished English scientist, in a recent lecture delivered before the Royal Institution of London, gave some interesting results of investigations made by him into the properties of liquid oxygen. This liquid was until quite recently a curiosity produced only in minute quantities, too small and too evanescent to admit of any exact and systematic examination of its properties. As liquid oxygen boils at 182° below zero, it is, in an ordinary temperature, always in a violent state of ebullition, which means rapid dissipation, and which presents, from its agitated condition, a fatal bar to any extended experiments as to its qualities. This difficulty has been overcome by Professor Dewar in the discovery that by surrounding a vessel containing the liquid with a very high vacuum the influx of heat from the outside would be reduced to one-seventh. The result is liquid oxygen at a temperature below its boiling point, tranquilly and slowly evaporating as water evaporates at moderate temperature. Mr. Dewar is able to produce the liquid by the pint, and demonstrated his discovery practically by exhibiting a bulb containing a quantity of liquid oxygen, protected by the means above mentioned, the contents of which only evaporated one-fifth during the progress of the lecture, notwithstanding the heat of the room. The phenomena shown point to the conclusion that there is practically no radiation across an absolute vacuum. It was also demonstrated that atmospheric air can be condensed into a liquid at ordinary pressure by the cold of liquid oxygen boiling under the air pump. Liquid air thus obtained was shown in quantity. Many other interesting experiments were carried out, suggesting new fields of scientific research in this line, and even pointing to a near solution of the problem of liquefying hydrogen.

Authority and Trust.

A great deal has been said about the risk in practical mechanical work of a blind trust in authority, and about the true mechanic who accepts no statement of fact that he cannot himself verify; but, as a matter of fact, in mechanical operations, whether in the humble shop in a country town, or in the magnificently equipped establishment such as may be found in favorable localities, where capital can and does command the highest engineering skill, wherein accomplished draftsman are constantly employed, and every facility for accurate work is supplied, a very small proportion of the fundamental facts that in daily practice are made the basis of this or that mode of procedure have been verified by any engineer, draftsman or workman who ever set foot on the premises. These facts are taken on trust as established; that is to say, the statements of fact as made by accepted authorities are accepted with confidence as contained in books of reference; and this being the only practicable course that can be pursued is the wise course. Consider how much work of a paying kind could be done, if all the tabulated statements of tensile strength of materials, of the transverse strength of beams under variously distributed loads, of weight of materials, of elasticity, of coefficients of friction, of the properties of steam, of specific heats and specific gravities, of the heat units generated by combustion of equal weights of different fuels, &c., in a list that would require a large volume even to name them, had each, before they could be accepted, to be personally verified by experiment or by a mathematical demonstration. Evidently the longest life would be far too short to perform the labor that these tabulated statements represent—a labor that has absorbed the energies of thousands of lives, and has exhausted the powers of thousands of the brightest intellects the world ever produced.

Established Authority.

Since, then, we must live by faith, no less in practical life than in religious belief, we must seek to place our faith where it will not bring us to grief and disappointment. In cases where we doubt a statement made by an authority we must verify, or take the risk of failure, with the equally possible chance of success. Most people are obliged to take the chances in such exigencies, because, if they have the educational qualifications for the needed research, they have not the time, or if they have the time they have not the qualifications. Perhaps it would more nearly hit the exact truth to say that most men in the mechanical trades have neither the time nor the qualifications, to say nothing of the apparatus needed for accurate experimental work. They must, whether they like it or not, sink or swim by the aid of such records of results as are obtainable from books and journals printed for the benefit of their respective trades. The authors of these publications may be called established authorities. Many of them speak wisely and accurately, and their teaching will be of inestimable value to future generations, as it has been to our fathers before us. These benefactors of the human race have erected permanent guide boards that stand as monuments to perpetuate their memory long after they have passed from the stage of life.

The Selection of Authorities.

As there are many books published so full of inaccuracies that they are like dangerous tools, treacherous things to have around the shop, it is very desirable to avoid them. Books of this kind do not long go unchallenged, and the best men in any trade are always competent to name books that are free from important errors and well fitted for the uses of their calling. It is safe to say that no misstatement of important facts long remains undetected in this age of sharp scrutiny, active inquiry and rapid spread of information. Nearly every trade now has publications more or less exclusively devoted to its interests. These papers make it a point to scrutinize and carefully review books purporting to be written expressly for their respective trades. Such books, new or old, are compelled to run the gauntlet of criticism, both as to matter and method, and are thus soon exposed in their weakness or confirmed in their value, according as they are unreliable or of authoritative character. It is not the least service rendered to industry by valuable trade newspapers that their correspondence and editorial columns afford an open arena for the challenge and discussion of all doubtful or disputed questions of fact of interest to their readers; and for this reason, if for no other, no progressive mechanic can afford to dispense with a good trade publication pertaining to his special calling.

Drainage and Ventilation of Stables.

The sanitary condition of stables is a matter which has not received anything approaching the attention which it deserves. The effects of an intelligent consideration of this question, followed by the necessary action for bringing about improvement, have been strikingly instanced by Edward Tidman of London in a paper on "Sanitary Ventilation" recently read by him before the Surveyors' Institution of that city. The case quoted is one of a cavalry barracks, where the death rate of the horses was 180 to 197 per 1000 per annum. The stables were rebuilt on designs in which provision was made for efficient drainage and ventilation, and during the following ten years the death rate fell to 28.50 per 1000. Mr. Tidman says that 75 per cent. of town stables in England are in such an unsanitary state as to be dangerous to man and animals, and to this cause is attributed the prevalence of glanders and farcy and other diseases among the horses.

Hastening Slow Collections.

That a successful plan bearing on this important matter would be of great interest to many old and new business men is beyond a doubt. In consequence we give below a letter from an old reader, asking for some suggestions that would help him. The remarks on it were furnished by another reader who has had an opportunity to confer freely with a great number of men in need of similar information and who has employed various methods with varying success over a wide section of country. The inquiry is as follows:

"The past year has been a prosperous one to me, with plenty of work at paying prices. The only complaint is slow collections. Will you kindly solve for me this difficult problem: What is the best possible way to approach the customer who is slow in his payments, to receive our pay, retain him as a customer and not be guilty of giving him offense? That an effective method would be hailed with delight by many of your subscribers as well as myself is assured."

Commenting on this another subscriber writes: "No idea is entertained that your correspondent will find in the following observations and suggestions an infallible solution to his problem, but trust is felt that he and others may find them of some use. It is assumed that he not only runs his buying and selling himself, but keeps his books and works at his trade inside and outside as well. In learning the trade it was learned that ten hours was a day's work, but on going into business it was found that 16 hours was nearer the mark. These 16 hours should be divided into halves—eight hours for hand work and eight hours for head work, and of the two the last half should always have the preference and should never be subservient to the other half. First-rate hand work can always be bought at from $2 to $3 per day. Head work, which is to be up in the morning clear headed to see that everything that is needed for the day's work is ready for the men to start off with, cannot be hired, especially when this same head must plan for them the next day and waste neither time nor material, receive their report at night and give them their orders, besides buying and selling. Now this part of the head work should be done quickly, for it must not be allowed to take more than one third the head work half.

"The next thing, then, is charging up and keeping the books so that the chore boy can tell a customer how much he owes. This should be correctly and carefully done, for it is preliminary to the most important work of all. The all essential and most important work is making out the bills, delivering them and making collections. Consequently half of the time of the head work half of your day should be devoted to it, letting the labor half suffer if your mathematics cannot be made to correspond with the limit. I would impress you with the importance of the trade of bill making and collecting, which is a trade in itself, and one which it will pay you to learn. Bill collecting is generally considered a disagreeable job by those who do not recognize it as a trade, and work at it as a trained workman would and must to be successful.

"The first point is in charging up, for most people enter a protest against a large bill, the items of which they cannot remember, so if your charge is full and has a memorandum explaining some incident that the customer can connect with the items it will be found an advantage when read on the bill. Now, when you buy often you receive a bill before the goods, and on it a notice that no claims are admitted after five days, also —— per cent. off for cash in a few days, and in some cases, where goods have a long distance to travel, a further notice states, 'All goods shipped at owner's risk,' and immediately on getting the shipping receipt the goods are yours, and the bill is immediately due and collectable. That is business! You are in business! Why not do business in a businesslike way?

"Send a bill as soon as the work is done. Many people are prepared with the money to pay a bill for work they order done, but if you wait a long time before sending a bill they spend the money and your bill reminds them that if you had sent it when you ought it would not annoy them now, and as you have made them wait for the bill you can wait for the money, which is working the rule both ways.

"Send the bill at once, because some people want to save up from their income enough to pay it, and they don't start to save till they know how much it is, and the longer you wait the longer you'll have to.

"Send the bill at once, so a chronic slow payer can be begun on sooner.

"Send the bill at once to a business man or corporation, as they may have special pay days, and if you miss one you will have to wait till the next; so make a note of their pay day on your charge books, ledger and bills.

"Send the bill at once, while the work done is fresh in the mind of your customer, so he can see if all the items are fair and that you have not waited till he forgot, and put in some.

"Send your bill at once, so that if it is lost it can be replaced by another as soon as you find it out.

"Enter your customers' names and the amounts they owe in a pocket ledger and carry it with you, for you can often collect a bill in this way from a man you seldom see, and can give him a receipt and mark it paid on your book while he sees you do it. Some bills have proven easier to collect with the following printed in neat small type in the lower left-hand corner when it is truly carried out:

GOOD WORKMANSHIP, MATERIALS AND TREATMENT MAKE COLLECTIONS.

Please examine the items and report any errors, so they may be corrected at once. Collections made 1st of every month.

"All this preliminary work helps to approach the customer who is slow in his pay. He has had his bill and knows that you want your money on the 1st of the month, that you are willing to correct any errors and that he has received your best work with good materials and has had good treatment. Now, don't fail to see him on the 1st of the month; if you do not it is your fault and gives him a chance to say he supposed you intended to let it go over another month as the work was only just done. Never lose sight of the fact that he did you the favor when he gave you the order, but the favor was transposed and he received the favor the minute that your time, labor, skill and material completed his work and you have as good as loaned him money to the extent of your bill. Thoroughly understand this fact and truth and it will give you confidence to maintain it in a quiet, dignified way, which will impress him. You may tell him that while you always like to collect your bills at the date set, to save further time and trouble for both, you are willing to grant him the favor of another month if he needs it, and that if he prefers he can make a payment on account at any time it is convenient for him, but to come and see you if the promise he is then making becomes impossible to keep, and to let you know what further proposition he has to make. He will see from this that you intend to have the money, that you are disposed to be fair in your treatment, and that you are willing to be generous in the future. Tell him if he has any other work to send in the order, also if he knows anybody that wants anything in your line you would be glad to be recommended if he feels that he can, for your friends are your best-paying advertisements. This will gain his confidence and that is what you want, for if you once get that he cannot withhold the cash or make no provision to pay you.

"If after such a manly, quiet and honorable usage you lose his trade and he feels offended, you made a mistake in trusting him at all. Before you put it down to profit and loss, however, go and tell him that you have done all that you think is required of you, but before you entered suit you came to hear what he had to say, for you know you can get a judgment which will increase the bill to him and is a useless expense, and that you will give him a week to come and pay up, after that time you will sue."

The Watkin Tower.

Ever since the Eiffel tower in Paris was found to have turned out a success there has been a lurking feeling in England that she ought "to go one better." In 1890 the project of building a tower which should overtop the great Parisian structure took practical shape, and a company was formed, the principal promoter of which was Sir Edward Watkin, the well-known originator of the channel tunnel scheme for connecting England and France. The chief engineers of the world were invited to offer designs, and some sixty or seventy competitors from every part of Europe and America sent in competitions for the prizes of £500 and £250, to be awarded to the two most meritorious plans. The design selected as the best has, with some modifications, been adopted.

In regard to the project, *Iron* says: "As the contract for the metal has now been placed, it may be expected that work on the great tower at Wembley Park, London, will shortly be proceeded with. The erection, which is to eclipse anything of the kind that has ever been attempted, is to be entirely constructed of steel, which is to be furnished by the Stockton Malleable Iron Company. It will be 1,150 feet high above the base, which will rise 162 feet above the level of the grounnd, and it will, therefore, exceed by some 150 feet the hight of M. Eiffel's celebrated Parisian structure. Messrs. Heenan and Froude of Manchester are building the tower."

The tower is stated to be of very graceful proportions. It will contain a central hall for dancing, of 20,000 feet area and 60 feet high, and will also possess a hotel with 90 bedrooms. Work has been already begun on the foundations. Wembley Park, in which it will stand, is an inclosure of 280 acres, situated between Willesden and Harrow. It can be reached by rail in 10 or 15 minutes from the center of London. Sir Edward Watkin, the projector of the undertaking, who is one of the most enterprising and progressive of Englishmen, notwithstanding his advanced age, promises that the structure shall be completed before the end of next year.

The plans for the new Third Avenue bridge across the Harlem River have been approved by the Board of Estimate and Apportionment and will doubtless be acceptable to the War Department. Including the approaches, this bridge will cost about $2,000,000. The total length of the bridge and approaches will be 2324 feet. The bridge will be built of iron and steel, and the approaches will be built of iron and masonry. The central swing span, which will be of steel, will be 300 feet long, and each side of the draw will be 104 feet in the clear. The bridge will have a width of 86 feet. The channel spans will be 26 feet above high-tide mark.

It is noticed as a curious fact that while paper is displacing wood in the manufacture of many articles, wood is displacing the materials formerly used in the manufacture of paper.

Crane's Compression Fire Hydrants.

Illustrations are herewith given of improved forms of fire hydrants manufactured by Crane Company, 10 North Jefferson street, Chicago. The standard compression hydrant, shown in Figs. 1 and 2, has leather-faced main valves, closing with the pressure. This form of valve is used with great satisfaction in nearly all the large cities and towns. The construction of the valve and seat is such that it is not necessary to shut off the water to renew a broken stand pipe, as the valve seat is set in the The brass plungers close the discharge ports as the main valve is opened. The arrangement is such that no frozen waste water can stop the use of the hydrant. The important feature of making repairs very easy has been carefully studied The illustrations enable the interior construction of this hydrant, as well as its exterior, to be thoroughly grasped by the reader.

The Crane Company state that they were the first to engage in the manufacture of hydrants for auxiliary pipe lines to be used in connection with fire boats in extinguishing fires located some distance from the docks. By the means of these when not in use, as there is no circulation to prevent the water freezing; consequently no main valve is required.

Fire hydrants with more than one nozzle are now made by this company with independent gates at each nozzle, operated by a simple device of their own invention. As illustrated in the sectional view, Fig. 4, this device consists of a small gate sliding in guides back of the nozzle. A jointed arm connects the gate with a crank which is turned by a wrench applied to an operating nut on the outside. It cannot be turned the wrong way, nor can the valve be forced beyond its proper position and damaged. The operating nut is similar to the nut that operates the valve stem, and does not detract, but rather adds to the general appearance of the hydrants. The valve is simple, and will adjust itself to any small irregularities of the guides, which forces it to its seat at the proper time. When the valve is opened the water way is clear and unobstructed in any way. Every valve is in-

CRANE'S COMPRESSION FIRE HYDRANTS.

base, independent of the stand pipe, the water pressure holding it to its seat. It is therefore claimed to be perfectly safe from danger from discharging water on account of a displaced or damaged valve. To prevent damage from the exertion of an unnecessary amount of strength in closing the valve, which is usual, a hexagon nut fastened to the rod immediately under the stuffing box may be torn loose without injury to the hydrant, as the drip yoke is loosely collared on and allows the stem to turn. The waste valve is of solid brass, positive in action, with no leather facings to wear and no intermediate mechanism to get out of order. It is double, so that the barrel drains in one-half the usual time. pipe lines and hydrants the powerful engines of the fire boats can be made available to aid the ordinary department. These hydrants, a sectional view of one being shown in Fig. 3, are chiefly made for hose of 3½ inches internal diameter, a single line of hose often doing as much as four to five lines from the ordinary steamers. The hydrants are also provided with independent gates at each nozzle, but have no main valve. The connections between the mains and the hydrants are made with elbows of long radius, reducing the frictional loss to a minimum. The fact that these lines are liable to remain unused for long periods of time renders it necessary to drain them during the winter months terchangeable and does not depend on the water pressure to hold it tight.

Canadians who have been shipping cattle in bond from Boston to Liverpool have been notified that they can do so no more. Until the opening of navigation by the St. Lawrence River Canadian cattle are shut out of the British markets by the scheduling order of last fall and are shut out of the United States markets by the American quarantine order.

The cities of St. Paul and Minneapolis have a combined population exceeding 350,000.

STEAM AND HOT-WATER.

One Large or Two Small Boilers.

From S. S., *Marcellus, N. Y.*—I wish to ask a question through your columns on steam heating. Suppose I have a large building to heat, say 48 x 80 x 12, two stories high; which would be regarded as the more economical, all points considered, to heat the entire space with two heaters, one for the upper floor and one for the lower floor, or one large heater capable of heating the entire building, the price of heaters not to be considered? The point to be covered is this: Is one large fire more economical than two small ones for steam heating; if so, why? The heaters to be placed in the cellar in both instances.

Answer.—Our correspondent describes the situation of the building, &c., but in conclusion he asks whether one large fire is more economical than two small ones, and the answer to this question is, Yes. Other things being equal, it is better policy, so far as the fuel consumption is concerned, to use one large heater. The combustion is always better in a large grate than in a small one, as it has proportionally less cooling surface in direct contact with the fire. The coal immediately against the brick or iron, as the case may be, does not burn as thoroughly or efficiently as the coal in the middle of the grate. It must be borne in mind, however, that there are several other reasons why it may often be desirable to use two fires instead of one. There is a better regulation of the temperature in mild weather when a large fire will give too much heat and there is the extra boiler to be used in case one is disabled. In speaking of the relative economies of large and small fires, it is to be assumed that both fires are kept burning briskly. In a dull fire where there is a great deal of waste due to the escape of unconsumed gases, there is less to choose between a large and small grate.

Care of Steam Heater in Summer.

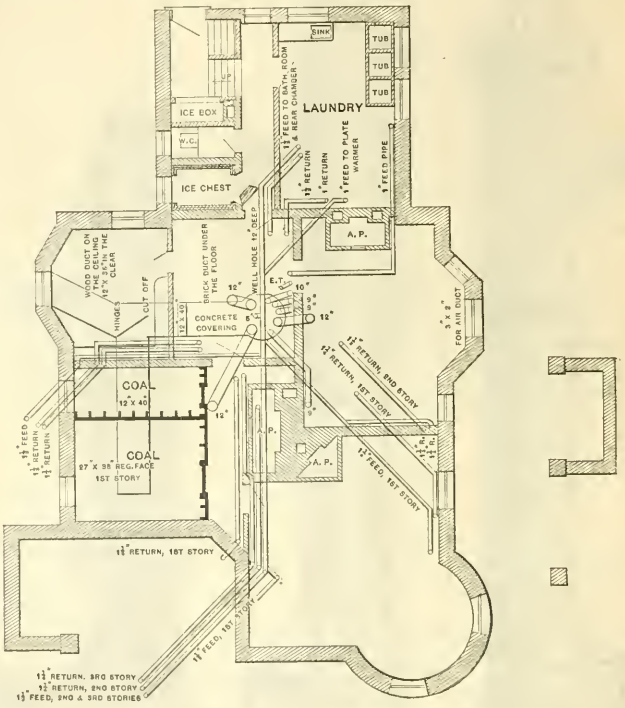
From "B. C.," *Shamokin, Pa.*—In one of our school buildings we have a steam heater. One of the directors is in favor of emptying the boiler when it is not in use during the summer, leaving all the valves open, so that the air can circulate through all the valves and pipes and keep them dry and preserve them. The other directors claim that the system should be kept full of water. Which is the better way?

Answer.—The second suggestion is to be preferred—namely, that the boiler and system of piping should be left full of water in the summer time. While one would suppose that drawing off the water and leaving the system dry would be likely to preserve the iron better, yet the fact is that dampness accumulates within the pipes and the simple act of drying has a very corroding effect. When iron is kept completely submerged in water the corrosion is comparatively small. Our correspondent can test this from his own observation, where an iron rod or plate has been partially submerged in water for a long while. The portion that is completely covered will be found less corroded than that part between the air and the water where it is alternately wet and dry and subjected to both the action of the water and the air.

Combination Hot-Water and Warm-Air Heating.

The combination hot-water and warm-air method of heating is very popular with some people, and, in addition to the pleasant heat furnished, is said to be economical in coal consumption. The direct hot-water heat being used in rooms remote and the warm-air (or indirect) being connected to the halls and rooms immediately over the heater, secures the degrees of heat required in any condition of the weather.

We illustrate herewith the heating arrangements of a residence, situated at Glencoe, Ill., on the lake shore, 90 feet above the level of the lake. In Fig. 1 is shown the basement plan, in Fig. 2 the first-floor plan, in Fig. 3 the second-floor plan and in Fig. 4 the plan of attic. The working plans for the heating were made by the Chicago branch of the Magee Furnace Company, the heater being a No. 51-2 Magee Boston heater with six hot-water sections.



Combination Hot-Water and Warm-Air Heating.—Fig. 1.—Basement Plan.

The water in this heater, it is pointed out, has a vertical circulation, and the fire pot is constructed with water sections and fire brick alternating.

As shown in basement plan, Fig. 1, the heater is located in as central a position as possible, set on a foundation of brick and cement, 12 inches deep, with a brick arm extending underneath the cement floor to partition, to receive the cold-air duct, which is made of wood on the ceiling running to an opening in the west wall.

The cold air duct is also connected with the cold-air register in main hall. Both ducts are operated by one cut-off, so arranged that air cannot possibly be closed off from the heater. The cut-off is operated in boiler room, by a lever at the side

of heater. This method of constructing the cold-air duct is desirable because fuel is saved by closing the duct at night.

The size of the hot-air pipes are all shown in the engravings.

In the first-floor plan, Fig. 2, the dining room, music room and hall are heated by indirect, or warm air, and the sitting room and butler's pantry by direct hot-water radiation. The size of warm air stacks and hot-water risers to third floor are marked on the plan. On this floor two chambers over the dining room are heated with warm air, and the sitting-room chamber, music room chamber, rear chamber and bathroom by hot water. The size of registers and number of square feet of radiating surface in each radiator is marked on the plan.

In Fig. 4 is shown the location of registers and radiators on third or attic floor. The size of registers and pipes, and the number of feet of radiating surface in each radiator, are shown in the plan. On this floor warm air is used in the dining-room chamber and hall, and hot water in the sitting-room and music room chambers.

The expansion tank is located near the ceiling, at point marked on plan, and connected to waste by a 1-inch overflow pipe, so that in case the water becomes overheated it will escape. There is a vent at the highest point of the overflow pipe to prevent syphoning. The tank is connectcd to heater by a separate pipe running to basement, which connects near the heater with a return from one of the radiators. To fill the system, a force pump is provided in basement from whence the water is pumped through the tank to attic. There is an altitude gauge in basement near force pump, to show the hight of water in the system.

In setting a combination heating plant

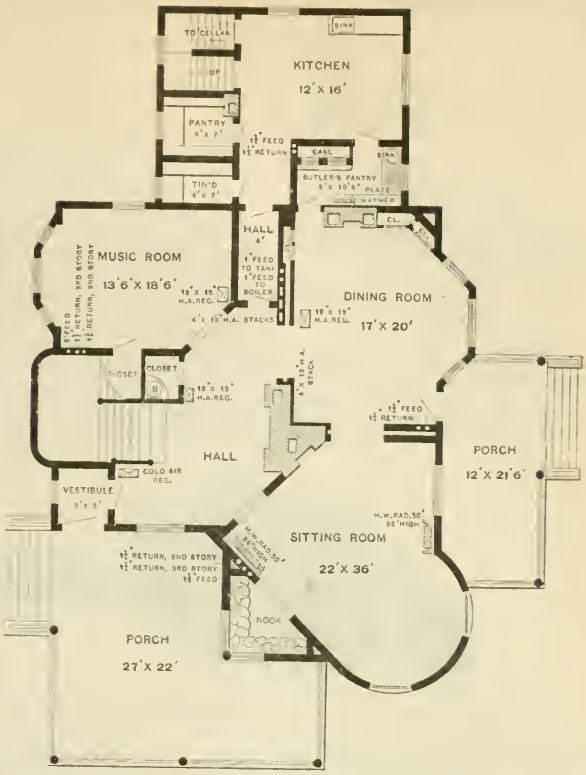


Fig. 2.—First-Floor Plan.

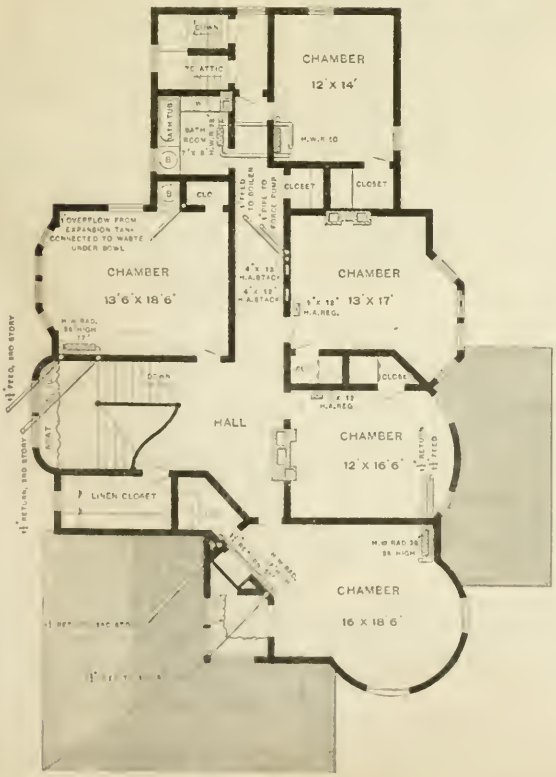

Fig. 3.—Second-Floor Plan.

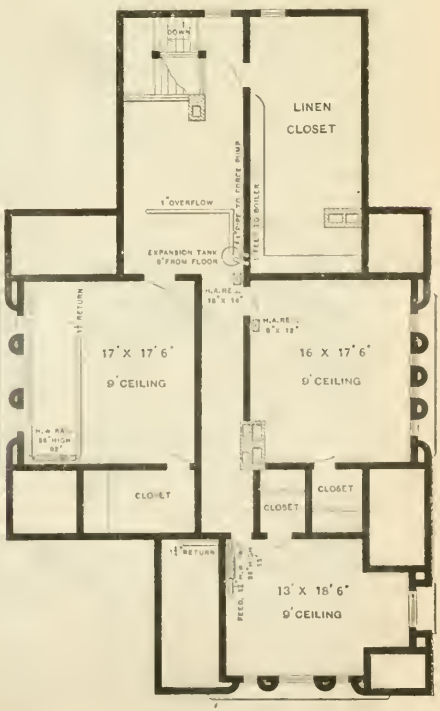

Fig. 4.—Attic Plan.

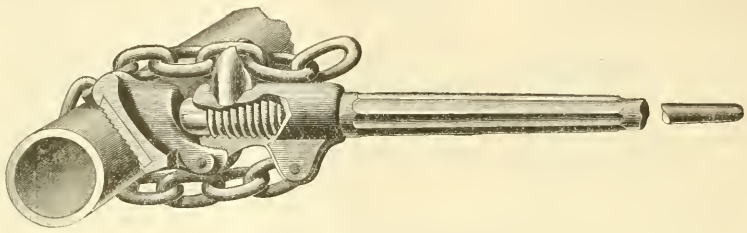
the principal difficulty to be overcome is adjusting the hot water and warm air so they will heat evenly. In the Magee heater, sectional hot-water heaters are used, which are made to heat from 85 to 167 feet of radiating surface, exclusive of mains. One of these sections, of any size, can be added to or taken from the boiler at pleasure.

In piping for a combination system, we find it necessary, in a great many instances, to use larger mains than is commonly used with a hot-water heater. This is done to get the quickest possible circulation and to avoid overheating the hot air in mild weather.

Hilts' Adjustable Chain-Pipe Wrench.

E. F. Keating, 75 John street, New York, is introducing the above wrench for the Roll Paper Cutter Company, Richford, N. Y., as shown herewith. The wrench has a traveling handle, so that after the chain has been passed around the pipe and fastened, one turn of the handle will take up the slack in the chain. The grip on the pipe is immediate, thus giving maximum results in minimum space and time. The wrench has a ratchet motion, and can be removed from the pipe without having to raise or lower the handle. It is well adapted for working in contracted places. The point is made the ordinary chain wrench has been considered powerful and practical, the difficulty with it being the lost motion required to grip the pipe. This difficulty, it is claimed, is entirely overcome in this wrench. The wrench is made in six sizes, for pipe from 1 inch to 16 inches, with lever from 26 inches to 80 inches in length.



Hilts' Adjustable Chain-Pipe Wrench.

HEATING NOTES.

Thomas C. Andrews, New York City, is the patentee of a steam or water heater. The boiler, as claimed in the patent, comprises a plurality of superimposed sections with a central heating compartment in the sections; a hot-water chamber around the heating compartment in each section, and all made to communicate.

We have been favored with a very pretty glass paper weight, advertising the products of the American Radiator Company, 111 and 113 Lake street, Chicago. The trade mark of the company and sundry allusions to the character of their radiators are permanently attached to the under side of the article, so as to be constantly in sight.

Frank W. Somers, 88 Lake street, Chicago, Western manager of the A. A. Griffing Iron Company, manufacturers of the Bundy radiators for steam and hot water, reports business unusually good for this time of the year. The Bundy radiators are to be used in the World's Fair Hotel, Raymond flats, new depot of the Illinois Central Railroad at Twelfth street, and many other flat buildings, churches and residences in Chicago.

The Japanese Building at the World's Fair is to be heated by means of an Economy hot-water heater, manufactured by the J. F. Pease Furnace Company, Syracuse, N. Y., and supplied by Geo. D. Hoffman, 82 Lake street, Chicago.

Geo. D. Hoffman, 82 Lake street, Chicago, is to supply the steam-heating plant for the large eight-story apartment building owned by Judge Grosscup, at Forty-third street and Grand Boulevard.

The Excelsior Steel Furnace Company, 110 to 114 South Jefferson street, Chicago, have issued a very neat 16-page catalogue of radiators, which they are putting on the market. They control for Illinois and other Western States the Brown Patent Improved Flue Radiator with all cored surfaces, manufactured by the Corry Radiator Company of Corry, Pa., under the patents of R. F. Brown. The system of radiation employed is the result of long and costly experiments and the manufacturers claim very great advantages from the use of radiators of this description. One important claim made is that these radiators secure great economy of floor space, which will be appreciated by architects and house owners in cases in which the saving of room is important. Illustrations are given in this catalogue of a variety of styles, shapes and sizes of radiators adapted to different locations, as, for instance, for ordinary situations, for windows, for circular windows, &c. They manufacture an attractive line of patterns in artistic decorations, as well as in plain styles. Announcement is made that during the year 1893 a line of indirect radiation will be placed on the market, which, it is claimed, will possess many advantages. Tables are published giving the heating surfaces of each section of the different sizes of radiators manufactured, together with full price-lists.

We have a pleasant letter from E. N. Squires, secretary of the New York Central Iron Works Company, Geneva, N. Y., inclosed in which is a very novel novelty in the advertising line. It is a toothpick built out of celluloid and bearing a very close resemblance to the natural quill. The versification talent that this firm have often displayed is exemplified in the present instance with the couplet :

"Take your pick and get the best.
Choose the Dunning and leave the rest."

This simple little poem, together with the address and name of the company is printed on the quill.

A number of leading machine makers have just established a limited liability company, "Technical Office of German Machine Makers," in Hamburg, with the object of pushing the exports of machines.

The *Inter-State Grocer* says that in 1892 the wholesale grocery trade of St. Louis showed an increase of 12½ per cent. over 1891 in the value of goods sold. The greatest increase was in coffee.

The American Lamp & Brass Company.

An event of great interest to the lamp trade was consummated last week at Trenton, N. J. It was made public that three of the largest concerns in the United States had consolidated into an organization devoted exclusively to the manufacture of lamps. The establishments alluded to, which have been amalgamated under the title of the American Lamp & Brass Company, are the Great Pioneer factory of Swann & Whitehead, the Great Empire factory of Swann, Whitehead & Clark; and the Clark Bros. Lamp, Brass & Copper Company; all of which are located at Trenton. The capital stock of the new company is given as $1,000,000. It is stated that the main object in effecting the consolidation has been to make the practically unlimited capacity of the three large establishments available for a still larger output of lamps, by making the three great factories distinctly individual departments of one great factory, and thereby creating a better and more economical system of operating them. The new arrangement is said to be in no sense a trust or stock jobbing scheme, as none of the company's stock will be put on the market. The union of these companies will give them greatly increased advantages in the manufacture and marketing of their products, which are already well known the world over.

The officers of the American Lamp & Brass Company are: W. R. Whitehead, president; P. K. Clark, first vice-president; J. Y. Clark, second vice-president; F. B. Clark, secretary, and Charles Clark, treasurer. The decorating department of the concern will be in charge of Frederick Swann, and W. S. MacLewee will superintend the metal department. The above named, with the addition of J. S. Clark and W. S. Clark, are the incorporators of the new company.

A bill modifying foreign bills of lading, with the design of protecting American shippers, is likely soon to become a law. The present bills of lading are full of exemptions in favor of the carrier which crept in in times long past, when the risks of ocean carriage were much greater than now and when the carriers were in a position to dictate their own terms to shippers.

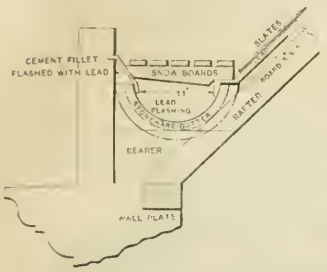
Grand Master Sargent of the Brotherhood of Locomotive Firemen contradicts the reports circulated from Chicago that a general strike is contemplated. He says: "There could not be a strike without disrupting the Brotherhood of Firemen and the Brotherhood of Engineers. The constitutions of these orders absolutely prohibit anything of the kind, and I know it to be a fact that were a general strike permissible the men would not be in favor of it."

Halifax papers chronicle another deal in Nova Scotia coal mines by American capitalists.

ROOFING AND CORNICE.

Durable Gutter Construction.

A rather novel form of gutter construction is that recently brought out by an English manufacturer, and which is shown in cross section in the accompanying illustration. The gutter is made of stone ware with lead flashings, and is covered in such a way as to keep the trough from clogging. The gutters are manufactured in a variety of decorative designs, and are supported on molded Ruabon bricks, which are said to be both ornamental and inexpensive. They require no painting, and both the cornice and roof gutters are unaffected by extreme changes of tempera-



Cross Section of Durable Gutter Construction.

ture. The form of gutter construction here illustrated is being placed upon a number of buildings in Atherton, England, and, we understand, with pleasing results. Although the arrangement of parts here shown represent a form of English practice, it may prove interesting, if not suggestive, to many of our readers.

Roofing Contracts.

From J. J. B., *Philadelphia.*—Will not some of your correspondents in the roofing and cornice trade tell us of some of the contracts they enter into; how much they made (on paper) before they started and how much they lost when they were through with it, and what was the cause of it, so that others can avoid just such contracts?

Trouble with a Roof.

From TIN CHIPS.—A new store had been built in town, and there was considerable rivalry between the two tin-shop proprietors regarding who should secure the contract for putting on the tin roof. At last it was decided that Jim's boss should have the job, and great was the rejoicing in the shop over the decision. Jim had never worked on a tin roof, and at last the opportunity was to be presented to show people what he could do in the roofing line. The tin was laid, and the seams pounded down with the greatest care, and when it came to the soldering, then the science came in. Jim resolved that if there ever was a tight roof, it would be the one he was to solder. After the roof was soldered it was swept off clean and each and every seam examined to see that there were no leaks, for, if the roof was to leak, Jim would lose his reputation as a soldierist. After the building had been finished there was a light fall of snow, and almost every one knows there is nothing that will demonstrate a roof's tightness like snow. On this account Jim welcomed the fall of snow, as it would be the means of showing that the roof was perfectly tight. An examination of the plastering under the roof revealed a number of dark spots, and as these spots were produced by water, it did look as if the roof leaked, otherwise what caused the water? Jim cleaned off the snow, and gave the entire roof a very careful examination, but not a leak could be found. The rival tinner—the one who did not get the job—was of the opinion that the work had been improperly done and that the roof would leak as long as rain or snow fell. Jim was sorely perplexed regarding the strange manner in which the roof behaved, as he was certain the roof did not leak, yet there were the wet spots on the plastering. It came about one day that the school teacher came in the shop, and as the subject of the leaky roof was mentioned, the teacher informed Jim that probably the roof was really tight, and that the spots on the plastering were caused by the moisture from below coming in contact with the cold tin. This would cause the moisture to condense and drip through the roof boards on to the plastering. This theory was adopted as correct, and a dark cloud was removed from Jim's horizon.

Slate Deposits.

In a recent issue of the *American Slate Trade Journal* George H. Harris presents some remarks on the subject of slate deposits which may not be without interest to many of our readers. Among other things he says: The analysis of slate shows that its principal ingredients are silica and alumina. Slate is pronounced by many people to be aluminous clay. It contains a small percentage of carbonate and sulphate of lime. Peroxide of iron is also found in slate. Green slate contains but little, if any, iron. The purple and red take their color from the iron they contain. The presence of slate is determined by the outcrop upon the surface. The average citizen with a limited amount of intelligence, possessing the necessary qualifications for success—pluck, perseverance and muscle—is better equipped to solve the problem in regard to the exact location of a slate deposit than is the most scientific mineralogist.

But very few quarrymen, if any, are thoroughly confident of meeting with success in developing the slate quarry. It frequently occurs that the most experienced quarrymen lose their all in some unfortunate venture of this kind, while some inexperienced workman may find the larger bed and larger compensation with little effort. If success in quarrying slate were an absolute fact, and if there was no question regarding the location of the deposit, then a condition of things would exist directly contrary to the present. The laborer would then be the capitalist. The risk which surrounds the average quarrymen makes capital imperative. Time, money, patience and all the modern appliances are necessary and indispensable requisites in slate quarrying.

In order to connect the past with the present, so far as it relates to the original deposits of slate, it might be stated that geologists have been unable to form a continuous history of rocks from the remains of plants and animals found in them. Hence it appears that there is a diversity of opinion among these men regarding the early formation of slate deposits.

One of these gentlemen thus states his opinion regarding slate in its earliest stages, which conforms to natural laws and is as authentic as anything written upon this subject. It is as follows:

"It is said that the slate beds have been formed ages back, at the bottom of the seas, where mud had been washed by rains from the old lands and carried by rivers into the seas. Most of the mud was made up of feldspar, with smaller amounts of lime, magnesia, iron, potash and carbon. The mud deposited in layers or beds in the bottom of the seas, in course of time got covered with other materials. The whole mass, slowly hardened and consolidated by pressure and heat, lifted out of water. It cracked and split in various directions while in process of drying. Influenced by that law of crystallization by which all minerals assume certain shapes, the mass split up into rhomboidal masses. After this came the great disturbing forces by which the beds were bended and twisted in all directions. The great pressure on these lay between the N. N. W. and E. S. E. Between these two points the particles of the mass became flattened and compressed into about half its original bulk, and thus was imparted to an unbroken mass of rock that lay between these cracks and divisional planes that had a tendency to peel off from each other, and is now called slaty cleavage."

There is a great similarity in the location of slate deposits, whether in Pennsylvania, Maine or Vermont. We generally observe the outcroppings of slate on high lands or mountains with a depression at the base, which extends to another range of elevated land. Take, for instance, the slate beds of Vermont and New York, we find that they are located in and about an extensive range of hills, the valley which properly extends from Castleton, Vt., to Salem, N. Y.

The slate section of Vermont and New York is located at the southern trend of the Adirondack Mountains and in close proximity to the Champlain Valley. The valley in which are located the slate deposits varies in width from 1 mile to 5 miles and narrows down at the northern extremity, leaving but a limited space for travel between two mountains previous to entering the Otter Creek and Champlain valleys, lying at the base of the Green Mountains. From their sides are taken marble, granite and other minerals. This range forms the eastern bulwark of this great valley, while the Adirondacks perform a similar duty on the west side of the Champlain Valley.

The Adirondacks commenced their duties at a very early period in the geological history of the earth. They belong to the Archæan age—sometimes called the iron age on account of the presence of iron. Graphite, granite, mica, schist, hornblendic rocks and crystalline limestone are the principal mineral deposits of this range of mountains.

Designs in Slate Roofing.

In our issue for February 4 we presented illustrations of a number of designs in slate roofing taken from an English architectural journal. We give below additional designs from the same source, remarking in this connection that the combinations of slate may be varied al-

just what has been previously mentioned and described, but the ordinary courses fill in between the diagonal lines in a different way. A little care in starting each of the varieties is all that is required to enable any intelligent workman to manage each of these patterns.

A little center pattern is given in Fig. 34. A dark slate, cut as in Fig. 37, is in the regular roofing slates are reached. To work out this design the only shapes necessary are those shown in Figs. 40, 41 and 42, and their arrangement is distinctly shown in Fig. 39. In the next two diagrams, Figs. 43 and 44, other designs are shown, worked out with the same detail as in these previous examples. A pattern of the same style, but much larger, is

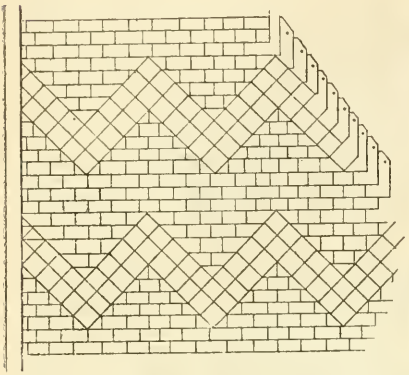


Fig. 31.—A Unique Combination of Cut and Uncut Slate.

Fig. 34.—A Neat Pattern.

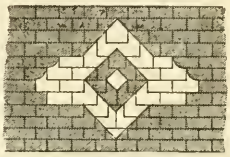

Fig. 43.—Design varied from Previous Examples.

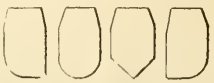

Figs. 35 to 38.—Slate Used in Producing Pattern Shown in Fig. 34.

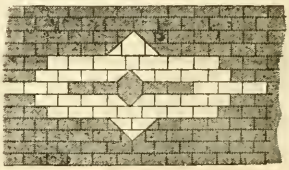

Fig 44.—A Pleasing Design of Light and Dark Slate.

Figs. 40, 41 and 42.—Shapes Required to Produce Pattern Illustrated in Fig. 39.

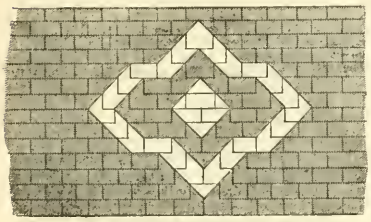

Fig. 39.—A More Elaborate Design.

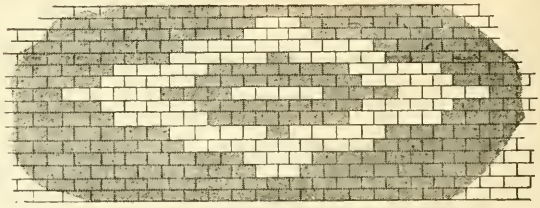

Fig. 45.—Design Made Without Cut or Shaped Slate.

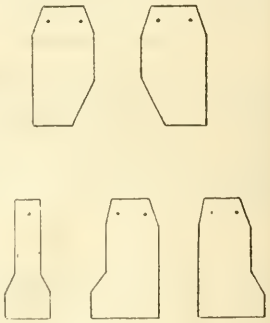

Fig. 47 to 51.—Forms of Cut Slate Used in Making Letters shown in Fig 46.

DESIGNS IN SLATE ROOFING.

most without limit, according to taste and requirements:

Before considering a totally different style of ornament, an example recently seen by the writer may be noticed. It consists of diagonal bands of shaped slates, with a few ordinary courses between each diagonal band. In Fig. 33 will be seen exactly what is meant. The shaping is

center. The light slates surrounding it are variously cut, both to the round-cornered shapes, Figs. 35 to 38, and to the beveled-cornered shape.

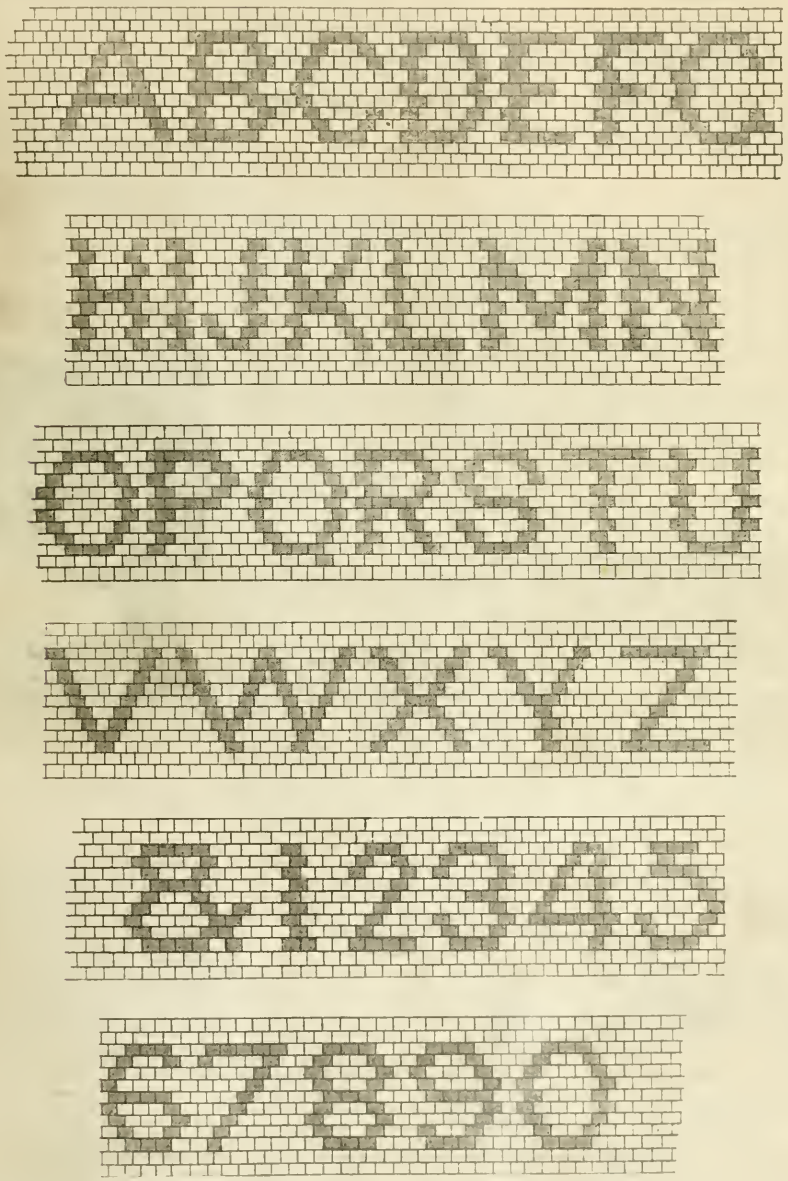
Some of the common slates outside are also cut as shown in these figures. A more elaborate example is given in Fig. 39, where the center is light; next is a series of dark slates, and light again before the

given in Fig. 45, and in this it will be noticed that there are no cut or shaped slates at all—all are of the usual square form.

It is sometimes desired to have a firm's name shown in the roof of a warehouse or workshop, and this, though usually managed by means of the paint pot, can yet be arranged in the slating.

It is, perhaps, a little troublesome to manage, especially if the name be such as Macfarlane, Fotheringham, Sons & Co. This would require an immense length of roof to accommodate it. But it is just as well all firm names are not so bulky. The letters require about seven courses of slates further up in the same letter. These, it will be noticed, are for nine courses of slates.

All the letters of the alphabet may be easily formed from A R O, and worked out in seven courses. For instance, B may be almost wholly found in R, C in O and D in R, &c., while the diagonal of A will be required in such letters as M, N, V, W and Z. These are all arranged with square-cornered slates of a darker or lighter color than those of the rest of the roof. A complete alphabet and set of numerals, shown in Figs. 52 to 57, inclusive, are given for the use of any one who may want to work a name in a roof. There will then be no difficulty whatever in arranging any name required. Then, though this alphabet is for nine courses, the seven course one is arranged in the same way as this. With these remarks and accompanying sketches we hope it has been made quite clear that ornament in slating work may be much more frequently introduced than it is, to the great benefit of the public at large.



Figs. 52 to 57.—Alphabet and Numerals Made by Using Slate of Ordinary Shape.

DESIGNS IN SLATE ROOFING.

to form them respectably. In Fig. 46 is given a sketch of three letters, A R O, worked out in slate cut as shown in Figs. 47 to 51. It may be wondered where Figs. 50 and 51 go. An examination of Fig. 46 will show, however, that they are required immediately above the cross of the A. Fig. 49 is required just a little

---

The Cortright Metal Roofing Company of Philadelphia have changed the address of their Western office from 134

Van Buren street to 84 Adams street. The company state that their Western trade has largely increased during the past year, necessitating better facilities for conducting the business, which is the reason for the change in their location.

FLASHINGS.

SEALED PROPOSALS will be received at the office of W. J. Edbrooke, Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock p.m., February 28, for the labor and materials required for the cut stone and brick work, iron and wood floor, slating and roof construction and roof covering for the superstructure of the United States Post Office building, Burlington, Iowa.

A POSSIBLE NEW MARKET in the sheet-iron trade may open up in the far East. We learn from an English exchange that galvanized sheet iron appears to be coming into favor as a roofing material in China. The use of this metal has hitherto been confined to some of the provinces, but it now being adopted in Peking itself. Galvanized sheets will, we are told, be used for covering the large iron railway station which is to be built during the coming summer in Tientsin, the port of the Peiho River open to foreign trade, and the Chinese Government have called for tenders for this work from any quarter. Intending competitors can obtain all particulars of the contract from R. M. Brown & Co. of Tientsin.

GEO. C. KEENE & CO., 148 to 150 East Front street, Cincinnati, Ohio, report the demand for their productions as being excellent and are running their plant full. Among recent goods shipped are carloads of roofing machinery to the Berger Mfg. Company, Canton, Ohio; a 10 foot cornice brake to the Sims Mfg. Company, Newark, Ohio, and a 10-foot corrugating machine to Cambridge Roofing Company, Cambridge, Ohio.

THE INDUSTRIAL EDITION of the *Easton Express*, Easton, Pa., contains some interesting details respecting the slate quarries, at Bangor, Pa., which are being operated by the Bangor Excelsior Slate Company of Easton. The company are working two extensive slate mines, the Bangor Excelsior and the Bangor Royal, the property of R. S. Brown, of which the yield during the past year was 24,000 squares. Considerable additional facilities have, however, been recently introduced for the more rapid mining and handling of the material, and the output is consequently expected to be largely augmented during the present year. The quarries are stated to be thoroughly equipped with all the latest mining devices in the way of steam drills, derricks, conveyors, &c., operated by steam or electric power; and the roofing slate is all made on the spot, complete and ready for direct shipment.

E. E. SOUTHER & BROTHER of Nos. 932-936 North Second street, St. Louis, Mo., favor us with a copy of a neat catalogue of 32 pages, illustrating and describing their roofing specialties. The firm give attention to corrugated iron and steel sheets for roofing, siding and ceiling, pressed standing seam, V-crimped and roll cap roofing, gutters, corrugated down spouts and pressed steel brick. With reference to their corrugated iron the firm state that all their sheets with the standard 2½ inch corrugation are 26½ inches wide when finished, and lay exactly 2 feet wide after lapping one corrugation. They make sheets from 4 to 12 feet in length, of the best box annealed iron or steel, especially adapted for corrugating. The catalogue is profusely illustrated, the engravings being clear and distinct, while the descriptive letter press includes directions for laying the Climax roof, as well as giving other particulars of interest to those engaged in the roofing trade.

THE AMERICAN ROOFING COMPANY, with office at 1505 South Second street, St. Louis, Mo., are distributing a hanger bound with metal strips and arranged with an eye for suspending it upon the wall. Printed upon a floral design is a panel carrying a number of illustrations of corrugated iron, roll and cap roofing, steel-pressed brick, shutters and doors, and curved corrugated iron or steel. The poster is lithographed in colors and likely to attract attention wherever it may be exposed to view.

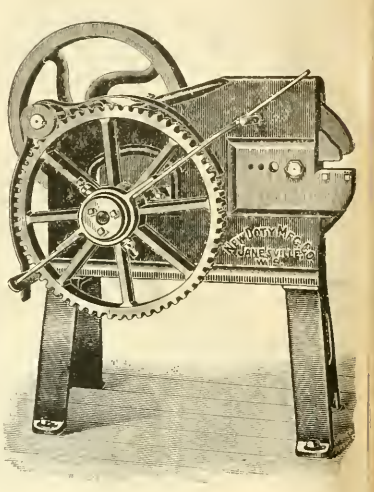
The Small Arms of the Great Powers.

The newest small arms of the Great Powers are of the following calibers: Austrian Mannlicher, 0 315 inch; French Lebel, 0.315 inch; German Mannlicher, 0.311 inch; British Lee-Metford, 0.303 inch; Russian Mouzin, 0.300 inch, and Italian Carcano, 0 256 inch. The weights of the rifles, without bayonets, are: Austrian, 9.6 pounds; French, 9.2 pounds; German, 8.3 pounds; British, 9.2 pounds; Russian, 9.5 pounds, and Italian, 8.2 pounds. Several of the powers now supply to each man 150 cartridges. Assuming this to be the number all round, the weight is: Austrian, 9.8 pounds; French, 8.1 pounds; German, 8.9 pounds; British (black powder), 9.2 pounds; Russian, 7.7 pounds, and Italian, 7.1 pounds. Thus the caliber of the rifle, as a rule, regulates to an important extent the total weights to be carried by the men in action. Putting aside bayonets, cartridge boxes, magazines and other equipment, the Austrian soldier, whose rifle is of the largest caliber, carries in rifle and 150 cartridges a weight of 19.4 pounds, while the Italian soldier, whose rifle is of the smallest caliber, carries in rifle and 150 cartridges a weight of only 15.3 pounds. The British rifle and ammunition are, however, too heavy in proportion to the caliber, and the result is that, although the British soldier uses a bullet of less caliber than the Austrian, the French or the German soldier, he carries a greater proportionate weight in rifle and ammunition than any soldier except the Austrian. It may be added that Belgium has adopted a caliber of 0.301 inch, Roumania, one of 0 258 inch; Spain, one of 0.295 inch; Turkey, one of 0.301 inch, and Switzerland, one of 0.295 inch. Belgium, Spain and Turkey use the Mauser principle; Roumania uses the Mannlicher and Switzerland uses the Schmidt.

According to the *Engineering News*, the use of meters at Detroit, Mich., has shown some remarkable results. It has effected a reduction of the daily *per capita* consumption of water from 204 gallons in 1888 to 140 gallons in 1892, about 31 per cent., and has so reduced the pumping expenses as to make the operating expenses for 1892 actually $2251 less than for 1888, notwithstanding an increase in population estimated at 46,000 and an increase in families supplied from 36,863 in 1888 to 46,400. While the population increased over 40 per cent. from 1888 to 1892, the total yearly consumption decreased nearly 15 per cent. L. N. Case, secretary of the Detroit Water Board, estimates that in the past four years the meters introduced have saved, in pumping expenses and interest on enlargements of the works, otherwise necessary, about $235,000. In addition an ever increasing extravagant waste, restrained only by lack of capacity of the works, has been stopped and the *per capita* consumption has for four years been going steadily downward, instead of upward. Until the consumption is reduced to at least 100 gallons *per capita* the water commissioners of Detroit, it would seem, cannot begin to rest contented with the results of their efforts to save water, for of 39 of the 50 largest cities of the United States, excluding Detroit, the daily water consumption of 31 was below 140, and of 21 below 100 gallons *per capita*, while 14 of these cities had a consumption of only 75 gallons or less, and 5 were below 50 gallons.

The New Doty Shear.

The accompanying engraving represents a new shear brought out by the New Doty Mfg. Company of Janesville, Wis. It is especially adapted for cutting bar iron, either flat or round, the machine shown—the smallest size built—cutting 3 x ½ inch flat bar, or 1-inch round. The knives for flat and round iron are independent of



The New Doty Shear.

each other, and both sets of knives are at all times ready for use without any change. The round iron knives are made the reverse of the iron, and do not flatten it in cutting. The machines are made very strong and powerful, and do their work easily. All boxes are cast solidly on to the body of the machine, and there are as few separate parts as possible. The eccentric, eccentric shaft and clutch are all cast in one piece. The balance wheel, shaft and all bolts are of steel. The motion of the knives is controlled by a clutch, which can be operated by hand or foot power.

THE STAFF OF TRAVELERS who will represent the Michigan Stove Company on the road during 1893 embrace the following, who will cover the territory named: Chas. Breasted will travel in the State of Illinois; Henry A. Pope in Southern Illinois; M. E. Mills in Wisconsin; A. S. Dean in Minnesota and Dakota; J. C. Bosworth in Iowa; J. W. Cassell in Missouri and South Iowa; J. F. Farrell in Kansas, Colorado and Texas; Matt. R. Bingham in Nebraska; Fred. H. Warren, Chicago; T. H. Harlow on the Pacific Coast; W. E. Anthony in Northern Michigan; C. H. Millen in Southern Michigan; A. H. Dane in Indiana; A. Saybolt, Jr., in Ohio; F. P. McCanna in New York and Pennsylvania, and G. Holloway in Southern States.

"The Metal Worker" Competition in Skylight Pattern Cutting.

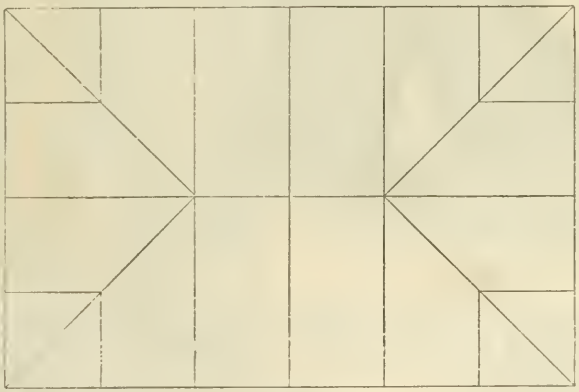
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

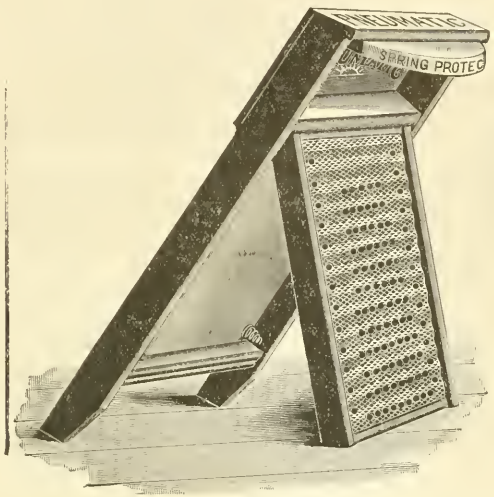
1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

THE RETAIL STORE.

The Pneumatic Washboard.

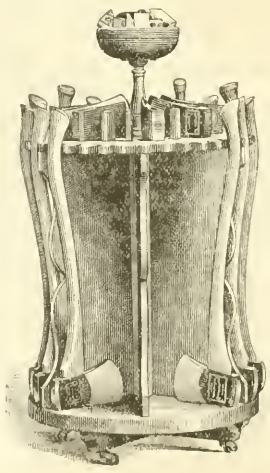
The pneumatic washboard, as herewith illustrated, is being offered by Gorham & Sargent, Cleveland, Ohio. By the construction of the washboard, it is explained, an air chamber is formed under the rubbing surface. When in use the perforated rubbing plate is described as being pressed downward into the air chamber at each stroke of the operator, forcing air, suds and water upward through the fabric that is being washed, thereby thoroughly cleansing the clothes in a short time, and with great ease. The point is made that the yielding to pressure of the rubbing plate, in connection with the air chamber, affords relief to the arms and shoulders of the operator. The board is represented in the cut as after having been used, opened out to dry and shows the air chamber under the rubbing surface, springs, &c. The board is provided with the Peerless embossed rubbing surface, with large and strong pivoted frame, heavy zinc, and the manufacturers claim, combines in one article all valuable features of the best washboards and washing machines.



The Pneumatic Washboard.

A Convenient Axe Stand.

The accompanying illustration shows a convenient form of Axe Stand designed by Samuel H. Blackwell, Fairfield, Maine. It will accommodate six dozen Axes, three dozen with handles and three dozen without. The hight from the floor to top of the upper shelf is 33 inches; from floor to top of lower shelf is 6 inches, and from top of lower to top of upper, 27 inches. The shelves are 24 inches in diameter. Around the edge of the upper shelf are 36 notches in which the handles of the Axes fit, the Axes resting on the lower shelf, the weight of the bit of the Axe being sufficient to keep the handles in place. Around the upper shelf, 6 inches from the edge, there are 18 pins shaped like the eye of the Axe, on which the unhandled Axes are placed, they being sufficiently far apart to admit an Axe between them, thus making room for 18 more Axes, and making three dozen in all. The small urn or bowl is for Axe Stones and Wedges. It stands 11 inches from the top and is 9 inches across the top. The top shelf is supported by six boards arranged at equal distance around the circle. The whole is upon casters, which allows the stand to be moved around the store at the pleasure of the dealer.



A Convenient Axe Stand.

The trade will recognize the convenience of this Axe Stand, in view of its simplicity and the comparatively small space occupied in displaying an extensive line of goods, with the further advantage that it allows every Axe to be examined without disturbing any of the others.

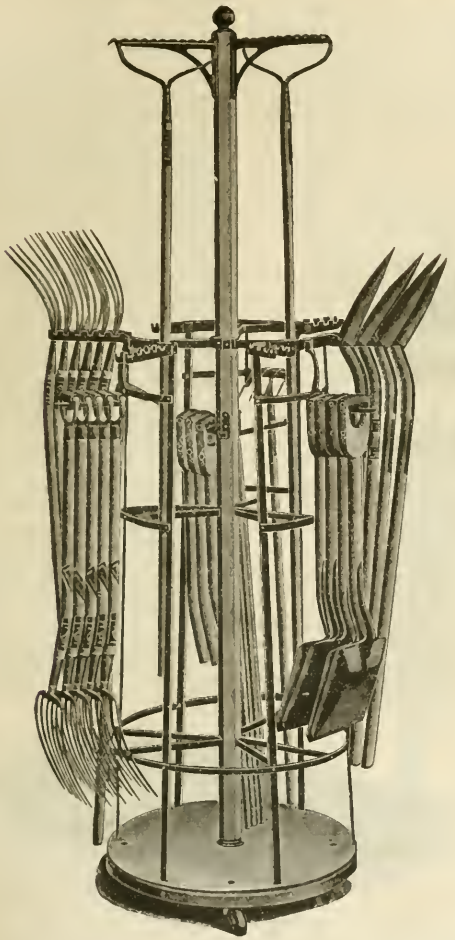
Revolving Show Stand.

The accompanying illustration of a revolving Show Stand is reproduced from the London *Ironmongry*, and consists of a block of wood about 18 inches long and 4 inches square, covered with a piece of virgin cork. A piece of cork that will just fit around the block in its natural curl without cutting is the best, and is secured by fixing a 6-inch circular block at each end. The articles to be displayed are attached in picturesque disorder, not being crowded lest they become confusing to the eye. Knives, Forks, Scissors, Corkscrews, Ice Picks and other articles can be securely attached by the points, so as to stand out prominently from the cork, forming an attractive display. This is made to revolve by a roasting jack concealed in the cork above the stand, the constant movement and the glitter from the polished surface of the goods in the sun or gaslight arresting the attention of passers-by, proving, it is said, a wonderful and constant source of interest. We suggest that an electric motor or other power could readily be substituted for the roasting jack by those desiring to utilize this idea for displaying this class of goods.

Revolving Show Stand.

Herrick's Agricultural Tool Rack No. 2.

F. A. Herrick & Co., 228 Second street, Jackson, Mich., have put on the market a



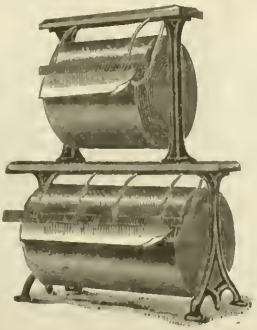
Herrick's Agricultural Tool Rack No. 2.

tool rack, as illustrated herewith, reduced in size but constructed upon the same principle as their No. 1 rack. The No. 2 is designed especially for use where floor space is limited, the platform being but 30 inches in diameter, whereas the platform of the large rack is 4 feet across. The No. 2 rack holds 120 tools and handles, and when desired will be furnished to revolve so that in a crowded store it may be rolled in some corner out of the way and revolved to get at the tools needed, thus economizing considerable room. Testimonials from merchants having used the large rack indicate that but about one quarter the space is required for the accommodation of the same number of tools as with other racks and that sales on such goods are largely increased.

It is reported that as a result of the Old Colony deal the consolidated road has placed an order for thirty-five new locomotives with the Rhode Island Locomotive Works of Providence.

Economic Hopking Roll Paper Cutter.

The roll paper cutter herewith illustrated, put upon the market by the American Roll Paper Company, St. Louis, Mo. has the original Hopking knife and an improved automatic finger for raising the sheet of paper. Thus the paper is always in a position to be readily grasped for tearing it off. The cutters are well finished in japan and hardwood, and are made in all sizes from 6 to 36 inches. They are made in pyramids of every kind or in single rolls.



Roll Paper Cutter.

Decorated Imperial Ironware.

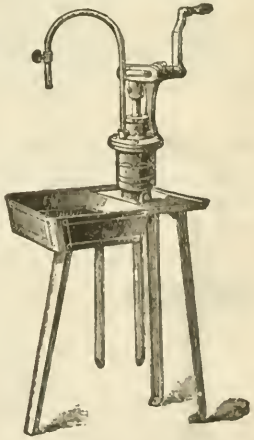
St. Louis Stamping Company, St. Louis, Mo., are putting a line of these goods on the market, an illustration of which is herewith given. The tea pot shown is of decoration K; coffee pots are also made in the same style, the line being known as

Decorated Imperial Ironware.

the Acme. The goods have bright tin lids, wooden handles, and are finished both inside and outside in ironware. The goods are designed to supply the demand for a cheaper and more popular grade of goods than those finished in nickel plate.

Self-Measuring Pump.

The Bevan Mfg. Company, through Morgan & Cornell, 42 Hudson street, New York, are introducing an improved pump, as here illustrated. This is designated



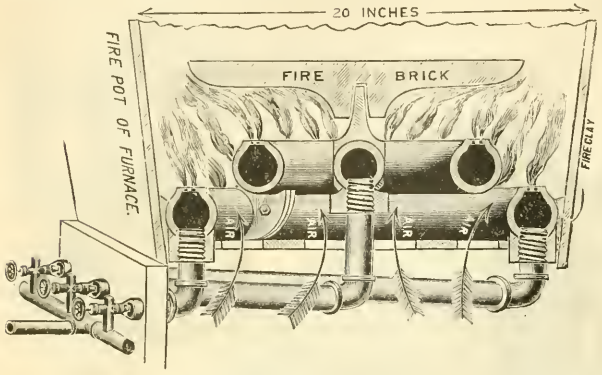
Bevan Self-Measuring Pump.

as a self-measuring liquid conveyor, intended largely for handling kerosene, benzine, turpentine, &c., dispensing with the use of tanks, funnels and measures. The advantages claimed by the makers for this over the old method are as follows: Barrels or cans of oil can be stored in the cellar or outbuilding and connected with the pump by means of two pipes, one of which conveys the oil to the pump and the other

returns the drip. One full turn of the crank measures exactly one-half pint, thus allowing the material to pass directly into the purchaser's can. The pump is hermetically sealed, avoiding disagreeable odors, occupies but 1 square foot of floor space and can be placed where most convenient. Emphasis is laid on the reduction of fire risks to a minimum by its use.

The Duplex Ring Burner.

E. C. Merrill, 168 Second avenue, Pittsburgh, Pa., has brought out an improved form of his Duplex Ring burner, designed

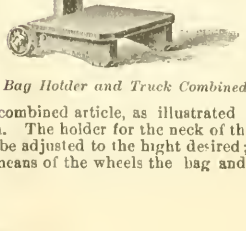


The Duplex Ring Burner.

especially for cast-iron fire pots from 16 to 20 inches in diameter. We understand that the burner has given excellent results in operation, and the manufacturer is well pleased with its record as a gas saver, making reference to one case where it was used with 50 feet of gas in a five room dwelling. The principle embodied in the Duplex is to exclude the draft on the side of the fire pot and take the necessary supply above the gas flame. This, the manufacturer says, gives a mixture by gravity, and causes the flame to travel close to the side of the fire pot. This burner has been adopted successfully in hot air furnaces, power boilers, and steam and hot-water heating boilers. In the latter case, it has been used with the hot-air thermostat furnished by the Merrill Thermo Valve Company.

Bag Holder and Truck Combined.

Ames Plow Company, Boston, and 53 Beekman street, New York, are offering

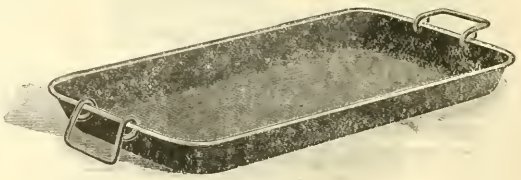


Bag Holder and Truck Combined.

the combined article, as illustrated herewith. The holder for the neck of the bag can be adjusted to the hight desired; and by means of the wheels the bag and contents can be trucked onto the scales and off again, or to any portion of the building, without handling it. The device is especially designed for warehouses where grain or other matter is handled in bags.

Pressed-Steel Pans.

The Kilbourne & Jacobs Mfg. Company, Columbus, Ohio, are manufacturing these pans, as shown herewith. The pan is stamped from one sheet of steel, and the flange or top edge of the pan is turned over a $\frac{5}{16}$-inch steel rod, stiffening and strengthening it and giving a smooth finish. The handles are of $\frac{5}{16}$ inch round iron, and drop down against the sides of the pan when not in use. The pans are designed for use in bolt, rivet and screw factories, machine shops, &c., under lathes and kindred machinery, to catch the turnings, trimmings and borings from the tools. The smaller sizes are adapted to handling



Pressed-Steel Pan.

small castings, bolts, rivets, &c., in process of manufacture, from one machine to another. The point is made that these pans are much more desirable and convenient than wooden boxes, or sheet iron trays bent up and riveted, for such purposes.

MEMORANDA.

The recently organized firm of Cavanagh & Thompson, dealers in Cordage, Brushes, Brooms, Earthenware, Glassware, Woodenware and other lines of house-furnishing goods are now fairly established in their quarters at the intersection of Reade and Hudson streets, New York, where they are always pleased to welcome their friends. They refer to business as satisfactory and promising well.

John M. Waddel, Greenfield, Ohio, issues a circular in which he announces his withdrawal from the John M. Waddel Mfg. Company as secretary and manager, and states that he is now equipping a new manufactory with the latest improved machinery, to be known as the Waddel Wooden Ware Works. It is expected that the new firm will be ready to market its goods not later than April 1. A full and complete line of Cash Registers, Money Drawers, Coffee and Spice Mills, Animal Traps, Toys and novelties will be manufactured. It is stated that new ideas and artistic designs will be introduced in Coffee Mills, and that all goods, in fact, will be made from patterns but recently designed.

United States Gutta Percha Paint Company, Providence, R. I., are putting on the market a paint designated by the letters A. B. C., which represent the full title, which is, Architects', Builders' and Consumers' Prepared Paint. This paint is put up in gallon, half gallon, quart, pint and half pint packages, which are labeled handsomely. This line is specially designed for the Hardware trade, and makes very attractive shelf stock. The manufacturers are sending out sample cards to the trade, which may be had on application.

An entertainment, hop and reunion will be given by the Philadelphia Hardware Association on Thursday evening, February 23, at 8 o'clock, at Young Maennerchor Hall, corner Sixth and Vine streets, Philadelphia. A very entertaining programme, including accomplished talent, has been prepared, and several well-known speakers will make addresses. In addition an excellent orchestra has been engaged to discourse music. The association are hoping for a large and representative attendance of the Hardware interests of the city. The entertainment is in charge of the following committee: H. L. Stortz, E. H. Shannon, L. C. Glading and S. S. Raser.

S. O. Cummins of Bellaire, Ohio, advises us that he is putting in the show window of his Hardware store a plate-glass front, 10 x 15 feet in dimensions, with mirrors at sides. Mr. Cummins refers to this as the largest plate-glass front in the city.

Arrangements for the hardware dinner next Tuesday evening are about completed. We are advised by the committee that the demand for tickets has exceeded the supply, and a good many persons, many of them connected with leading houses, have been unable to obtain tickets. The success of the dinner in point of numbers is thus assured, and everything would seem to indicate that it will be a thoroughly enjoyable and representativegathering.

The whale fisheries last year as a whole were successful. The catch of whales by the combined fleet in the Arctic Sea and South Atlantic was 214, against 212 in 1891. The number of vessels engaged in the business January 1, 1893, was 95, with a tonnage of 21,165, against 92, with a tonnage of 20 845, January 1, 1892, while in 1860 the fleet consisted of 569 vessels, with a tonnage of 176,848.

A bill to prevent tramp steamers transporting merchandise from one American port to another, by making a triangular voyage to a foreign port, has passed the United States Senate.

A firm of butchers in New York, with $5,000,000 capital, are establishing large slaughter houses in Kansas City, in competition with firms in Chicago.

The Tin Petition.

In view of the fact that a duty of 4 cents per pound is to be imposed on pig tin after July 1 of this year, a petition is being circulated by T. J. Pope's Sons & Co. of 292 Pearl street, New York, which is to be presented to Congress, asking that that section of the McKinley bill be repealed. It is claimed that it is now evident that tin mining in this country has not been a success and that the production of pig tin could not reach 5,000 tons per annum during the next two years, as would be necessary under the McKinley bill; fear also being entertained that the existiog state of affairs will lead to disastrous speculative operations, consumers of tin in all forms are being asked to sign the following petition:

Whereas, By the law passed in October, 1890, and known as the McKinley bill, pig tin is subject to a duty of 4 cents per pound, to take effect on and after July 1, 1893, with a proviso that unless the production of pig tin in the United States is shown to be 5000 tons per annum, during the ensuing two years, the duty should thereafter be abrogated, and, whereas, from competent and expert testimony it is already known that the home production of the article cannot, in all human probability, amount to anything approaching the quantity named of 5000 tons per annum, the undersigned, your humble petitioners, respectfully represent that it is extremely unjust to the people of the United States, and more particularly to those directly interested, as consumers of an article of prime necessity to the industries and arts, that the said tax should now be imposed. Pig tin is a raw material, practically unproduced in the United States, and has been for many years on the free list.

The importations now reach an aggregate of about 21,000 tons per annum, the duty on which at 4 cents per pound will amount to nearly $2,000,000.

We further respectfully represent that the imposition of a tariff upon pig tin is directly opposed to the tin-plate industry, which it is so desirable to introduce and foster in this country, and toward which commendable progress has already been made.

In view therefore of the facts above stated, we humbly petition that the law, so far as it relates to the imposition of a duty on pig tin, may be promptly repealed or its operation suspended.

The petition has not yet been issued to the New York trade, but in the quarters where it has been circulated it has met with a considerable response. The signers to date are as follows:

Michigan Brass & Iron Company, iron and brass founders, Detroit, Mich.
Western Electric Company, electrical goods, Chicago, Ill.
John T. Noyes Mfg. Company, mill machinery, Buffalo, N. Y.
J. M. Batchelor, financial editorial writer, Brooklyn, N. Y.
Hook & Hastings, church organ builders, Boston, Mass.
Meneely & Co., bell founders, West Troy, N. Y.
J. Regester & Sons, bells and brass work, Baltimore, Md.
Meriden Britannia Company, silver-plated ware, Meriden, Conn.
Granular Metal Company, Boston, Mass.
Elbel & Co., saddlery hardware, Canton, Ohio.
Westinghouse Machine Company, steam engines, Pittsburgh, Pa.
C. Van Norden & Co., solder makers, Boston, Mass.
Standard Stamping Company, tin ware, St. Louis, Mo.
Cincinnati Lead Pipe & Sheet Lead Works, Cincinnati, Ohio.
East Hampton, Bell Company, bells, East Hampton, Conn.
Starr Bros. Bell Company, bells, East Hampton, Conn.
Gong Bell Mfg. Company, bells, East Hampton, Conn.
L. M. Rumsey Mfg. Company, manufacturers and metal dealers, St. Louis, Mo.
Covert Mfg. Company, hardware specialties, saddlery, West Troy, N. Y.
E. F. Kirwan Mfg. Company, tinware, Baltimore, Md.
Geo. R. Meneely & Son, brass founders, West Troy, N. Y.
R. Tynes Smith Can Company, tin goods, Baltimore, Md.
Boyden Brake Company, car brakes, Baltimore, Md.
Troy Nickel Works, stove trimmings, Troy, N. Y.
Samuel Pierce, metal organ pipe manufacturer, Reading, Mass.
Chas. G. Summers & Co., can makers and packers, Baltimore, Md.
Wm. Litchfield, copper and brass founder, Charlestown, Mass.
John L. Finney & Bros., vegetable and fruit packers, Aberdeen, Md.
R. Emery, can packer, Taylor P. O., Md.
Harry Lambert, packer of canned goods, Salem, N. J.
Great Western Smelting & Refining Company, Chicago, Ill.
Wm. Powell Company, brass founders, Cincinnati, Ohio.
F. H. Lawson & Co., dealers in tin plate and metals, Cincinnati, Ohio.
Fait & Slagle Company, oyster and fruit packers and manufacturers of tinware, Baltimore, Md.
J. F. Brady & Co., packers of canned goods, Bridgeton, N. J.
Wm. King & Son, church-organ builders, Elmira, N. Y.
H. W. Colter Canning Company, fruit canners and can makers, Mount Washington, Ohio.
H. F. Stern, canner of fruits and vegetables, Zanesville, Ohio.
Excelsior Brass Works, brass goods, Duquesne, Iowa.
A. F. Brown, packer, Havre de Grace, Md.
F. M. Anderson, canner, Keokuk, Iowa.
Baltimore Chemical Company, manufacturers of chemicals, Baltimore, Md.
P. O. Klinefelter, tinware, roofing, &c., New Freedom, Pa.
Sidney Shepard & Co., itware manufacturers, Buffalo, N. Y.
Enterprise Mfg. Company, hrdware, Philadelphia, Pa.
Automatic Switch Company, Baltimore, Md.

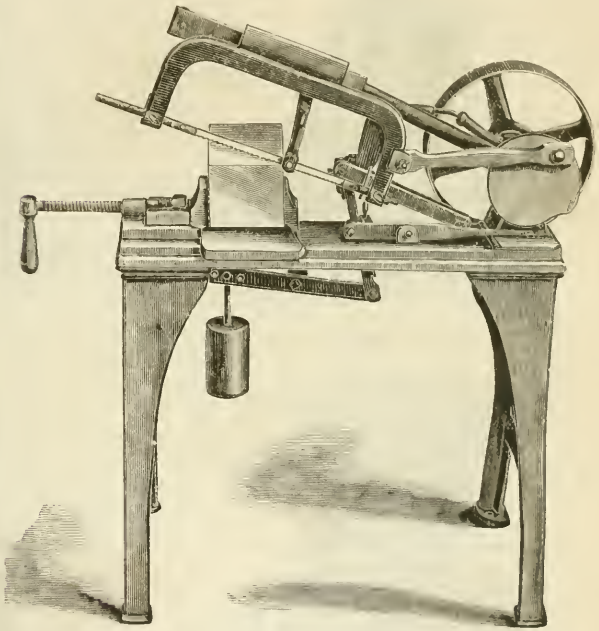
It will probably be two or three weeks more before the canvass will be completed and the petition in proper shape for presentation to Coogress.

The new Waldorf Hotel on Fifth avenue and Thirty-third street cost over $5,000,000, and the building is as completely fire-proof as it can be made. At each end of the deep building a fire-proof well, lined with fire brick, runs from roof to foundation, inclosing a steel stairway. The greater part of the ironwork was furnished by the Cornells.

The Leader Sawing Machine.

The Leader sawing machine, recently put on the market by the Frasse Company of 90 Park Row, New York, is intended for cutting iron or brass bar or tubing of any shape or size up to 5 inches in diameter. The machine is provided with an automatic tension which permits of adjustment for metals of various densities, this being accomplished by setting the weight forward or backward on the lever to suit the class of work operated upon.

The adjustment of the weight also controls the blade for rapidity of cut, as when the frame has advanced and made a cut it is lifted slightly, freeing the blade during the return stroke, thus preventing the teeth from dragging; upon completion of the back stroke the frame descends and is ready to make a new cut. It will be readily seen that the life of the blade is lengthened by this construction. A pivoted vise similar in design to a planer chuck is employed to hold the work, thus enabling the user to cut off pieces at any angle. A table-like projection is added to the bed below the vise to prevent a partly detached piece from dropping to the floor. The saw clamps, adjustable for a blade up to 14 inches in length, are so arranged that the straight running of the blade is insured. The machine is provided with a gauge for regulating the length of the pieces to be cut and also with an extra saw guide, which may be attached to the frame guide by a thumb screw. This is of benefit when very thin sections are to be cut off, but is not necessary for ordinary work, as the blade runs well enough without it. The shaft bearing is bushed; consequently the resultant wear comes on the bushing and not on the bearing, and as it is bored and turned to a standard size, in case of wear it may be replaced easily.



THE LEADER SAWING MACHINE.

The naval docks at Brooklyn and Puget Sound are to be lengthened to 650 feet.

Some New Gem Furnaces.

The Burgess Soldering Furnace Company, Columbus, Ohio, will place upon the market about March 1 a new combination furnace, which they call the Gem No. 6. General views of the furnace are shown in the accompanying illustrations. Fig. 1 is a furnace for tinners' use, and it will be seen that the opening in the hood of the furnace will accommodate large coppers. The plate on which the coppers rest is of cast iron, deflected with projections forming flues for conducting the heat underneath it. The sides are also provided with flue plates to protect the bolts and also to take the heat from rear to front of hood, and to prevent it from burning the handles of the coppers. It is furthermore provided with a removable cast-iron top or lid which will not fall off, but which may be removed to accommodate the ordinary size melting pot. The tinners' furnace is said to work out of doors in all kinds of weather. Fig. 2 shows a furnace for plumbers' use, which, it is said, will heat coppers and melt metal at the same time. The slot burner is cylindrical and furnishes a flame 4 inches long on each side. The burner is of cast iron, and there is no gauze or perforated tin used in its construction. It is recessed at front and back for the purpose, it is pointed out, of preventing damage if roughly used. It is further mentioned that the construction and shape are such that solder from the coppers cannot fall into the perforations, and at the same time that heat is distributed the full length of the coppers. This furnace, it is claimed, will heat 4-pound coppers in two minutes, to the forging heat in five minutes and heavier coppers in slightly longer time. The reservoir is described as pneumatic and fire proof, and cannot be filled while the burner is lighted. It is made of IXXXX tinned steel or copper, and suspended under a heavy steel base to protect it from injury. An electrical furnace for lineman's use is illustrated in Fig. 3. These furnaces, it will be noticed, flare at the base sufficiently to protect the air and oil faucets. They are provided with sliding cut-offs and drip cups, and are furnished with a bail, making them portable. The superior quality of the patent bulb, which is made of black rubber, is alluded to. It is also mentioned that the air, oil and regulating faucets are all provided with stuffing nuts to prevent leakage. Alaska handles on the regulating faucets insure their being always cool. Fig. 4 shows a furnace intended for printers' use. It is also referred to as adapted to the wants of electricians, tinners, plumbers, dentists and pattern makers.

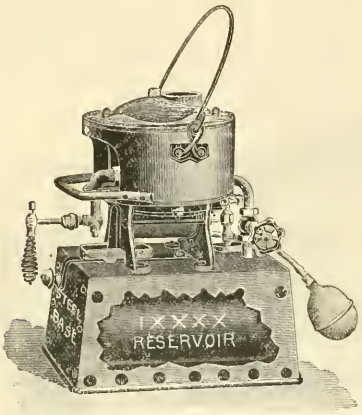


Fig. 1.—Tinner's Furnace.

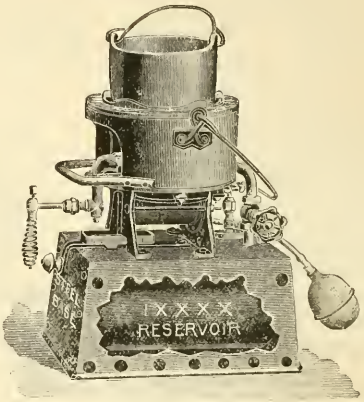

Fig. 2.—Plumber's Furnace.

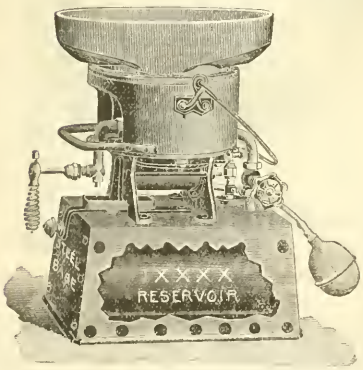

Fig. 3.—Lineman's Furnace.

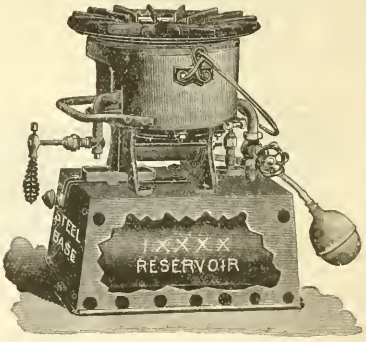

Fig. 4.—Printer's Furnace.

SOME NEW GEM FURNACES.

Australian public finances make a poor showing when analyzed by intelligent observers in Melbourne. Within a few years half a dozen banks have gone down, entailing losses exceeding £5,000,000 sterling, and although enormous sums have been borrowed by the several governments only a small proportion has gone into works of general utility, so that now the principal difficulty is in obtaining money to settle the interest account. It is stated that altogether the colonies have borrowed in the last four years $185,000,000. A correspondent of the London *Economist* writes: "Several of the governments have large deficits yet to meet. The New South Wales Government had used up all available resources, trust funds, savings bank funds, &c., at the time it resolved to try a local loan, and had close upon £3,000,000 to find. The Victorian Government, while showing by bookkeeping entries that it still has a balance available for fresh public works, is steadily exhausting its cash resources, and must by June next be at the point of begging the banks for temporary assistance unless it can float new loans. The outlook is a serious revenue deficit." In Melbourne the depression is without relief.

An enormous freight house for the Pennsylvania Railroad Company will be added to the plant already owned by that corporation on the Hudson River front above Thirty-seventh street. The land just bought cost $250,000.

STOVE TRADE NOTES.

A Phase of the Stove Trade.

A stove manufacturer, whose works are located in one of the largest iron-producing States of the country, relates an interesting experience, which has probably been duplicated, in some particular at least, by stove makers all over the country. The circumstance is described and presented to our readers in order that others engaged in the business may express their views concerning it, especially with regard to the best methods of treating cases of this kind. The manufacturer writes as follows: "A dealer in a distant State orders through our salesmen, with other goods, a large heater of our manufacture, and which is well known for excellent working qualities. He settles for all the goods except the heater, and writes us to the effect that it has been sold and that its working does not give satisfaction. We must either give him instruction which will make it work or he will return the stove. Now, we know the stove in question so well that we understand in a moment that it is in the hands of one of those woefully ignorant persons who would not know how to operate a Dutch bake oven, and who would make us pay for his ignorance if we would allow him to do so. We accordingly write to the dealer, giving him full directions as to the use of dampers, &c., at the same time hinting that he is expected to know all this. We told him that if these directions are observed and the stove still refuses to work we will have to take it back. Upon its return, however, we shall put it up just as received and test it ourselves. If we find it to be all right we will expect him to stand freight charges and the difference between a new and a second-hand stove. The dealer is evidently sure that the stove is a failure, for it comes back to us without any comment from him. We carry out our plan of testing the thing and find that it works perfectly. Accordingly, we write our friend a letter advising him as to what we have done and giving him the information that the loss shall certainly be made up from his pocket if we are at all able to bring this about. We may never again sell this man, but our brother in the business will probably escape having perfect goods returned through a whim of the dealer or ignorance of his customer."

London Fogs and American Stoves.

We have recently referred in these columns to the effort being made by the Reading Coal & Iron Company to introduce anthracite coal into the European markets, and the opportunity which seemed open for creating simultaneously a demand for American stoves in which to burn the fuel. In connection with this subject, it appears, from an account published in *Coal and Iron* of London, that, driven to desperation by the ravages of the fog fiend, a strong association has just been formed, in that city, under the title of the "Anthracite Association for the Promotion of the Use of Anthracite Smokeless Coal." The patrons and committee of the association include a number of influential and well known names in the commercial, industrial, political and scientific worlds.

The increasing prevalence of fogs in London is so unquestionably due to the immense volume of smoke thrown into the atmosphere by the almost universal use of bituminous coal in that city that the association, being impressed with this fact, are determined to use every effort to introduce the adoption of smokeless coal as the only means for abating the nuisance. And we learn that their efforts are likely to meet with great success. Already in many public institutions, hotels, clubs, railway stations and private residences the use of anthracite in place of bituminous coal has been adopted with good result. Scientists recommend this change as the only solution to the London fog problem, and it is believed that the more intelligent of London householders will be induced to give the association practical support by acting on their recommendations. The article from which we gain our information in regard to the Anthracite Association strongly recommends the use of anthracite for its freedom from smoke, cleanliness, absence of waste and dust, as well as for its economy, and states that "when treated intelligently—*that is to say, burnt in a grate or stove properly adapted for its consumption*—it has much to recommend it, especially in a hygienic sense," and further, in conclusion, it observes as follows: "Enough has been said to show that, *with the use of proper appliances, there is a great future in store for anthracite coal;* but much will, of course, depend upon the vigor and energy with which its claims are pushed forward by those who are interested in its adoption as a specific against the evils with which the London fog fiend can now, with apparent impunity, afflict us." The italics are ours.

Chimneys and Drafts in Operating Stoves.

At the last convention of the National Association of Stove Manufacturers, provision was made for the preparation of two circulars, one containing directions for setting up and operating stoves, and the other describing the possible and probable difficulties connected with chimneys and their flues, to be furnished any manufacturer who might choose to order them. It was stated in the convention that these sheets would give a variety of suggestions and ideas which stove manufacturers could probably use to advantage, for they could be sent with orders from dealers and thus offer instructions regarding the setting and operation of stoves in a way which would not prove other than satisfactory. Secretary Thomas has just issued copies of circulars of the character named and we have pleasure in presenting them herewith. The first is entitled "Directions for Operating Stoves," and presents a number of suggestions which the trade cannot fail to appreciate. It reads as follows:

To secure good operation in cook stoves and ranges, see:

1. That the flue stopper is in its place.

2. That the chimney is clear and has a good draft at pipe hole. Many chimneys are made too low and draw better when a smoke stack is put on them.

3. That the pipe fits closely on the stove and in the chimney. No air should go outside of the pipe.

4. That the pipe does not go too far in the chimney.

5. That no ashes from chimney get into the end of the pipe.

6. Avoid having the pipe telescope at the elbow. If you have all these parts properly adjusted and well arranged, open the direct-draft damper and see if you can get a good fire in the stove, together with a strong draft. If the stove will not burn well then, the trouble is not in the stove, but above it.

If the fire burns well on the above direct draft close the oven damper, then if it will not heat the oven and bake well please examine the flues and damper, and see:

1. That all the flues are open and clear so that smoke can freely pass through them. In cleaning flues many do not clean all the flues, and frequently push soot and ashes into back corners, and in that way stop them up.

2. Examine all the dampers in the flues and see that they open and close tightly and do not get out of place.

3. Be sure that you know how they operate, so they may not be open when you think they are closed.

If you are trying a stove without a hot-water reservoir and have everything in good order, as heretofore described, it cannot possibly fail in operation if you close the direct-draft damper and throw all the heat around the oven. Time should be given to get the oven hot before trying to bake.

If you have a stove with a reservoir be sure that the damper (if one is in the stove) to force the heat under the reservoir is closed, so that all the heat must go around the oven. Many reservoir stoves have two dampers, and in that case both should be closed.

We have known many persons who have tried to use such stoves with that damper under the reservoir open when they thought it was closed. On that account the oven heated too slow, but worked fast enough when they closed the damper.

It is possible that the draft of the chimney is so strong as to carry the heat so rapidly round the oven as not to be absorbed by the plates, and the oven fails to heat sufficiently from that cause. A damper in the pipe will relieve this.

The second circular is made up of extracts from various publications respecting chimney, drafts, &c., and reads as follows:

No stove has what is called a draft; it is the chimney (or its equivalent) that produces the draft. The taller the chimney the stronger the draft.

A stove can no more operate without a chimney than a steam engine can operate without a boiler.

If a stove fail to give satisfaction it is because of having a bad chimney or being improperly set up.

If a stove fail to operate, the chimney must be looked to for a remedy.

There are more bad chimneys than good ones.

Dealers should always know the character and condition of the chimney before they put up a stove, and they ought to know that a stove cannot operate without a good chimney, reasonable fuel and being properly set up.

As the maker of stoves builds neither the house nor the chimney, he cannot be held responsible for the operation of the stove, as a stove cannot operate of itself; it must have a chimney, it must have good fuel and it must be properly set up to do good work, otherwise it will fail, and the responsibity must be with the chimney or with its being improperly set up, and not with the stove.

The dealer often forgets that the things that prevent the stove from working are located between the pipe collar of the stove and top of the chimney, if the stove has met with no accident in the transit. It does not seem to occur to him that the pipe and chimney are to do the drawing. As well say the buggy balks when the horse refuses to go as that a stove can't draw.

Even in this day of almost perfection in cooking and heating stoves there is probably not one stove in the market but what here and there is said "not to work," and the twin expression is, "What shall we do with it?"

It is absurd for a man who can see the chimney and the stove set up to write to a manufacturer who cannot see either and ask why

the pipe and chimney will not draw or "work."

There is no manufacturer now making stoves who turns out goods that will not work.

Retail dealers in stoves and ranges, and those compelled to use poorly constructed or decayed chimneys will do well to read sufficiently to enable them to ascertain what the matter is when a well-constructed range or stove fails to operate as it should.

We illustrate a few of the causes why the stove is condemned when the fault is solely in the chimney.

A. Constructing a chimney by extending the flue downward to the floor, and in many cases into the cellar, creates a place for the accumulation of soot, ashes, &c., so as to save the expense of cleaning the flue, then the cold air below the pipe-hole chills the entire column of air in the chimney; it is therefore heavy and impedes the ascent of the smoke. The remedy is to either fill the flue with cement to within 6 inches below the pipe hole, or cut off the flue with a sheet-iron plate, the plate to be covered with several inches of cement, so as to make it air-tight. The result will be to apply the heat at the base of the flue, and a good draft obtained.

B. Often, complaints are made that the cook stove will not operate, although the pipe was carefully fitted into a chimney that has a good draft, and which has been in use for many years. Investigation proves that the stove is attached to a chimney whose base contains a very large old-fashioned open fire place. The remedy for this is the same as the preceding.

C. The chimney of the kitchen may be much lower than the main part of the house. The wind blowing over the house falls like water over a dam, sometimes almost perpendicularly on the top of the chimney, thus it beats down the smoke contained therein. The remedy is to build up the chimney, or add a smoke stack to equal the hight of the main building.

D. A building or a large tree may be near to and higher than the top of the chimney, so that the wind passing over them would blow down on the chimney.

E. When there is more than one opening in a chimney, a great variety of complications may affect the draft, so see that all the openings into the flue, no matter of what kind, except-ing the one you are going to use, are securely closed.

F. When two or more stoves are connected with one single chimney the combination is so variable that it is difficult to cover all such cases by specific directions. Common sense, directed by observation, must be used.

G. A new or green chimney will never have a perfect draft. It will not draw perfectly until it is thoroughly dried, which sometimes requires two to four weeks' time.

H. In building a chimney, a little mortar may be dropped from time to time and lodge out of sight, so as to partially close the chimney. A heavy weight may be let down by a rope and worked against the inside of the flue to force an operation.

I. In an old chimney the mortar may have crumbled from between the bricks so that it leaks air and spoils the draft.

All the air that passes through the chimney should first pass through the fire, unless used to check the draft.

At the close of the circular are four diagrams showing the manner in which chimneys should be extended above the roof of a building in order to secure a good draft, and also showing the construction which furnishes a very poor draft for a stove.

The Central Oilgas Stove Company

send us a copy of a new catalogue which they have just issued to the trade. It consists of 96 pages of letterpress, profusely illustrated and bound in heavy paper covers, carrying a side title which embraces the name and address of the company and an indication of the line of goods manufactured. The opening pages give the addresses of the various offices and salesrooms of the company, the terms and discounts, a comprehensive index, a bird's-eye view of the works at Florence, Gardner and Jackson, the division of territory showing the section covered by each office, and a statement to the trade relative to the goods produced. Attention is first invited to lamp stoves, of which a varied assortment is presented, including the American, Champion, Tom Thumb, Fairy Queen, Florence, Columbia, Monarch, Volunteer, Globe, Gypsy and the Sun. In this connection the makers state that they guarantee all their lamp stoves not to leak. Following these is a description of the oil-gas cook stove which was first introduced to the trade late in the season of 1892. The merits of this stove are set forth by means of ample descriptive letterpress, in which it is stated that the stove vaporizes and burns common kerosene or any of the refined products of petroleum, that the burner, which has no wick, has been enlarged, and the heating capacity increased fully 50 per cent. The Oilgas cook stoves for 1893 are made in four distinct combinations, known as the Florence, American, Crown and Champion. Numerous testimonials are also presented from those who have used these goods. Next in order the Oilgas vaporizing cook stoves are illustrated in numerous styles and sizes. The various features are carefully pointed out and much interesting information to the dealer is presented. A long line of gas cook stoves is shown, these having been improved for this season, especially the cabinet ranges. A new stove is the Cone. There are also many styles of sheet metal and glass reservoir oil cooks. The latter portion of the catalogue is devoted to cast iron oil cooks, ovens for lamp stoves, extension tops, sad-iron heaters, furnishings for oil-gas and vaporizing stoves, circular burner oil heaters; an illustrated description of the American oil heater, the Chicago and Florence heaters, the Globe circular burner floor lamp heater, the Grand and the Oilgas fireplace heaters. There is also shown a number of flat wick oil stoves with radiators as well as gas-heating stoves. The catalogue is of a character likely to prove interesting and valuable to stove dealers, especially to those handling goods of the description named.

Bower-Barffing Stove Castings.

A correspondent, writing from one of the Western States, raises the question, why some enterprising stove manufacturer does not initiate the use of iron castings which have been through the Bower-Barffing process on all the iron work that is now nickel plated for stove trimmings. The idea, he says, was suggested by the receipt of a sample cook stove, having the nickel work seriously rusted, probably by the action of frost, and the patterns of which had been in use but two or three months.

"As I understand it," he writes, "this process is cheap enough, so that a large share of the hollow ware in France is made by it, and if the French can afford to use it for stove hollow ware, it certainly ought not to be too high for Americans to use on the iron that they nickel plate. It is possible there may be some mechanical reason why this cannot be used. It might not hold nickel, but if there is no such reason, any house that could send its men out in the fall, assuring their customers that nothing could rust their nickel plating, would have more business than they would know how to handle."

We referred the matter mentioned by our correspondent to Secretary D. M. Thomas, of the National Association of Stove Manufacturers, and who is also president of the Bower Barff Rustless Iron Company of this city. In discussing the matter he states that the Bower-Barffing of stove ornaments previous to nickeling is not feasible. The plating would not always be perfectly adherent and the polished surface would be measurably injured by the treatment, while the appearance would not be altogether satisfactory. It is possible to Bower-Barff stoves and so prevent them from rusting, but as the process requires the iron to be made red hot, the plates would be liable to warp and twist to such an extent that difficulty in mounting would be experienced, while the cost would be largely increased. Sample stoves might be treated with advantage, but, in the opinion of Mr. Thomas, the process is not commercially applicable to stoves. He states, in this connection, that he has under consideration a new method of depositing metals and that he may shortly offer stove manufacturers a new and superior style of ornamentation.

The Enterprise Stove Company

of Vincennes, Ind., send us a copy of their catalogue for 1893. Its 78 pages are replete with matter of interest to the wide-awake stove dealer and the goods are illustrated in a manner to show them to the best advantage. The covers of the book are of colored paper, the front carrying a side title that is typographical in character. One of the first things to catch the eye of the reader is the injunction of the company with regard to ordering castings. It is to always give the name, number and date of the stove. The goods shown includes the Home Star for burning coal or wood and embodying the latest improvements, also the Home Star wood range, having large fire box, double fire bottom and fire box draft plate to force the draft under and through the fire instead of over it, as is often the case. These goods are shown in a variety of styles and are made in a number of sizes. The North Star is a cheap first-class wood range, having four boiler holes, and is made in three sizes.

The Home Star is a coal and wood cook, having draw hearth, patent long cut center, sectional fire back and dumping and shaking grate. It is made in four sizes and the usual modifications. The Guiding Star is another attractive member of this general class, as are also the Rising Star, the Home Star, the North Star and the Princess. Among the heating stoves which occupy the latter portion of the catalogue we notice the Silver Star, a very attractive base heater for burning wood. It has shaking and draw-center grate and the end feed door is attached to the damper in such a way that the stove operates with direct draft as long as the feed door remains open. The Bright Star Todd is a handsome construction, having extra heavy fire linings, which can be taken out and replaced without dismounting the stove. There are also shown several round-base burners, oak, Franklin, cottage parlor, laundry, box and cannon stoves, together with a list of stove hollow ware.

ODD PLATES.

The Peninsular Stove Company of Detroit send us a serviceable calendar for the new year consisting of a substantial leather-covered frame, having a solid back and measuring 5¼ x 4 inches. It is so made that six cards, each of which carries a calendar for two months, one being upon either side, can be slipped into the frame from the top, and as the month passes the second card can be drawn out and placed in front of the one previously exposed to view. Across the top of the frame is the name of the company, at the bottom are the names of the cities in which their works and offices are located, while at the sides is an indication of the line of goods manufactured. The back of the card frame is arranged as an easel, and when the flap serving as a support is raised there are exposed to view calendars for 1893 and 1894. There is also a loop for hanging the device upon the wall if preferred.

The Raymond & Campbell Mfg. Company of Middletown, Pa., have issued a notice under date of February 10, to the effect that their branch store at 45 North Second street, Philadelphia, has been discontinued. They notify their customers to send all orders and correspondence to Middletown, Pa.

We have received a copy of a very neat catalogue of something over 60 pages, issued by the Schneider & Trenkamp Company of Cleveland, Ohio, bearing the im-

print of William J. H. Gluck, who is agent for the company's goods in Baltimore, Md. The volume is carefully arranged, neatly printed and covers a great variety of gasoline goods made under the name "Reliable." Ample descriptive letter-press is presented, together with dimensions, prices, weights and other information of value in this connection.

Among the recent incorporations at Albany, N. Y., may be mentioned the McDonald Stove Company of Watervliet, N. Y., with a capital stock of $125,000.

William M. Gobeille, Main and Center streets, Cleveland, Ohio, issues a postal-card notice to the trade relative to the line of work he is prepared to execute. The matter is presented in verse and is entitled, "The Last Words of a Grate Pattern Man." The heading is a *fac-simile* of a portion of what we assume to be the letter head employed by Mr. Gobeille in his correspondence.

The plants of the Somersworth Machine Company at Dover and Salmon Falls, N. H., are the subject of a long article which appears in the New Hampshire *Republican* of February 10. It states that the corporation was started in 1848 by a board of directors consisting of M. C. Burleigh, John H. Burleigh and Oliver H. Lord, who laid the foundation for a business which is to-day large and prosperous. The present officers of the company are: President, O. S. Brown of Salmon Falls; treasurer and manager, Edward H. Gilman of Exeter. The directors include ex Congressman Joshua G. Hall of Dover, ex-Governor Charles H. Sawyer of Dover, John A. White of Concord, Edmund S. Boyer of Great Falls and William D. Sawyer of Dover. The stove works are at Salmon Falls, where there are 19 buildings, all conveniently arranged and equipped for the production, among other things, of more than 50 styles and sizes of stoves. These are turned out under the supervision of Superintendent E. A. Stevens, who, we understand, is an expert in this special line. It is stated that in connection with stoves the company make at these shops furnishings of every description constructed of copper or tin that are used in the manufacture of stoves and ranges.

Sam S. Utter, of 113 Beekman street, New York, returned to the metropolis the past week, after an absence of ten days. During that time he visited the trade in the State of Pennsylvania and spent two days in Pittsburgh, where he was the guest of the president of the First National Bank.

Henry A. Kelley, well known to the trade in New England, has connected himself with Richardson & Boynton Company, and will represent them in the Eastern States. A showroom has been opened at 94 Union street, Boston, where a full line will be carried, and dealers made welcome.

The Art Stove Company of Detroit, Mich., held their annual meeting on Monday, February 6, at which the following directors were elected: Theodore Miller, Neil McMillan, H Leonard Wilton, William H. Fernwood and R. Krakow. The directors then elected Theodore Miller, president; Neil McMillan, vice-president; H. Leonard Wilton, secretary, and William H. Fernwood, treasurer. The secretary reported 1892 as a prosperous year, and that the sale of Laurel stoves and ranges far exceeded those of any other year since the company were organized. They had increased their plant during the past twelve months by the addition of a new warehouse and of ice building and had enlarged their assortment of specialties by a new six hole range and three oil heaters.

A report was recently submitted by the Gas Committee of Manchester, England, to the City Council, with regard to the hire and sale of gas cook stoves. It stated that in November last the chairman and deputy chairman were authorized to secure a plot of ground for the purpose of opening a showroom and workshop. The committee made a careful inquiry as to the stove business, and state that at the end of 1892 there were 2568 gas cookers and fires rented, while 2274 were owned by private persons. The number of stoves sold from 1885 to 1892, inclusive, was 2528, valued at about $15,000. The number rented was 2,568, valued at something over $36,000. On this showing the committee strongly urged the securing of a site for the purpose named. It is not the intention to enter upon any new business in the premises, but to conduct more conveniently and economically that already in existence.

The Ransom Combination Duplex Grate is the subject of a four-page circular which reaches us from the Ransom Grate Company of Albany, N. Y. The device is illustrated, and is claimed to have been adopted by most of the leading stove manufacturers in this country. The list of licensees is said to be rapidly increasing, and in the circular is given a list of stove makers who are now using the grate in connection with their leading goods. They are also presenting a number of testimonials from some of those who have used the Ransom grate.

R. Robinson & Sons, Chicago, have issued an illustrated circular of their superior line of vapor stoves for the season of 1893. This line comprises the Superior process stove, which is made with double tubes, auxiliary generator, glass drip tubes showing the flow of gasoline, plated needle points, nickeled tank rests, burner drums with cast-iron tops and nickel and tile decorations; the Superior single generator, with two top burners and double burner on shelf; the Superior single generator, with three top burners and double burner on shelf; the Superior high junior in two sizes; the Superior low juniors in three sizes. A complete price-list is given as one of the features of the circular.

We have received, with the compliments of Frederick S. Bolte & Co. of St. Louis, Mo, a very pretty folder, the front page of which is embellished with landscape in colors. The folder calls attention to the fact that the firm have opened a new store at 915–917 North Broadway, four doors north of Franklin avenue, where they carry a full line of gas stoves, steel ranges, heaters, gas and gasoline stoves, refrigerators, together with a complete assortment of kitchen utensils.

Fletcher, Russell & Co., Limited, of Warrington, England, have brought out a new gas stove known as the Bengal. It is made in two sizes, the smaller being 24 inches high and 18 inches wide, with the front opening measuring 9½ inches in width. The larger size is 28 inches high and 21 inches wide and is adapted for use in rooms up to 16 feet square.

The Bussey & McLeod Stove Company of Troy, N. Y., will erect a three-story brick building, 40 x 75 feet, on Oakwood avenue, which, when completed, will be leased to the Troy Valve Company. Architect H. P. Fielding prepared the plans and specifications, and awarded the contract for the mason work to John Magill. The building is to cost $15,000, and is to be completed and ready for occupancy by May 1. The first floor will be used as a brass foundry. Work will be begun as soon as possible. The new building is for the purpose of manufacturing the Ross patent mobile wedge valve and hydrants, and it is expected a large number of men will be given employment. The directors of the Troy Valve Company, who were recently incorporated, have elected these officers: President, Enck Bussey; vice-president, William Ross; secretary, Robert Ross; treasurer, Charles A. McLeod.

James Boyle & Co of Salem, Ohio, have gotten out a calendar for the month of February, at the bottom of which is the statement that they "will call again next month." The card measures 6 x 9 inches and is embellished with a picture of the Prize Keystone four-hole cook stove. Above this is the name and address of the company, while below it is the calendar for the present month.

At the annual meeting of the stockholders of the Detroit Stove Works, held at their office, 1320–1360 Jefferson avenue, Detroit, Mich., on Wednesday, February 8, E. S. Barbour was elected president; F. H. Barbour, first vice-president; B. W. Dodson, second vice-president; W. M. Shaddinger, secretary and treasurer; G. W. Gunderson and L. W. Crowley, superintendents.

The Glazier Stove Company of Chelsea, Mich., send us a neat little catalogue printed in tinted ink on good paper, and relating to the leading specialties which they manufacture. The goods shown include oil heaters of attractive design, lamp stoves, cook stoves, gas heaters, ovens, &c. An index and telegraphic code are features of the pamphlet.

The Aurora Vapor Stove Company, of Cleveland, Ohio, announce the Aurora Evaporating Range No. 60 as possessing all the latest improvements. It has two burners in the top plate, a powerful burner in the step, at the side, and one in the oven. The stove is referred to as being finely finished in every particular and of attractive design.

The Art Stove Company, Detroit, Mich., are distributing a very attractive 4-page circular relating to the Crown Laurel Oil heater which they manufacture. The seven points of superiority claimed for this stove are set forth, together with a comprehensive description of its leading features.

J. B. Jones, secretary of the Carton Furnace Company, Utica, N. Y., while on a trip West stopped at Rochester, Buffalo, Cleveland, Dayton, Cincinnati, Columbus and Detroit. A call was also made at the Chicago branch of the company, 83-85 Wabash avenue. The amount of business done by the company in Carton heaters the past season is stated to be very satisfactory.

The Chicago branch of Orr, Painter & Co., Reading Stove Works, has been removed from Kinzie street to 15, 17 and 19 West Lake street. This branch will hereafter be conducted on an independent footing and not in connection with agencies of other stove firms. Two floors of the building have been secured, one of which is used as a sample room and for offices, while the other is intended for storage purposes. A full line of Sunshine stoves and Torrid furnaces is carried by this branch, which is under the management of Chas. A. Rusco, formerly city salesman for Chicago.

The Abram Cox Stove Company have placed on the floor of the sample room of their Chicago branch, 41 State street, one of their new Novelty hot air furnaces, which has a number of interesting points. The ash-pit door is unusually large, extending the full width of the grate section and above the grate. As the grate rests on slides, it can be pulled out with ease to make repairs, which will be appreciated by furnacemen. The cast front of this furnace extends almost its full hight, which enables the galvanized iron for casing to be cut in uniform lengths for every ring. The design of the front is highly ornamental, being elaborated to a much greater extent than is usual in furnace castings, resembling high class stove work in this respect.

PRIZE COMPETITIONS.

WE HEREBY ANNOUNCE a series of six prize competitions relating to trade matters in which our readers are interested. Four prizes of $50, $25, $15 and $10 will be awarded in each competition.

The competitions are open to all and a general participation on the part of the trade is invited.

We shall have the privilege of publishing any or all of the contributions received.

The committee of award in assigning prizes will take into account the merit of the different contributions and their suitability for publication.

PRIZE COMPETITION No. 6.

How Retailers Can Best Advertise and Extend Their Business.

The object of this competition is to obtain practical suggestions as to the methods which the retail dealer in Hardware, Stoves, Tinware, &c., can advantageously adopt in building up his business, and is intended to cover such points as the following:

Advertising in the local papers, with suggestions as to how such advertising should be done and to what extent;
The manner in which circulars and other printed matter may be used;
A description of any special or unusual methods of attracting and holding trade; and
General suggestions in regard to ways in which the business can be extended.

An account of any methods which have been found useful in building up trade will be suitable under this competition.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business February 18, 1893.

Contributions should be addressed to David Williams, 96–102 Reade street, New York, and marked Prize Competition No. 6.

PRIZE COMPETITION No. 7.

Travelers' Yarns.

The traveling salesman is proverbially happy in the stories which he narrates, and this competition is for the purpose of calling out a collection of good yarns for publication. While the attention of travelers is specially invited to this competition, it is open to all. Stories relating more or less closely to trade or business matters will be preferred.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business February 18, 1893.

Contributions should be addressed to David Williams 96–102 Reade street, New York, and marked Prize Competition No. 7.

PRIZE COMPETITION No. 8.

How to Treat Clerks.

Under this competition, beside a general discussion of the subject, such questions as the following may be considered:

The extent to which clerks should be given an opportunity of obtaining a knowledge of the business, and of price-lists, prices, &c.;
Whether it is desirable to have formal rules for the regulation of employees and for the management of the store. If so, a set of rules should be submitted;
To what extent clerks should be held responsible for their mistakes;
Suggestions as to how clerks should be treated in order to secure their most intelligent and efficient work;
Mistakes made in the treatment of clerks.

This competition opens an important subject and it is hoped that it will be discussed fully by merchants and by their clerks from their different points of view.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business February 18, 1893.

Contributions should be addressed to David Williams, 96–102 Reade street, New York, and marked Prize Competition No. 8.

PRIZE COMPETITION No. 9.

Shop System of Keeping Track of Jobs.

This competition is intended to call out information in regard to methods of keeping account of the cost of labor and material on tin-shop work, repairing and new work, inside and outside. In connection with the general subject such points as the following may be touched upon:

Whether blanks or forms are used in connection with such work. (If so, samples should be submitted);
What record is kept of orders, costs of jobs, charges, &c.;
How time occupied in going to and from the job is covered;
Suggestions in regard to the profitable conduct of the shop.

To illustrate the system it is desirable that a specific job (as for example, repairing down spouting and eave trough, or other job of repairing in which new material is used) be referred to and the method of keeping track of the costs in such job fully explained.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business February 18, 1893.

Contributions should be addressed to David Williams, 96–102 Reade street, New York, and marked Prize Competition No. 9.

PRIZE COMPETITION No. 10.

Business Maxims—At Least 10.

Those entering this competition will send at least ten maxims relating to the conduct of business, presenting in a brief and pithy manner practical suggestions which may advantageously be followed.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business February 18, 1893.

Contributions should be addressed to David Williams 96–102 Reade street, New York, and marked Prize Competition No. 10.

PRIZE COMPETITION No. 11.

How Small Retailers May Keep a Record of Prices.

The object of this competition is to call out information or suggestions in regard to the best methods to be adopted in keeping a record of prices, showing cost or selling prices, or both cost and selling prices, of Hardware, Stoves, Tinware, &c., in a small retail store employing not more than four persons in the selling and bookkeeping departments, including the proprietors. Those entering the competition are expected to give a concise and clear explanation of their system, and if a price book is used, to submit as illustrating the system at least three specimen pages. If a price book is referred to it may be of any design or arrangement best adapted to the purpose, and may be original with the contributor or may be one of the different price books on the market. Fictitious names should be used instead of the real names of jobbers and manufacturers.

The committee in awarding prizes will take into account the merit of the different systems described, the character of the descriptions given, and the general utility and interest of the contribution.

First Prize	$50.00
Second Prize	25.00
Third Prize	15.00
Fourth Prize	10.00

This competition will be open until the close of business, February 18, 1893.

Contributions should be addressed to David Williams, 96–102 Reade street, New York, and marked Prize Competition No. 11.

TRADE REPORT.

The Iron Market.

Although there has been little change in the Iron market during the past week, the situation shows some evidence of improvement. The encouraging feature is an increased demand for some lines rather than stiffening in prices. The demand is doubtless large, but apparently not large enough to advance prices to any extent. Any improvement which may have taken place has not extended to this market, and no increase in sales is noticed. In certain sections where the market is active and no complaint of the amount of business offered, prices are not satisfactory, and other than regular brands of Pig Iron are irregular in price. The cause of the advance in Bessemer Pig Iron over prices which had been ruling is found in the fact that the output of the largest producers in the region of Pittsburgh was considerably curtailed by the idleness of some of their stacks. Two other large Steel making concerns were using more metal than they were producing, which made it necessary for them to go in and buy, and the same is true of one or two of the Wheeling concerns. The withdrawal of these three or four concerns from the market as sellers and their appearance as buyers naturally caused a drain on the supply, and for a time Bessemer Pig for early shipment was hard to obtain and commanded good prices. It is probable, however, that the supply will be considerably increased very soon, as two idle stacks in the Pittsburgh district and several in the Wheeling district will be making Iron before this month is out. A good many contracts have recently been placed for Wire Nails and the indications are that there will be a very heavy demand for Wire this year. On account of the low prices ruling for Structural Material, it is expected that the consumption will very materially increase and be much heavier this year than in any previous year. All in all, the outlook for a satisfactory volume of business in the principal articles of Iron and Steel manufacture is very encouraging. It is the general impression, however, that prices will continue to rule largely in buyers' favor, although on some lines, on which prices are very close to cost of production, it is not improbable that an improvement will take place.

In the West the improved condition of the weather is now a little more favorable to business. The railroads are moving freight more promptly, owing to the gradual disappearance of snow and ice. It will take two or three weeks, however, to enable them to catch up with accumulated traffic and to keep matters in the usual satisfactory shape. Everything is looking better in both raw material and finished products, with the single exception of Plates. The volume of trade, taking the whole line of Iron and Steel products, was larger last week than any other week thus far this year, with a distinct tendency to firmness in prices. For the two weeks past business in Pig Iron has been satisfactory. More orders are in sight, however, some of which will undoubtedly be closed soon. The activity is ascribed to the increased belief among consumers that prices are as low now as they are likely to be during, at least, the first half of the year. Quite a number of the largest buyers had been figuring on their contracts since about the first of the year and endeavored to push prices down lower, but find that bottom has evidently been reached. An encouraging feature of the situation is that considerable tonnage was entered at prices above the minimum recently current. Plenty of inquiries are reported for Southern Coke, but prices are too high as yet for much business in that line. The disparity between the selling price of Northern and Southern Iron is too great to enable much of the latter to be sold. The leading companies are still holding prices firmly, but smaller concerns are taking about all the business now doing in Southern Coke. Lake Superior Charcoal has not been in much demand, but one transaction is noted of a round lot at a good price. While new orders are not numerous, yet consumers are taking more Charcoal Iron than they had anticipated, and many of them are increasing their old contracts from 25 to 30 per cent.

In Southern markets there continues to be an easy feeling in the market for Pig Iron, and while there is a fair demand for current or short forward consumption, there is no disposition shown to buy large blocks of Iron for long time delivery, nor would the furnaces entertain them at present prices. The purchases have been mainly 500 to 1000 tons, and for this month's and March and April delivery, with smaller lots running down to one carload, but in the aggregate they make a fair volume of business. There is some inquiry for Lake Superior Charcoal Iron, but Southern Charcoal Irons are quiet.

There is no improvement reported in the demand for Pig Iron in the New York market, and quotations remain unchanged as follows: Northern brands at $14.75 @ $15.25 for No. 1; $14 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14 75 @ $15 for No. 1; $13 75 @ $14 for No. 2 and No. 1 Soft; $13.25 @ $13.50 for No. 2 Soft.

In Philadelphia there has been a good deal of business done in Pig Iron, but without improvement in prices. Indeed, the trade have settled down to the conviction that there is not likely to be any improvement until some decided increase in demand is met with, and as most people are already working on a larger scale than usual it is hard to see at which point to look for improvement. Sales have been at all sorts of prices within the limits of quoted prices, varying according to quantity, brand, delivery, &c. The prices for Philadelphia (or equivalent) are as follows:

American Scotch, No. 1X	$17.00	@	$17 25
American Scotch, No. 2X	16.00	@	16 25

A remarkable feature of the Pittsburgh market during the past week was that there were more buyers of Pig Iron than sellers. This is a remarkable statement to make, but it is true. Bessemer Iron for prompt shipment was urgently sought for by buyers, and in some cases without success, even when offers of $13.50, Pittsburgh, were made to secure the Iron. Prices for Foundry Irons are quoted as follows:

No. 1 Foundry	$13.75	@	$14.00, cash
No. 2 Foundry	12.75	@	13.00, "
Charcoal Foundry No. 1	17.00	@	18.00, "
Charcoal Foundry No. 2	16.50	@	17.00, "

In Chicago Local Coke continues very active, and numerous sales are reported of good-sized lots ranging from 500 to 1500 tons for scattered deliveries. Improved conditions in the movement of freight are having their effect in stimulating business, and inquiries are more numerous. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50	@	$17.00
Local Coke Foundry, No. 1	13.25	@	13.75
Local Coke Foundry, No. 2	12.75	@	13.25
Local Coke Foundry, No. 3	12.50	@	12.75

Southern markets have been little effected by the advance of Bessemer Iron in Pittsburgh, Preliminary reports of stocks in the South indicate a small reduction, but there are well authenticated reports that some furnaces have quite an accumulation of Iron which they are anxious to sell. There are applications to have deliveries hastened on existing contracts and other indications that consumption is active and of large volume. Cincinnati quotations are as follows:

Foundry.

Southern Coke, No. 1	$13.25	@	$13.50
Southern Coke, No. 2	12.00	@	12.25
Southern Coke, No. 3	11.50	@	11.75
Ohio Soft Stone Coal, No. 1	16.00	@	16 25
Ohio Soft Stone Coal, No. 2	15.00	@	15.25
Mahoning and Shenango Valley	15.25	@	16.25
Hanging Rock Charcoal, No. 1	19.00	@	19.25
Hanging Rock Charcoal, No. 2	18.00	@	18.50
Tennessee and Alabama Charcoal, No. 1	15.50	@	15.75
Tennessee and Alabama Charcoal, No. 2	14.50	@	4.75

Billets and Rods.—There has been no business of consequence in this market in foreign or domestic material.

Steel Rails.—Some large contracts have been closed by Eastern mills, the week's aggregate of sales, in which all the works participated to a greater or lesser degree, figuring up to the best record thus far made this year in a similar space of time. The aggregate is 75,000 tons.

Metal Market.

Copper.—The situation remains practically the same as outlined last week. Although business in some lines of Copper and Brass goods has been checked to a certain degree of late by unfavorable weather, work in the various branches has continued active. The prospects for the manufacturing industries are referred to as being very encouraging, with particularly bright indications for an unprecedented consumption of Wire for electrical purposes. Despite these conditions and the fact that production of the metal is restricted to fairly well determined wants, the buying of Ingot continues slow in this market, and nothing in the nature of active speculative interest develops.

Pig Tin.—Speculative dealings have been on a more restricted scale, and in other directions the business, to all accounts, loses somewhat by comparison with that of the preceding week. The falling off in jobbing and consumptive trade buying is attributed in a good measure to liberal deliveries latterly on old purchases of "futures" and considerable quantics of Tin afloat available for delivery on contracts still outstanding. The speculative branch of the trade is indirectly affected, but surface indications are that excess of "long" over "short" interest in nearby futures cuts a more conspicuous figure there, leaving it uphill work for the "bulls" to make headway.

Pig Lead.—The sales reported for the past week involve about 500 tons, the greater portion of which were for near future delivery. Consumers have manifested no particularly lively interest and speculative spirit continues exceedingly tame. The alleged curtailment of production during the past six weeks has, in fact, been the chief, if not the only, support to values.

Spelter.—Offerings by some Western smelters have been a little urgent and of a nature reflecting pressure to sell for shipment during the three months ending with June. Along with data of output here and advices of poor chances for selling in Europe at any profit, this offering is suggestive, indicating that heavy stocks in smelters' hands are becoming tiresome, and that the home market is preferred to the European outlet at present.

Antimony.—The demand has been moderate and chiefly of a jobbing nature. Prices rather easy, but showing no radical change.

Tin Plate.—Orders for Cokes for spring delivery have fallen off, and outside of what may have been done direct in Oil and other special sizes, the business of the week makes an indifferent showing. Spot sales have been of strictly routine character, and rather small in the aggregate amount. Assortments here are somewhat broken, but the general supply appears adequate for present needs, and purchases are made without a great deal of difficulty at prices that ruled last week. Cable report notes that the stock at Swansea is now about 214,000 boxes, against 170,000 boxes a year ago. Uncertainty in future legislation deters buyers from purchasing in quantities larger than for immediate requirements. With this exception the trade throughout the country is in a healthy condition, and a good year's business is anticipated.

Coal Market.

With milder weather and plenty of Coal, the Anthracite market is "sloppy." That is to say, while the combine hold to the regular schedule, there is a plenty of Coal around at lower prices. Shippers speak of considerable shading, Stove Coal having been sold in New York as low as $4.50, f.o.b., per ton, which is 25¢ under the gross circular. All domestic sizes are in excess of the demand. Steam sizes are easier and better in supply, but Pea Coal is slow in delivery, so that new purchasers take their turn. Pea is $2.25, alongside. Buckwheat $2 @ $2.10, alongside, and not as easy as Pea. Collieries in Schuylkill County are starting up again, now that cars can be had to carry off the product.

Bituminous Coal is $3.50, alongside, and in some cases $3.75 is paid, but the market is the same as a week ago. Shippers are behind on contract orders, and on others there is some delay, chiefly by reason of lack of cars. In this respect the situation is improving. Tidewater shipments have been resumed from New York harbor, but the greater part of the Coal going eastward is being shipped via all rail routes.

Week's production, 829,831 tons; for the year, 3,581,604 tons; Reading tonnage, 450,000 tons. The Pennsylvania Railroad tonnage for the week was 311,648 tons Coal and 112,253 tons Coke.

A Columbus, Ohio, special says that operators representing 95 per cent. of the soft Coal output of Hocking Valley have agreed to form a selling corporation, and are taking steps to carry out the idea, but have abandoned the plan for a trust.

The Glendon Colliery at Mahanoy City, Penn., formerly owned and operated by J. C. Hayden & Co., has been leased by the Lehigh division of the Reading Coal & Iron Company. This colliery has an annual production of 100,000 tons. To increase the output great improvements are in contemplation.

A new use has been found for Culm. The Lehigh & Wilkesbarre Coal Company have just contracted for having an 8-inch bore hole sunk over the abandoned workings of their great colliery—the Nottingham—at Plymouth. It will penetrate to a depth of nearly 700 feet, and will then be used to flush the worked-out portions of the mine with Culm.

Under this flushing process a new support is furnished, and new chambers and breasts can be driven around the solidified Culm, thus making it possible to take out all but 5 per cent. of the entire deposit of Coal as it originally existed.

Financial.

The so-called "gold scare" is the feature of the week in financial circles, occasioned by the low state of the Treasury and the continued large exports, which exceeded $4,000,000 for the week ending 11th inst., and more orders for shipment remain to be executed. Exports of specie and bullion from New York in January were nearly $15,000,000, against only $2,000,000 for January, 1892. For the same month imports amounted to $59,540,000, of which more than half were free goods, the largest item being about $14,000,000 in coffee. At the same time exports dropped to $24,801,000, exclusive of specie, facts that are calculated to attract attention in their relation to the future balance of trade. For seven months exports from New York, exclusive of specie, amount to $208,506,000, against $254,341,000 for the seven months ending January 31, 1892. Secretary Foster, in a conference with local bankers, received assurances that sufficient amounts of gold would be transferred to the Treasury to tide over the present emergency, but this arrangement was looked upon only as a makeshift, until Congress can act. The proposed issue of bonds was generally regarded as only an additional issue of paper that would not avail as a remedy so long as silver purchases continue. The subject of "special deposits" of gold was discussed by the associated banks, with the conclusion that they could only be received as "lawful money." Bank deposits amounting to about $500,000,000 weekly could not be returned in gold, which, however, few customers could desire.

The Stock Exchange markets have been less active, the speculation in industrials having subsided.

A decision has been rendered by the United States Circuit Court of Appeals for the third circuit, in the case of John Wanamaker, appellant, vs. the Enterprise Mfg. Company of Pennsylvania, appellee. This was an appeal by John Wanamaker from the decision in the suit in which the court rendered a decree sustaining the patent (No. 271,398, January 3, 1883) relating to the Meat Chopper of the Enterprise Mfg. Company, and awarding injunction and damages against him. This decision, on appeal, was affirmed with costs. The Enterprise Company have thus again maintained their Meat Chopper patents against infringement.

An Egyptian scythe, dug up on the banks of the Nile in 1890, and said to be as old as Moses, is exhibited in a London museum. The shaft of the instrument is of wood, set with a row of fine flint saws, which are securely cemented in a groove.

Chicago Report.

Scrap.—Business is again resuming its old-time volume, but the demand is heaviest for cheap stock. Dealers quote the following buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.50	....
Machinery Cast	10.00	....
Malleable Cast	8.00	....
Stove Plate (free of burnt)	7.50	....
Burnt Iron and Grate Bars	5.50	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single sheets and Rings	12 00	....
Old Gas-Pipe and Boiler Tubes	9.00	..
Cast Borings	5.00	....
Turnings	7.00	....
Horseshoes	13.00	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	¾¢

Anthracite.—The demand continues very active and stock piles in the local yards are rapidly diminishing, but prices are still unchanged.

	Egg, Grate.	Sto. and Ch.
Chicago, Ill	$5.85	$6.10

Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

Tin-Plate Production.

The Secretary of the Treasury, says our Washington correspondent, is very much gratified at the continued favorable output of tin and terne plate under the impetus given to that branch of industry through the stimulating effects of the protective provisions in the Tariff act of 1890. As those provisions are binding for the term specified, any change would be a breach of faith on the part of Congress and the Executive.

The report of Special Agent Ira Ayer on tin and terne plate production in the United States will not be completed for some days. The following is an extract from a letter to the Chief of the Customs Division, United States Treasury, on the subject:

"You will be glad to know that the production for the last quarter (December 31, 1892) is very nearly 20,000,000 pounds of tin and terne plates proper, besides the manufactures of American sheet steel tinned. This is nearly double the production for the previous quarter. The number of producers is the same as the previous quarter, viz., 32."

Some of the Panama Canal officials must go to prison for five years, including the veteran president, Ferdinand De Lesseps, and his son Charles. Eiffel, who received a lighter sentence, will appeal.

CONDITION OF THE

Hardware Trade.

CORRESPONDENTS from all over the country refer to the large volume of business, the demand apparently setting in very satisfactorily. The severe weather which has prevailed has interfered seriously with business in many parts of the country and especially with the delivery of goods on account of the congested condition of the railroads. Retailers are beginning to place their orders quite freely and the jobbing houses are thus well occupied. Larger buyers are purchasing freely of staple goods and of miscellaneous Hardware needed to complete or replenish their assortments. The impression prevails that in many lines, heavy goods especially, prices are low enough to justify liberal purchases, but notwithstanding the amount of business done there is but little improvement in the tone of the market. There is somewhat more complaint in regard to collections than there has been.

Notes on Prices.

Cut Nails.—Owing to only partial adoption of the price-list on Cut Nails, there is considerable confusion in the market in regard to quotations, but as a rule prices are named by the mills on the basis of the old card. Local dealers are endeavoring to adhere to the new list, but until it is generally adopted by the mills it is not easy to do this satisfactorily. The Western mills adopted the Wire Nail card at the meeting held in Pittsburgh, on the 15th inst. Small lots from store in New York are quoted regularly at $1 off the new list. There has been considerable activity, and the prospect is regarded as very promising for a large demand during the season.

Advices from Chicago.—Manufacturers' agents report a much better business in Cut Steel Nails, with occasional orders running into very respectable quantities, The discussion of the new Eastern card has not terminated in an overwhelming sentiment in its favor. Small lots from stock sell at $1.65.

Wire Nails.—The Wire Nail market is certainly in better condition than for some time. Prices are somewhat higher and well maintained on the basis established by the manufacturers at their meeting in Chicago, to which reference was made in our last issue. The market is represented by the quotation of $1.40 to $1.45, the former being the lowest manufacturers are willing to name. There is a large movement in this line and manufacturers are busy.

Advices from Chicago.—A much stronger feeling prevails in Wire Nail circles. The trade are waiting to see if present prices will be maintained. This is the natural result of failure to keep agreements in the past. Manufacturers, however, appear to be undisturbed, asserting that no signs of weakening are apparent, and that buyers cannot hold out much longer with spring so near at hand. They also claim that indications now favor closer relations than ever among the leading makers. The mills in Northern Ohio are reported to be arranging for a consolidation of the interests. If they unite and a single selling agency controls their vast output the situation will be greatly simplified and reckless competition will be nearing its end. Small lots from stock are unchanged at $1.60 to $1.65.

Barb Wire.—The market in Barb Wire is characterized by a somewhat better tone, and some of the extreme prices named by manufacturers have been withdrawn. The quotation of $2.40 to $2.45 for Galvanized Four Point at mill, carload lots, represents the market, though some manufacturers refuse to meet these figures. The demand for Barb Wire is setting in more actively and the prospect for a heavy trade is excellent.

Advices from Chicago. — Barb Wire manufacturers are in receipt of an increased number of orders, and the outlook steadily improves. The weather has not been favorable for the Barb Wire trade, but the severity of the winter is now broken and from this time forward orders are expected to flow in with an increasing current until the hight of the spring season is reached. Manufacturers report their agreed price of $2.20 for carload lots of Painted well sustained. Jobbers, however, continue to quote from stock at $2.60 to $2.65 for Galvanized, with 40¢ off for Painted.

Bright Wire Goods.—At the present time the market in Bright Wire Goods is not characterized by its usual evenness, and there has been something of a break in prices, resulting in considerably lower quotations in some cases.

Tinware.—The market for Tinware is somewhat irregular and the competition between the different manufacturers is animated. The tendency which has existed for some time of quoting net prices instead of per list and discount has developed so far that to all close buyers quotations are made in net figures. The manufacturers refer to the inconvenience of this method and buyers to the care which is necessary in ordering goods if there is a careful comparison of prices made by competing houses.

Iron Rivets.—The Rivet market is characterized by a good deal of demoralization. Competition between the manufacturers is active and lower prices have been developed during the past week or two.

Tackle Blocks.—The condition of the Tackle Block market is far from satisfactory and the competition has developed exceedingly low prices, and even the small trade are able to purchase at figures which some time ago would not be considered.

Lawn Mowers.—Graham, Passmore & Co., Philadelphia, issue the following discount sheet relating to their line of Mowers:

	Per cent.
All Hand Lawn Mowers, except Style A	70
Style A, malleable steel Mower	60
30 inch Pony Lawn Mowers	40
36-inch large Horse Mowers	30
Collectors	20
Lawn Sweepers, hand or horse sizes	30
Extra parts or repairs	40

The discount sheet also illustrates their Style A malleable steel Mower, which is listed at $28 and $31 for the 17-inch and 19-inch respectively. Their Grass Collector is also shown and the following list prices given:

	Each.
14 and 16 inch	$2.50
17, 18 and 19 inch	2.75

Soldering Fluids.—J. F. Farrington, 188 Grand street, New York, is sole agent for Gedney's Soldering Fluid. The manufacturers state that in using it there is no liability to rust or corrode the surface of the metal, but that it is left bright and clean; that it results in a saving of solder and causes it to flow freely; that its use is accompanied by only a small percentage of leakages; that there is a freedom from unhealthy and upleasant smells, and that it reduces labor and the cost of material. It is sold in carboys and barrels at 2 cents a pound, and $1.50 charged for the package, which amount will be refunded when the empty package is returned. Samples of the Fluid are furnished free upon application.

Baltimore Chemical Company, Seventh and Gough streets, Baltimore, Md., manufacture the Perfection Soldering Flux, which is put up in concentrated liquid form, and require about two parts of water to one of Flux, for general use. The point is made that the Flux ready for use costs less than 12¢ ℔ gallon. It is remarked that there is no risk of the extra strength being wasted, as the workman must dilute it, as it will not work otherwise. Samples are put up in 2 and 3 gallon kegs at 75¢, $1.30 and $1.85, including the kegs. Prices for regular packages are as follows, subject to a discount of 5 %:

Barrels, about 500 lb, ℔ lb	3½¢
Half barrels, about 300 lb, ℔ lb	4¢
Kegs, about 110 lb, ℔ lb	4¢
Kegs, about 55 lb, ℔ lb	4¢

A charge of 75¢ is made in 55 lb kegs, other packages being furnished without charge.

Rosin.—No very important change has recently taken place in the Rosin market, but prices are considerably higher than they were some time ago. The condition of the market is reflected in the following quotations (per 280 lb), which are made by F. W. Blossom, 124 Water street, New York:

A, black	$1.45
B, common	1.46
C, strained	1.47
D, good grained	1.48
E, No. 2	1.52
F, good No. 2	1.60
G, low No. 1	1.70
H, No. 1	2.05
I, good No. 1	2.30
K, low pale	2.85
M, pale	3.75
N, extra pale	3.95
WG, window glass	4.15
WW, water white	4.30

Oil Well Cordage.—The dealers in Oil Well Cordage held a meeting in Pittsburgh last week, at which a slight advance in prices was made, and it was mutually agreed that the established price be closely adhered to, which has not been done for some time past. Represented at the meeting were the Oil Well Supply Company, National Cordage Company, Jarecki Mfg. Company, Frick, Lindsay & Co., and Bovard & Seyfarg Mfg. Company. The price of Oil Well Cordage heretofore has been 12 cents per pound, but it was decided at the above meeting to advance the price to 12½ cents per pound, and it is claimed this price will be strictly maintained.

Glass.—There have been few developments of interest in the American Glass market during the past week, the attention of the trade having been directed to the new discounts made by the National Window Glass Company, as given in our last issue. Reports from factories indicate that the demand for Glass remains steady, while production is falling off and will continue to be lighter during the next few weeks than it has been. Some factories in the natural gas belt have suffered considerably from shortage of gas, causing pots to go out of operation in some cases. Local trade is fair, and out-of-town business is reported as satisfactory. It is understood that a movement is on foot among New York importers of Window Glass, having in view some definite arrangement to insure the stability of prices. At present the market is in a demoralized condition, and Glass is sold at from 80 and 5 per cent. discount to 80 and 10 per cent. discount. The Plate Glass market is quiet, with limited demand, and no change in quotations. Quotations on Glass are as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; 100 boxes or over, 80 and 10 per cent. discount; less than 100 boxes, 80 and 5 per cent. discount. French Window Glass, 80 per cent. discount to 80 and 10 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔ lb.		@	$0.03½

Mixed Rope	℔ lb	¾ @	⅞¢

Trade Notes.

The Backus Mfg. Company, with factory at Williamsport, Pa., have issued a catalogue of Backus Patent Portable Steam Radiators for gaseous fuel, radiating mantels, open fire-place gas logs, &c. The goods are tastefully illustrated by means of engravings printed in colored ink, while full descriptive particulars tell how the goods are made and how they are operated. A long list of testimonials show the estimation in which the Backus Portable Steam Heater is held by those who have used it. A feature of the little pamphlet is a descriptive price list.

Edward A. Brigham, 40 Oliver street, Boston, Mass., issues a little circular telling about Parson's Manganese Bronze. This metal, which is manufactured in England, is described as the steel of the bronze alloys and is adapted to propeller blades and many other purposes. It is made in five qualities, the first three for use where strength is wanted and the fourth and fifth for anti friction purposes. It is said to be especially suitable for drop forgings and is used for stampings of all descriptions. Edward A. Brigham is United States agent, while the agent in New York is G. Douglas Petrie, 37 Broad street.

Chas. A. Conklin Mfg. Company, Atlanta, Ga., advise us that they are this month opening a branch of their Tin-Plate business at Savannah, Ga. They will in future carry most of their stock at that point, importing direct from England to Savannah and using that port as a distributing depot. Messrs. Conklin & Co. consider the facilities afforded at Savannah to be so favorable to this business that they anticipate great advantage both to themselves and their customers in the tinning and sheet-metal lines will accrue from the new arrangement.

James A. Coe & Co., 106 and 108 Mulberry street, Newark, N. J., inform us that they have secured the sale of a thoroughly reliable American Roofing Plate—the Staple Terne—which they are now offering to the trade, made IC, 14 x 20 and 20 x 28.

N. & G. Taylor Company, Philadelphia, make special mention elsewhere of Heater Pipe Bright Tin, made at their own works, which they are prepared to offer to the trade in IC and IX thickness, and of various sizes, as detailed.

Kankakee Mfg. Company, Kankakee, Ill., call attention in another column to their Kankakee Refrigerators, of which they have a number of new designs with improved fittings.

Thomas Sands, Nashua, N. H., announces in another column that he is prepared to enter into correspondence with parties desirous of using the Flandera process for tinning cast iron, which is stated to have been adopted by several large firms in this country. W. T. Flanders will superintend the building and starting of any new plants.

The Riehle Bros. Testing Machine Company announce that beginning April 1, J. R. Matlack, Jr., will act as their

representative at the World's Columbian Exposition, Chicago, and can be found, previous to the opening of the exposition, at the office of R. W. Hunt & Co., Rookery, Chicago.

Hibberd & Spinner, 9 Cliff street, New York, inform us that, complying with a demand from the trade for additional sizes of the Excelsior Oval Former recently brought out, they are now prepared to supply it in 1½ x 20 inch and 1½ x 31 inch sizes in addition to the 2 x 30 inch originally made.

Hart & Crouse, Utica, N. Y., in a prominent announcement elsewhere, show cuts of their Royal Hot-Water and Steam Boilers. They also show a Combination Heater, as well as Hot-Air Furnace.

The Pittsburgh Reduction Company of Pittsburgh, manufacturers of Aluminum, whose works are located at Kensington, Pa., will shortly commence to make extensive improvements and additions to their plant, which will very largely increase their capacity for the manufacture of Aluminum. It is said that upward of $150,00 will be expended for this purpose.

At a meeting of the stockholders of the Bostwick Fire Proof Steel Lathing Company, held at Wheeling, W. Va., last week, the following Board of Directors was elected: J. A. Miller, E. C. Myers, H. B. Baguely, W. D. Johnson and William Ellingham. A partial organization was effected by the selection of J. A. Miller for president. A meeting will be held some time in the latter part of this week for the purpose of finishing the selection of officers and taking steps to push the business more actively than ever before.

The Eustis Mfg. Company, Bayonne, N. J., issue a circular announcing that the Bronson Supply Company, Cleveland, Ohio, and 72 Beekman street, New York, have been appointed sole selling agents in the United States and Canada for the Puritan House-furnishing specialties manufactured by them. They suggest that all orders and communications relating to these specialties be sent to the Bronson Supply Company, and hope that this business change will facilitate the execution of orders and be a convenience to their customers.

The Central Expanded Metal Company of 531 Wood street, Pittsburgh, Pa., are meeting with a very gratifying demand for their Expanded Metal, and it is being specified in a number of prominent buildings in this and other cities. It is being largely employed in connection with the company's solid partitions, constructed of studding made of ⅞ x ⅞ inch channel iron or steel placed 16 inches on centers. The metal lathing is attached to the studding and is then covered with mortar or cement in the usual manner. These metal studs, metallic lathed and plastered on both sides, give a partition which is claimed to be not only light and strong, but of an absolutely incombustible nature. These partitions have been used in a large number of prominent buildings in Chicago, and are now specified in that of the New York Biscuit Bakery, which will require 11,000 yards of expanded metal; the De Gerald Apartment Building, requiring 15,000 yards; the Stiles Hotel, requiring 30,000 yards; Leland's "View" Hotel, now in course of erection in Jackson Park, which will require 52,000 yards and the Indiana Hotel, which will take 75,000 yards of Expanded Metal. In the latter case the Expanded Metal is used in connection with wooden studding and joist. The construction employed gives a solid partition, which is claimed to be substantially as strong as a brick wall, while possessing the advantages of saving floor space and economy of cost.

Among recently authorized corporations in Illinois are the following: McAleenan & Co., at Peoria; capital stock, $15,000; for the manufacture of boilers and sheet iron work; incorporators, William J. McAleenan, Eugene McAleenan and Maggie A. McAleenan. The Cushman Telephone Syndicate, at Chicago; capital stock, $1,000,000; for the manufacture of telephones and switchboards and to construct telephone exchanges; incorporators, H. L Hollister, Israel M. Hay, J. S. Given and John D. Cameron. The Havana Metal Wheel Company, Havana; to manuacture metal wheels; capital stock, $25,000; incorporators, Harvey J. Phelps, Lewis E. Waterman and Orlando B. Thoop. The North Side Electric Street Railway Company, at Chicago; capital stock, $500,000; for the construction and maintenance of a system of street railways in Chicago; incorporators, August Rieke, F. W. McNally and William Kilpatrick. The Augusta Electric Light & Mfg. Company, at Augusta, Hancock County; capital stock, $16,000; to furnish light and power for the manufacture of brick, tile and pottery; incorporators, William Gelm, B. C. Crain, D. P. Coffman, R. J. Crigson and O. L. Pitney. The Babcock Fire Extinguisher Company, at Chicago; capital stock, $100,000; for the manufacture of fire-extinguishing apparatus and appliances; incorporators, William C. Stoddard, William Wilkinson and Alfred Holman. The Bennars Hubless Adjustable Self Oiling Carriage Mfg. Company, at Chicago; capital stock, $200,000; for the manufacture of carriages; incorporators, William Bennars, Hector A. Bennars and Albert Jacobs. The Allan Maxwell Mfg. Company, at Chicago; capital stock, $300,000; for the manufacture of chilled gear wheels and electrical supplies; incorporators, J. G. Hambrick, R. R. Kerr and D. G. Laxson. The Henry Knapheide Wagon Company, at Quincy; capital stock, $20,000; for the manufacture of wagons and vehicles; incorporators, H. E. Knapheide, M. C. K. Germann and A. M. Knapheide. Chicago Carpet Sweeper Company, Chicago; capital stock, $50,000; incorporators, James Rosenthal, Herbert Till and Louis Hening. The Kaplar Patent Tinware Mfg. Company, Chicago; capital stock, $20,000; incorporators, Harris Kaplar, Jacob Burkhart and others. The Breitling Metal Ware Mfg. Company, at Chicago; capital stock, $75,000; for the manufacture of metal ware; incorporators, Charles Breitling, Gustav Steiglitz and Adolph Hartman. The Smith-Hill Foundry & Machine Company of Quincy, Ill., have increased their capital stock from $75,000 to $100,000.

J. Geo. Kurtz, Jr, & Bro., Philadelphia, Pa., who are agents for the Ringen Stove Company, St. Louis, Mo., report an excellent outlook for a large spring trade. This house have sold the Quick Meal gasoline and gas stoves for a number of years past, and report a steadily increasing demand for them. They recently placed an order for eight carloads, and this no doubt will be supplemented with additional orders as the season progresses.

The Smith & Anthony Stove Company have had a regular "fall boom" since they commenced advertising their new brick-lined furnace known as the Hub Heater, additional typewriters and other sure signs of a lively business having apsure signs of a lively business having appeared at their Boston office. It is possible our readers may hear further of this heater in the not very distant future.

Ice on the lakes is the heaviest for a century. In one place, eight miles from shore, it is eight feet thick.

Natural Supplies of Fuel.

There has been much said about the ultimate exhaustion of the coal deposits, and the imaginations of some writers have enabled them to depict a woful state of affairs when this comes to pass. People who make such predictions are very much like those teachers of natural philosophy who look forward to a time when not only all available fuel will be exhausted, but when even the sun will have expended all its heat; that is to say, will have cooled down to a common temperature with all other bodies in the universe, so that there will be no longer any one thing hotter than any other, and therefore the motion and activity of the universe will cease. Should such a period ever come, we, the present generation, need not fear to live long enough to be frozen out of existence by the lack of means wherewith to supply warmth to our bodies. Such predictions, however, may be taken into brief consideration. In the first place, they are much like speculations as to what exists at the center of the earth, based upon what knowledge can be gained by scratching its skin. Valuable as are the researches of geologists and mineralogists, they can tell us nothing of the state of things more than thirty miles below the earth's surface. No upheaval of the crust of this planet that has ever been traced has been able to disclose what lies lower down than that. So all that these teachers have been able to see of the grand cycle of natural forces is, comparable to what we know of the earth's interior, a mere nothing in proportion to what might be known were our power to see and understand the hidden mysteries of all created things complete.

What Becomes of Burned Fuel?

Nothing is destroyed in nature or by any of the arts of man. Little as we know, we know this. Things change their form, but the material of which they consisted still remains. When coal, or wood, petroleum, gas—natural or artificial—is consumed in furnaces, stoves or lamps, carbon is combined with the oxygen of the air to form a gas that soon diffuses into and through the atmosphere, and hydrogen also combining with oxygen passes into the air as vapor of water. We therefore have brought about two changes by the process of combustion—a change of form and a change of location. What we dug out of the earth, what was pumped out, what flowed out spontaneously, or what grew by the slow process of vegetation, as the wood we have made use of as fuel, has been changed from a solid to a gaseous condition; or, if gas, changed from one kind of gas to another, and instead of being stored as formerly, in and upon the crust of the earth, has now been stored in the atmosphere. Let us follow it a little further. Presently the water vapor is condensed and falls as rain upon the earth. But plants and trees must feed as well as drink, and the carbonic acid we have sent shooting out of chimneys and smokestacks is absolutely essential to their subsistence. All their woody framework is built up principally of the carbon extracted from the carbonic gas in the air. They take no carbon from the soil. What they get through their roots is something very different from carbon. When wood is burned most of these latter substances remain in the ashes. The carbon from the atmosphere enters growing trees and plants through their leaves, and is again built up into wood. It was through this process that the carbon of the coal measures was originally collected from the atmosphere, and it has been going on since the world began.

Compensations.

We can see, therefore, that there are compensations in nature, and that these, so far, have been equal to all emergencies. The time may come when coal supplies will give out, when oil wells will cease to gush, when natural gas will fail. When this time comes there will be no ground to fear a scarcity of fuel. Nature is ready to manufacture it as needed. It may then become a profitable industry to grow fuel as cotton is now grown for market, and when this has become a necessity, we shall have learned how to make out of it an artificial fuel as dense and serviceable as the coal we now dig out of mines. It is not at all beyond the limits of possibility, or even of probability, that fuel so made will be supplied as cheaply as natural coal is at present put on the market by the "coal combines" that are, just now, the target of so much public censure. Peat is a fuel formed by carbonized vegetation. In this fuel, extensively used in some parts of the world, carbon from carbonic gas of the atmosphere is reduced to a solid form by vegetation, and then by slow processes the vegetation is carbonized again in the formation of peat. As confirmation of the opinion that a good dense and solid artificial fuel will be forthcoming when needed, it may be said that such fuel has already been made from peat by heavy pressure. But in the fuel of the future that will become a substitute for anthracite and bituminous coal when these are exhausted, we shall not wait for the slow natural processes of carbonization. As in charcoal burning, this will probably be done artificially.

Ventilation and Labor.

It is hardly conceivable that the large majority of people in this scientific and enlightened age and country continue to neglect the important and even vital subject of ventilation as they do. Notwithstanding all the agitation on the subject and all that has been written about it; notwithstanding the facilities within reach of all for the ventilation of dwellings and other buildings by means of simple and inexpensive devices; notwithstanding painful personal experiences of the baneful effects of impure and vitiated air, in loss of health and energy—headaches, prostration, irritability and other distressing symptoms directly due to this cause—the generality of people go on their way, for the most part, ignoring one of the most essential elements of comfort and well being. Not a tithe of the attention that is its due is yet paid to the proper ventilating of our houses, offices and other buildings wherein we live or work. Much solicitude is, as a rule, felt in regard to the efficiency of the drainage, while the arrangements for the escape of impure and the admission of fresh air are usually neglected. And yet they are almost of equal importance in the attainment of sanitation and wholesomeness.

Economy of Good Ventilation.

Many employers do not realize that their best interests are involved in securing efficient ventilation of the places where their employees pass their days. A little more attention to the matter would insure better health, and, therefore, better and more energetic brain and hand work, from those who are compelled to labor in confined spaces. The fixture of a little ventilation wheel in the window of an office has been known to effect the complete disappearance of headaches and lassitude which had previously prevailed among the clerks to the detriment of the business of the firm. Physical, and consequent mental, improvement has constantly been noticed among the workers in factories and shops after the introduction of an efficient ventilating system. Every one admits these facts, and then usually does nothing.

Chicago Railroads.

The magnitude of the railroad interests of Chicago is shown by some interesting facts recently compiled by a local paper. There are 28 distinct railroad companies, operating 41 roads, on which 1386 trains of all classes arrrive and depart daily. Freight trains constitute the smaller part of these arrivals and departures, comprising 274 merchandise trains and 164 grain,

stock and lumber trains. The passenger service is divided between 670 suburban and accommodation and 278 through express and mail trains. These 28 railroad companies own or control no less than 40,000 miles of road. Their direct connections, of course, would swell the mileage much higher, as solid trains run east from Chicago to the Atlantic, west to the Pacific, south to the Gulf, &c. It is believed that no other city in the world can make a showing in any way comparable with this.

Manufacturing Specialties.

A manufacturer of a line of standard goods had been complaining of the total lack of profits in his business to a sympathizing friend, when the latter was struck by a brilliant thought and asked, "Why don't you take up a specialty and drop staple articles that everybody is making?" The unexpected reply was, "There is too much competition in specialties themselves." We venture to say that this idea is as new to a majority of our readers as it was to the man who asked the question. But, with comparatively few exceptions, it is too true. The mechanical genius who can at this time devise some novelty which does not come in direct competition with something else capable of doing the same thing or answering the same purpose is a genius indeed. Take small wares, for instance, such as are used in the kitchen. The ingenuity of inventors has been racked to get up numberless devices for beating eggs, for sifting flour, for grinding coffee, &c. Appeals are mutely made by every form of apparatus to the housewife's neatness, celerity, mechanical taste or curiosity, but there are so many articles of such totally different kinds warranted to do the same thing precisely in the most satisfactory way that she is bewildered and is as likely to select the least efficient as the best. The same remarks would apply to mechanics' tools, to personal furnishings, to wagon and carriage supplies, to so-called railway specialties, &c. There was a time when labor-saving automatic machinery began to take the place of toilsome hand labor, when a man of acute perception and mechanical knowledge could easily see an opportunity for the invention of a device which would save labor, economize time, cheapen production and perhaps improve the quality and appearance of an article in quite common use, and the practical development of the thought brought him into prominence as a manufacturer of specialties, and perhaps in time made him wealthy, but to-day such opportunities are few. The ground has been pretty thoroughly covered.

Cheapening Production.

Mechanical talent at this time seems to be turning in a totally different direction. The capabilities of machinery having been very thoroughly developed and opportunities for new applications being discouragingly rare, the most notable achievements making seem to be in the direction of cheapening the production of staple articles. This is the keynote of the manufacturers who are now most successful. The search for specialties is not alluring, as specialty competes with specialty, and consumption is perforce limited. In staple articles, however, there is a constant trade. The manufacturer, therefore, who surpasses his fellows in the cheapness with which he can turn out staple articles of equal quality surpasses them also in securing a large share of the trade and better profits. Never before has mechanical genius so applied itself in this country as now to the solution of the question, how shall the cost of production be further decreased by the introduction of more efficient machinery?

Shop Stories.

THE SOLDERING COPPER.

There are few people who watch a tinner use a soldering copper that are aware how much practice is required to become an expert in its use. It looks so easy to place the copper on the solder, take off a drop, and then apply it to the work, that it would seem that any one could perform the operation. Mr. Jones was one of these credulous mortals. He had often taken his leaky tinware to the tinner to have it made tight, and while the price charged for the work was not exorbitant, Jones thought that by having a soldering outfit he could do the work at home and thus save himself the trouble of taking the various culinary utensils to the tinner. Besides this, there would be quite a saving in expense, as the tinner would charge five cents for applying one or two drops of solder, the cost of which was about nothing. Accordingly, Jones bought a soldering copper, solder, rosin and a small bottle of soldering acid.

With this combination in his possession he felt competent to perform almost any operation in the soldering line. Jones took his small tin shop home with a resolve to show his wife how convenient it would be to have an expert solderist in the house. The family tea kettle had been leaking about the spout for some time, and this article was the first selected for repairs. So Jones set himself down by the stove, placed the copper in the fire and with the other articles near at hand proceeded to proceed. A quantity of rosin was placed where the leak was and then the solder was applied by means of the copper. For some reason the solder failed to stick, and ran off in a most provoking manner. Jones' boy suggested that the tin about the leak should be scraped as that was the first operation the tinner usually performed before commencing to solder. Accordingly, Jones took his knife and gave the place a good scraping and then applied some of the acid, a few drops of which ran down on his pants. The next attempt at stopping the leak was not a success, as the solder would do nothing but bubble and sputter. By this time the family dog had become interested in the proceedings, and drew near to see what was going on. The few drops of hot solder that rolled off the tea kettle struck the dog on the nose and sent him off with howls that were both long and loud.

By this time Jones had come to the conclusion that the tea kettle spout was too complicated in its nature for him to solder, so he next tried his luck at stopping the leak in a britannia tea pot that had been in the family for years, and was considered to be of great value on that account. It would have been better for Jones and the tea pot if this experiment had not been tried, for the metal of which these tea pots are composed is of a kind that does not take kindly to solder, especially when applied by a novice. This fact was clearly demonstrated, for when the solder was applied it not only went through the tea pot but the copper started after it. The result was a hole of great magnitude and a ruined tea pot.

However, Jones would not give up and resolved to show the family that he could solder something. Accordingly a tin pan was selected, and as there was only a hole in the bottom it appeared easy to perform the operation of stopping the opening. Jones applied a drop of acid and then holding the solder in one hand and the copper in the other found there was not a third hand to hold the pan. He accordingly let it rest in his lap and then applied the solder, resolving in his own mind to put on enough so there would be a good job done this time. As the copper was quite hot the solder ran through the hole in the pan, and as a natural consequence came in contact with Jones' leg. This caused Jones to jump and dance more than the dog, and if there was no howling done there were many words said that were unnecessary. The copper and solder were thrown away with much violence, and went through the kitchen window. Jones found his pants were about ruined, as the acid had changed the color and the solder could not be removed. All of this trouble, including a broken glass, was caused by trying to save a little money that should have gone to the tinner. TIN CHIPS.

The repeal of the duty upon block tin is likely to be pressed before the close of the present session of the House. Representative Stump of Maryland, who represents one of the canning districts which suffer by the tin-plate duties, introduced a bill on the 16th inst. to repeal the duty of four cents per pound, which goes into effect on July 1 next. Chairman Springer of the Ways and Means Committee and Mr. Shively of Indiana, who reported the reduction of the duty on tin plate at the last session of Congress, both declare that the repeal of the duty on block tin is of prime importance.

The decline taking place in the export trade of the United States is made apparent in the following comparison of the outward movement of leading staples in January for three consecutive years:

	1893	1892	1891
Cotton	$19,583,638	$28,732,225	$35,638,339
Breadstuffs	13,567,068	30,247,281	9,718,586
Provisions	10,361,319	12,187,846	11,185,583
Oil	2,788,474	3,247,223	3,312,225
Animals	2,139,158	2,831,197	2,294,850
Total	$48,439,657	$77,245,772	$61,549,583

The reduction in wheat exports is most noticeable, and this, although the exporting price from New York was 82 3 cents per bushel, as compared with $1.053 cents per bushel last year.

Papers on file in the Surrogate's office in this city show that the valuation of Mr. Gould's personal property expanded from $500,000, as reported to the Tax Commissioner's office in recent years, to $70,000,000 at the time of his decease.

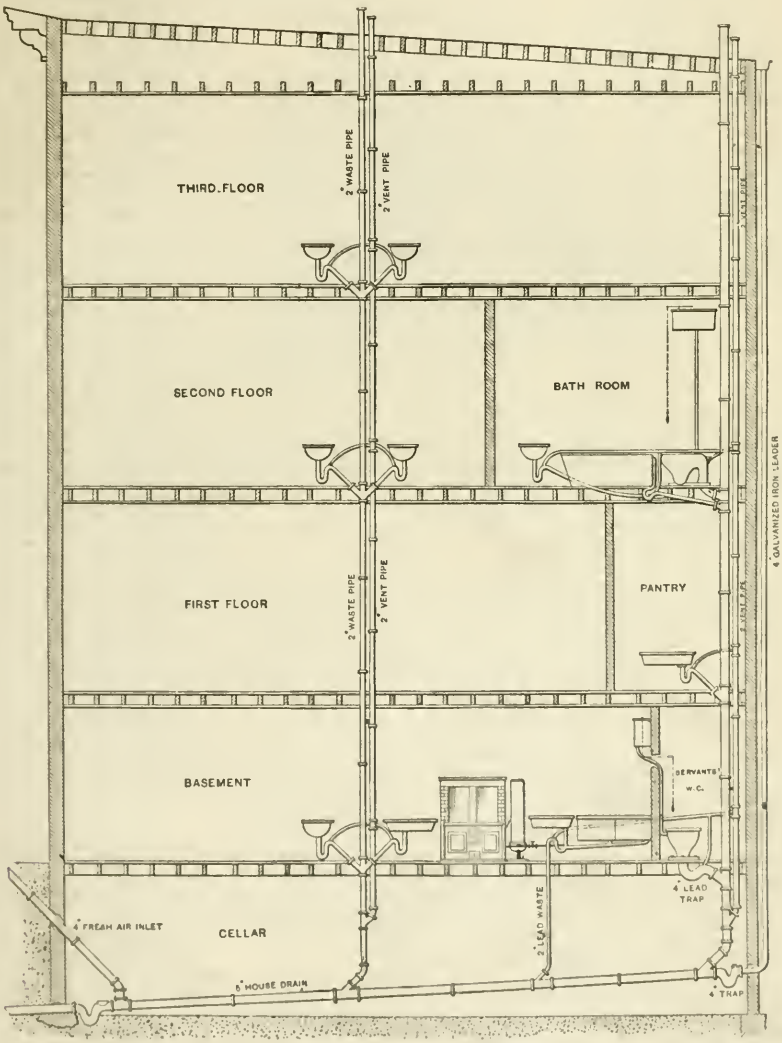
PLUMBING AND GAS FITTING.

Plumbing for a City House.

The demand for plumbing work of an advanced character has become so general at the present day as to place that portion of the plumbing trade who contented themselves with mastering only the mechanical part at a disadvantage. The time when the mere ability to make a joint and run a line of pipe by the readiest methods possible constituted a plumber has departed, and while the same dexterity in handling the tools is still necessary, the new conditions created by the requirements of Health Department standards and the necessity of showing the "reason why" for much of the work now called for inspire a considerable amount of inquiry in relation to the new order of things in the plumbing world. We deem it advisable, therefore, to present an outline of what constitutes the sanitary house plumbing system in New York City.

In selecting the class of house for illustration care has been taken to avoid extremes. The sectional view herewith presented is that of a popular style of private dwelling (a three-story and basement house) which is largely in vogue in the newer portions of this city, and is better calculated on that account to correctly represent the number and arrangement of fixtures throughout the building.

As it is always better to commence at the foundation, the house drain in the cellar and the soil, waste and vent pipes, rising therefrom to above the roof, claim



Plumbing for a City House.

first attention. The diameters of these pipes, respectively, are: The house drain, carried diagonally along the wall, is 5 inches; the vertical line of soil pipe into which the waste matters from bathroom and kitchen fixtures discharge, 4 inches; the vertical line of waste pipe receiving the discharge from basins, 2 inches; while that of the vent pipe, in each case for soil and waste pipes, is 2 inches. The fresh-air inlet pipe, which is set on the inlet side of the running trap on the house drain, is also 4 inches, and all of the iron pipes supposed to be of the grade known as "extra heavy."

THE HOUSE DRAIN.

In setting the house drain in position, care must be exercised that the descent is uniform, and as steep as the depth of the sewer in the street will allow without prejudice to the proper level of the trap at the front wall, the seal of which might be otherwise destroyed. Unless under exceptional circumstances, the house drain should be carried either along the ceiling, properly supported by pipe hangers bolted to the beams, or, as in the appended diagram, along the wall. The opening in the front foundation wall through which the drain is carried to connect with the house sewer outside the building should be larger than the outside diameter of the pipe, and the upper part thereof protected by a slab to prevent possible injury to the pipe by the settling of the building. If the house sewer—that is, the branch sewer from the house wall to the main sewer in the street—is earthen pipe, the iron pipe from the cellar should be carried so far beyond the house line, before connection with the earthen pipe is made, as to avoid all danger of breakage through the weight of area walls or steps above the earthen pipe.

In accord with New York Health Department rules, a disconnecting trap is set on the house drain, inside the front wall, for the purpose of serving as a barrier to the entrance of sewer gas into the pipe system of the house. This is a running or half S-trap, same quality and diameter as the house drain, and furnished with a hand hole hub for cleaning purposes on the inlet or house side. This hand hole is fitted with a gas-tight brass cleaning screw, which can be opened when required for the removal of obstruction from the trap. If the trap supplied is what is known as a double-hub trap—that is, with a hub opening on both the inlet and outlet side, the latter opening should be closed by means of an iron plug calked in in the usual manner. Both of these openings are, however, sometimes utilized, the one on the inlet side for connection for the fresh air inlet, and that on the outlet side as a cleaning hole, but this is a dangerous arrangement, as the latter opening is in direct communication with the street sewer, and if opened in the cellar for the purpose of removing obstructions from the trap, sewer gas, during such removal, will have unrestrained entrance into the building, and the trap as a preventive will become worse than useless.

The house drain should be well supported, and when carried along the cellar wall, as in the diagram, a pipe hook should be supplied for every 5-foot length, so as to relieve the joints from strain, and it is advisable where vertical pipes discharge into the house drain to have a brick support built at that point for the same purpose. The vertical or rising lines of soil and waste pipe should always discharge into the house drain through Y-branches and one-eighth bends, and not as sometimes done through T-openings. It is also good practice to have rain leaders discharge into house drains, so as to aid in cleansing them. In the sketch herewith the 4-inch galvanized leader at rear of building is so arranged that the roof water is utilized in this way, a 4-inch running trap being set inside the rear wall at junction with drain pipe to prevent the foul air from escaping up through the leader and entering windows contiguous thereto. The leader trap should be set with the hand hole for cleansing on the leader or inlet side and should also be provided with brass cleaning screw.

Yard and area drainage has to be provided and the surface water to be discharged through the house drain, the branch drains to be trapped inside the cellar before they enter the house drain. If the yard level inlet permit, the yard drain can connect with the leader at the bend where it enters the wall, in which case the leader trap will answer the double purpose. If the yard drain has to be brought into the cellar from some other point, it must be independently trapped before it connects with the house drain, and the same rule is applied to the front area drain, which must be trapped and discharged into house drain on the inlet side of trap at front wall. By this arrangement the roof water and the surface water of yard and area are utilized to keep the house drain properly scoured. Drains with perforated plates are set in the yard and area drain pipe.

FRESH AIR INLET.

The fresh air inlet pipe is inserted in a T-opening set in main drain on house side of main trap. It is intended to provide a current of fresh air for the pipe system in the building, and with this object in view it is carried, in this city, to the sidewalk near the curb, and the opening, which must be at least 10 feet from nearest opening, is covered with a metal grating. The hub of the T in the cellar, into which the inlet pipe is calked, should invariably be set perpendicularly. Sometimes it is set in the side of drain pipe, or horizontally, which is not good practice, as in the latter case the sewerage, if checked in its flow at the trap on main drain, will naturally turn aside into the inlet branch and by clogging the opening render it useless as a passage for fresh air. This cannot occur when the T is set in an upright position. And inasmuch as the regular flushing of the main drain will have little effect in cleansing the inlet, a recurrence of stoppages will in time render the inlet pipe of no value. In country places, however, better facilities offer for making the fresh air inlet pipe useful, and care should be taken that it is not omitted from the house plumbing system.

VENT PIPES.

In the diagram which we present it will be noticed that the vent pipes which are intended to vent the traps in the vertical soil and waste pipe lines, instead of starting upward from above the traps of the lowest fixtures, in each case they commence below the lowest fixture, starting from a Y-branch connection with the soil and waste pipes respectively. This is a rule adopted by the Health Department to afford means of disposing of the rust from the inside of the vent pipes, which is liable to settle in the lowest trap on the line. This, in many cases, is but a 2-inch trap, which would readily become choked up. Under the new arrangement the iron rust or other matter falling through the vent pipe, instead of lodging in a trap, is carried down into the house drain through the Y on soil and waste pipe and is carried away with the sewage into the street sewer. This arrangement of the vent pipe, by providing a foundation, as it were, makes the vent pipe firmer than under the old method and on the whole is considered a desirable one.

FITTINGS ON VERTICAL LINES.

In arranging the several fittings on the vertical lines it will be seen that separate branch openings are always called for in the case of water closets unless where space is limited. For instance, in the bathroom, as illustrated, a 4-inch Y-branch is provided for water closet and a 2-inch separate opening for the bath and basin waste. If circumstances, however, prevented the insertion of the 2-inch Y-branch in the vertical soil-pipe line, it would be permissible to discharge the wastes of the bath and basin into the lead soil pipe of water closet provided the discharge pipe was made to enter on the outlet side of the water-closet trap, not otherwise.

TESTING PIPES.

The testing of the pipes is something which should never be overlooked. The methods most in use are by water and air, while some of the more advanced claim that the smoke test is the best. We will confine ourselves to the two former methods, and will first deal with the water test. As the success of the test depends on how the joints are made, the plumber must bear in mind that a large quantity of oakum put carelessly in the hub and molten lead indifferently calked in will not resist the pressure of a column of water in the pipes. The joint must be made by using just sufficient oakum to form a bed for the lead, and ramming it so tightly home as to prevent any of the lead forcing its way through the joint into the pipe. For every inch in the diameter of the pipe 12 ounces of lead are required, all of which should be poured into the joint at once, as it is of very questionable advantage to make a second pouring of hot lead over the cold lead in the joint. For a 2-inch joint in iron pipe 1½ pounds of lead are required, for a 4-inch joint 3 pounds of lead, and for a 5-inch joint 3¾ pounds. The size of the ladle to be used will therefore be readily understood by the plumber. It is very desirable that the entire system of soil, waste and vent pipe, both lead and iron, should be tested at once. This can be done by securely plugging the opening of the house drain on the outside of the building before it is connected with the sewer, capping all the lead wastes before attaching the fixtures and then filling up the pipes to the roof. If the test is satisfactory every joint, both those of the iron pipe and the ferrule work, may be relied upon as proof against sewer gas, while if there is weakness in any joint or a defect in any of the pipes it will be readily detected. If from inability to procure water the air test is applied, the plugging is to be done in the same way, except that a piece of gas pipe is inserted in the plug in one of the hub openings and either a pressure gauge or a mercury gauge is attached. The air pump, connected with the gas pipe by a rubber tube, is put to work and air pumped into the pipes until the required pressure to the square inch is obtained. In determining this pressure preference is given to the mercury gauge, the pressure being indicated by the hight of the column of mercury in inches, each inch being considered equivalent to ½ pound pressure to the square inch. When the pressure test was first introduced the New York Health Department required 10 pounds, equal to a 20-inch column of mercury, but this extreme requirement has been modified and a 5-pound pressure test is now considered satisfactory. If a joint is suspected of leaking during the air test an application of soapy water will readily enable the plumber, by the appearance of air bubbles, to locate the exact spot where the application of the calking tool is required.

SETTING FIXTURES.

The fixtures represented in our diagram do not need much reference, if we except those in the bath and kitchen. In setting these in position it is desirable that each trap be as near as possible to its respective fixture, and the vent pipe from the crown so inclined that water of condensation will drain into the trap. Provision should be made, when setting up the vertical line of vent pipe, that the T openings to receive the trap vents are set sufficiently high to secure that incline without having to set the trap further from the fixture than good practice warrants, in order to secure the desired result.

The water closet in bathroom, which is presumably of porcelain, the trap and bowl in one piece, needs careful setting. The soil-pipe branch from closet to 4-inch opening in vertical soil pipe is lead, not less than 6 pounds to the square foot (the Health Department calls for 8 pounds) and is flanged over at bathroom floor level on a brass floor plate having a 4-inch opening, the edges around which are usually countersunk to admit of the lead

flanges. The closet is set on this floor plate, a rubber gasket or a cushion of red lead putty being set between the closet and the plate, both of which are then bolted together. Some of the floor plates have the edge of the opening in plate beveled instead of countersunk, in which case the lead soil pipe is not flanged over, but is cut flush with the plate and the beveled space filled with solder, uniting floor plate and soil pipe in an effective manner.

The servants' water closet is a flush rim hopper set in a compartment entered from the yard. The 4-inch lead trap, properly vented, is under floor and discharges into soil pipe in cellar. The cistern for flushing is set in the kitchen, over the washtubs, the chain and pull being brought through the wall. This is done to prevent the water in cistern freezing, which would be almost certain to occur if set directly over closet bowl. One trap suffices, under Health Department rules, for the sink and the washtubs in the kitchen, the 2-inch lead waste pipe from the tubs discharging into the sink waste pipe above the trap on the inlet side, which in turn empties itself through a Y-branch into the house drain in cellar.

Safes under fixtures and the safe wastes leading to the cellar are omitted from the diagrams, but plumbers, as a rule, know all about them.

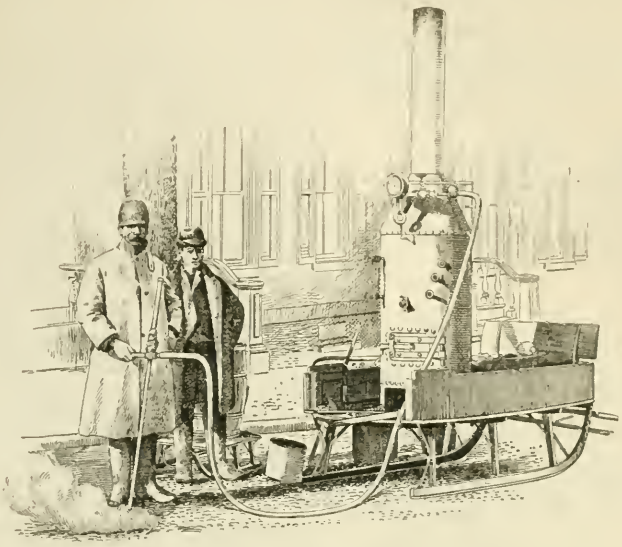
PIPES ABOVE ROOF.

In extending the vertical lines of pipe above the roof care should be taken to avoid the use of offsets, owing to the danger of lodgments of snow, and the resultant danger of being closed up by the formation of rust. The pipes should be extended full-bore straight through the roof—the hight of the extension of the soil (or waste) pipe and the vent pipes terminating at different levels, so as to avoid the consequences of down drafts—that is, the foul air discharged from one pipe being carried back into the dwelling by the other. Until recently the Health Department required all pipes 4 inches or more to be increased 1 inch in diameter above the roof, and no roof extension to be of less caliber than 4 inches. At the present time no enlargement of pipes above the roof is called for.

Thawing Frozen Water Pipes.

From W. C. V., *Schenectady, N. Y.*—It may be interesting to some of the readers of *The Metal Worker* to know how we fight the hold "Jack Frost" had on our water service pipes, and in fact on our water mains. While my men were at work on a frozen service a short time ago I thought it might be cooling during the warm weather next summer to look at a picture of the men at work thawing the ice out of a service some 5 feet below the surface of the street. I brought out my camera, and with a $6\frac{1}{2}$ x $8\frac{1}{2}$ plate took the picture, of which I send you a copy. You will notice that there is very little snow on the ground, a fact we became well satisfied of when we moved our outfit to another place. We have our boiler on a sleigh; and the only other part of the outfit, besides the usual boiler fixtures and small tools, is the pipe that we use for carrying the steam to the seat of the trouble. This is a piece of $\frac{3}{8}$-inch iron pipe about 6 feet long with a $\frac{3}{4}$-inch cross at one end. In this cross we have two pieces of $\frac{3}{4}$-inch pipe for handles and a piece of $\frac{1}{4}$-inch pipe to connect to $\frac{1}{2}$-inch steam hose that is in turn connected to the boiler. To use it we turn the steam on and start the pipe in the ground, and through the frost it goes in a few minutes. We usually start at the "goose-neck," as the connection to the main is called. The pipe here is about 1 foot above the remainder of the service and we often start the water running by letting the steam warm the ground up well at this point, by leaving the pipe in the ground for a time, after we have found the service pipe by feeling for it with our steam pipe. The picture will, I think, give you a good idea of the work without any further explanation.

This thawing out was a very common scene with us in January. A little while ago we had our boiler at work on a service when there were four other boilers at work on the same block. Since then I have seen five boilers working on a frozen main for the Water Department not 10 feet apart.

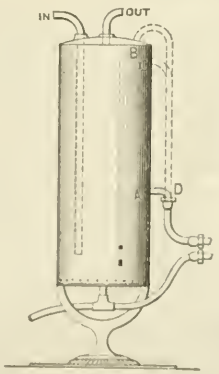


Thawing Frozen Water Pipes.

One advantage of this manner of thawing is that the ground around the pipe is well warmed up and is not so liable to freeze again during the winter so as to stop the water. This cannot be said of many other ways that the trade do the work, more especially from the inside of the house.

Change of Connections from a Kitchen Boiler.

From C. C., *Chicago, Ill.*—How could I improve the efficiency of a 50-gallon hot-water boiler so as to facilitate the rapid heating of at least a portion of, if not the entire, water contained in it? My case is this: A customer of mine recently moved into a house, in the kitchen of which a 50-gallon boiler is set up and connected with the usual hot-water piping found in most houses to sink, bath, &c. The tenant who lived in the house before, and whose range I also connected to the same boiler, had no difficulty in getting all the hot water he required. He, however, had a large No. 9 range, with a large water back. The range of the new tenant is somewhat smaller, and in my opinion should be considerably larger to perform the task required of it. He does not care to buy a larger range, but wants me to fix the matter so as to help him out if possible. To do this I propose to change the hot-water return from the range from where it enters the boiler now at A, to where it is shown at B, by the dotted outline of the pipe and stop up the hole at A. This arrangement I think will do the business; am I correct? I would like to have your opinion on this proposed change in the pipe.



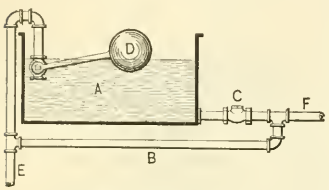
Change of Connections from a Kitchen Boiler.

Answer.—The expedient suggested by our correspondent will in all probability help him out of the difficulty. We would offer the suggestion, however, that it would be a better plan to connect the inlet at the joint C instead of at B, say 6 inches or 8 inches below the top of the boiler. This plan of putting the hot-water connection at the top of a boiler is a poor one at its best. It is true that in order to obtain hot water quickly the arrangement does well enough, but as a matter of fact it does not offer the ample reserve supply of heated water that the rational and well-tried mode of connecting the hot water return at A does. For this reason, the point C is a far better one for the purpose than B, at the top of the boiler. The supply of heated water taken in at point B would be exhausted in very short order, while the amount in reserve taken in at point C would be heated almost as quickly and would provide a better supply. Another point to consider is that the time required to heat the water in the whole boiler (if the hot-water feed is taken in at the top) will be considerably longer than if the connection were made at A. An improvement on the arrangement as suggested by our correspondent would be to make the proper pipe connections

with two inlets, one at C and the other at A, with a three-way cock at D, so that either could be shut off when it would be desirable to use the other.

Supply-Pipe Arrangement.

From J. T., *Brooklyn, N. Y.*—Inclosed I send sketch of an arrangement of supply pipes which I think would relieve "J. P.," whose letter appears in *The Metal Worker* of February 11. The principle is as follows: While the pump is working he would get at least 5 pounds pressure on the pipe B, which would close the check valve C and when the float D would close he could leave a little steam



Supply Pipe Arrangement.

on the pump that would keep just pressure enough on the discharge pipe E to supply the emergency. This would be done only at that particular time of day and he might be able to adjust the speed of the pump between the hours mentioned to keep the water level at a good point, and while it would only be doing the actual work required, the pump would give an extra pressure on the supply pipe F.

Bursting Pipes by Frost.

From S. H. B., *Geneva, N. Y.*—I have read with much interest the accounts of experiments in *The Metal Worker* of February 11, in regard to the bursting of water pipes by frost. In the latter part of the article the author says he did not experiment with lead pipe. I cannot say from actual experiment, but from what I have seen in my own experience as a tinsmith I believe that lead pipe is much more liable to burst than iron pipe. There is perhaps no tinsmith or plumber who has not been called upon to repair a lead pipe and found it enlarged at some point and burst open lengthwise about an inch. This could not have been done in this manner by ice forming at this point, but must have been caused by the pipe becoming in some way stopped at each side of the opening, and then ice continuing to form from one or both directions toward this point. The result would be the pipe must enlarge, which it would do at its weakest point, and the more it enlarged the less would be the resistance there, so that all the expansion would be confined to a space of about an inch in small pipes. The same result would occur if the water between the two plugs was warmed before the stoppage was removed from either side. In lead pipe the rupture must occur with some kind of an explosion, as the opening is usually found to be ¼ to ½ inch in width. I never saw a lead pipe burst by the direct pressure of ice formed or forming within it, and do not believe it would be possible for it to occur.

Electricity and Water Pipes.

Electrolysis of water pipes, says *Fire and Water*, was the principal topic of discussion at the last meeting of the New England Water Works Association, held at Young's Hotel, Boston, January 11, 1893. Charles H. Morse, electrician, of the city of Cambridge, gave an account of the result of his observations and opinion regarding the operation of the electric current in its effect upon water pipes in that city. He states that in some cases lead pipe had entirely disappeared by the action of the electric current, and the same result had followed in the case of iron, galvanized iron, brass and rustless pipes where they had been substituted. Mr. Morse claims that corrosive action takes place where the current leaves the pipe and not where it enters it. The electric current which occasioned the trouble came from the operation of electric street cars. The experiment of reversing the electric current was tried, and also soldering heavy wires to the pipes, as a means of conducting the current back to the power house. This last experiment obviated the trouble to a great extent, and by reversing the current and using the wire connections of the pipes as a medium, the trouble was still further reduced. A further discussion and inquiry revealed the statement that the return wires between the rails were too small to carry the current back to the power house. In some instances these wires had disappeared. It is intimated that if the water pipes could be insulated no electrolytic action would take place. With what information we have before us upon this question, it is quite apparent that if the return wires, now said to be too small for the purpose designed, were made larger, there would be no need of providing return connections from water pipes or reversing currents. Motive power by electricity seems to be an established fact; at the same time, corporations enjoying franchises for the right to use electricity as herein mentioned should be compelled by law to protect the water service pipes. It is laudable to consider primarily cost of construction in connection with maintenance; at the same time, false economy results in double expense. It will be cheaper in future for electric railway corporations to use the best materials in construction in first application. When suits are brought against the city for permitting private property to be injured through a franchise granted by the city, perhaps municipal officers will be more careful and be willing to employ competent electric engineers to pass judgment on all plans proposed for construction of electric railways. There is much to be done in the way of developing practically the electric science in connection with motive power

Plumbers' Examinations.

From G. G. U., *San Francisco, Cal.*—Will you kindly give in the columns of *The Metal Worker* a list of the questions put to plumbers by the examining board in New York City. Are they the same all over the States? Also, can a plumber do jobbing in New York without passing an examination?

Answer.—There is no regular list of questions propounded by the Examining Board of Plumbers in New York, as far as we can learn, because practical plumbers know very well that there is something more than the ability to answer technical questions required of applicants for license to do plumbing work. There are very few trades so exacting in their demands on the intelligence of the men pursuing them as that of plumbing. Difficulties are continually presenting themselves which call for good judgment and a knowledge of natural laws and their proper application in the solution of such difficulties. The New York Board of Plumbing Examiners has only recently organized, but for some years past the License Committee of the New York Master Plumbers' Association gave attendance gratuitously, once a week, at the office of the Department of Public Works, and subjected applicants for plumbing license to a very rigid examination. The applicant would be required to illustrate, by drawings, how he would run his soil and waste pipes to suit certain conditions of the job or the peculiarities of buildings; if pumps were to be used and obstacles to be encountered, what he would do to get them to work satisfactorily, if in the piping of a house for hot or cold water service deviation from usual methods was unavoidable, how he would adapt himself to circumstances—in fact, every problem necessary to test his ability to undertake plumbing contracts would be proposed by one or other of the committee in the exercise of his judgment, and a verdict would be rendered on the ability of the applicant to satisfactorily answer the problems. We are uncertain as to the practice in all the States, but we know that there are legal restrictions in Maryland and Pennsylvania. In the former State a plumbing law, resembling the New York law of 1892, has been in force for several years, the members of the examining board being appointed by the Governor.

In Pennsylvania there has been in operation also for several years a general law, the execution of which is in the hands of the boards of health of the respective cities, and the scope of which embraces the qualifications of plumbers.

The ordinances adopted in many cities where there is no State law which bears upon the subject frequently provide for examination into the fitness of applicants for plumbing licenses, and it is likely that the line of investigation pursued is largely a matter of judgment on the part of the examiner or examining body. In relation to the last inquiry, a plumber doing business in New York City after the first day of March, 1893, without having been examined by the examining board, and a license duly issued, does so in violation of law, and is subject to the penalties provided in the act establishing the board. If he should succeed in evading it, and do some job of plumbing work, and the party for whom he did the work afterward should refuse, on some pretext or other, to pay for it, the plumber, it would seem, would have no redress, as his suit, if he brought one, would be thrown out of court on the ground that not having complied with the license law he would have no standing in court.

TRAPS AND VENTS.

IT IS ALLEGED, says a foreign exchange, that some one has obtained a patent on a device for preventing the bursting of water pipes during the cold weather. The inventor, so it is said, has ascertained the amount of expansion to be looked for when water freezes, and has perfected a composition which contracts in equal proportion from cold. A thin rod of this latter is placed inside the pipe, and experiments show that no amount of freezing can make the pipe burst. The trouble is that the water may freeze first where the contracting rod is located, and after it is inclosed in solid ice burst out somewhere else. It often happens that a pipe freezes in spots, the remaining liquid contents taking up expansion until they too get below the expansion temperature just before freezing. To work properly, the rod would have to run from end to end in a pipe.

THE NEW plumbing board of Kingston, N. Y., consists of Henry E. Wieber, Bernard Loughran, John F. Halloran and E. B. Codwise.

IN THE COURSE of his address at the third annual convention of the Connecti-

cut State Master Plumbers' Association, held at New Britain, Conn., February 9, President Lyman D. Mills of Middletown said: "One of the most important steps this association could take at this time, or perhaps in the near future, would be to establish and maintain a trade school, for the education of apprentices, for by this means only are we assured of the plumber of years to come possessing the knowledge necessary for him to take his stand as a sanitary expert and to engage the confidence of the public."

H. C. MONTGOMERY, Brainerd Building, Cleveland, Ohio, issues an illustrated and descriptive catalogue of some of the lavatory specialties which he manufactures. The publication contains but a few pages, is neatly printed and the cuts are carefully made. The first few pages show a number of different forms of the Elite cast-brass traps. A pleasing effect is given by the gold bronze in which some of the illustrations are printed. The Elite waste and overflow and the Elite cast-brass lavatory brackets are noticed later in the pamphlet.

THE RAYMOND LEAD COMPANY, Lake and Clinton streets, Chicago, are now supplying plumbers with the American Plumbers' Supply Company's ebony gloss soil, which is guaranteed not to sour, ferment or become rancid, nor to rub, peel or burn off. It is put up in paste form in packages of 1 pint to 5 gallons.

THE HENRY HUBER COMPANY, New York, manufacturers of sanitary specialties, have moved their Chicago office and salesroom from 82 Dearborn street to 231 East Kinzie street, at which place they will remain until more commodious quarters can be secured.

P. W. HUDNER of Hudner & Regelsberger, St. Paul, Minn., was in Chicago for a few days buying plumbing goods for a large contract which the firm have in Duluth.

O. D. PECK, of Peck Bros. & Co., manufacturers and jobbers of plumbers' supplies, 259 Wabash avenue, Chicago, has left the city to attend the annual meeting of the stockholders of Peck Bros. & Co., to be held at New Haven, Conn.

THE DECECO COMPANY furnish through the Walcot Hurlbut Company, manufacturers and jobbers of sanitary specialties, 175–177 Lake street, Chicago, 77 Dececo closets for the Windermere Hotel, and 18 of the same closets for the Elsworth building.

ACTING under the provisions of the State Plumbing Law, Mayor Price of Jamestown, N. Y., has appointed to the board for plumbers in that city, William Swanson, journeyman plumber, Jonas Woodhead and George H. Chatfield, master plumbers, and J. Dana Littlefield, and Jonathan T. Pennock, members of the Board of Health.

Gathering of the Classes of the New York Trade School.

The delightful social gathering of the day and night classes of the Trade School on Tuesday evening, February 21, was a popular and profitable one. As the students and visitors entered the new auditorium there were many complimentary things said about its attractions and handsome appearance.

The evening's programme was conducted somewhat informally to subtract conventionality and add the charm of warm-hearted entertainment. That this was successfully done was attested by the hearty applause, eager interest and pleasant social intercourse during the rendering of it as well as by the farewell expressions of enjoyment.

The opening piano solo, played by C. F. Rudenauer, was followed by a humorous recitation from L. H. Hallen, which merited an encore. As soon as the name of Miss Radcliffe was mentioned (it will be remembered she sang at the last gathering) applause came from all parts of the auditorium. With remarkable effect on the audience she sang "Come Unto Me." Miss Krider played the accompaniment with skill. Then H. E. Claflin, in behalf of the Day Plumbing Class, presented to the singer an emblematic stand of beautiful flowers.

One of the principal events of the evening was the well-received address of John Byrns on the subject, "Duties of the Artisan Citizen." The thoughts uttered were useful to the young artisan, and his earnest delivery did not exceed the earnest attention given the speaker. After Mr. Hallen rendered a piano solo one of the Trade School's friends, Edward Murphy, spoke a few minutes on the institution's history and its struggle to progress and fame.

Messrs. Worth and Whelpley, in their harp and guitar selections, were heartily applauded and encored.

The announcement that Mr. Heatherton of the *Plumbers' Trade Journal* was present with practical suggestions for the students called forth applause.

C. E. Bevington, editor of the *Sanitary Plumber*, was called on and made a thoughtful address that kept the attention of his hearers. Just then came the conversational period, with light refreshments and several banjo selections. J. Stanly Thomas then proceeded with the programme and stated that Miss Radcliffe would sing by request the hymn "My Faith Looks Up to Thee," in a duet with Mr. Newman. At the close the plumbing class scattered flowers before the platform as an evidence of their appreciation.

It was the good fortune of the Auchmuty Musical Society, under whose auspices the gathering was held, to have secured the Rev. Dr. Rainsford to address them. Close attention was given as he eloquently presented striking thoughts in the most liberal and sympathetic manner.

James Muir of the Master Plumbers' Association said a few congratulatory parting words, and the evening was brought to a close with conversations and examining specimens of student work displayed in the auditorium.

Weekly Prize Competitions.

$25.00.

FOR MORE THAN six months Weekly Prize Competitions ($10) have been an interesting and useful feature of the *Pharmaceutical Record*, a journal issued from this office and devoted to the interests of the drug trade. These weekly competitions have related to a variety of technical and business questions of interest to druggists, and have brought out a large amount of information of much service to the readers of that enterprising journal. In view of the success of this feature we have decided to announce a similar series of Weekly Prize Competitions on questions of interest to our readers, and invite a general participation on the part of the trade. As the object of these competitions is to obtain information which will be of practical service to our readers, and to discuss questions in which they are interested, we shall esteem it a special favor if any in the trade will suggest subjects for such competitions, which, if deemed suitable, we shall take pleasure in using.

In each competition there will be three prizes—a first prize of $12.50, a second prize of $7.50 and a third prize of $5. The prizes will be awarded for the answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. These competitions are open to every one, and it is hoped that there will be a general response from business men. Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers to the different questions will be favorably regarded as meeting the purpose for which these competitions are announced. We shall have the privilege of publishing any or all of the contributions received.

Prize Competition No. 13.

SUBJECT:

The Best Method of Changing a Credit Into a Cash Business.

It is generally conceded that an all cash business is preferable to one part cash and part credit, or to an all credit business. The object of this competition is to draw out practical suggestions for making such a change, and touches on such points as these:

Whether the change should be made on a certain announced date, or gradually;

How to acquaint customers with the proposed change, whether personally, through circulars, or newspaper advertising;

How to provide against shrinkage of sales under the new system; and

Whether lower prices can be advantageously offered as an inducement to purchase for cash.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

Replies are to be received not later than March 18, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 13.

Our Prize Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 4. Closing February 25.
Suggestions as to Improvements in Putting up Goods.

No. 5. Closing March 4.
A Method of Securing a Reliable and Prompt Delivery of Goods.

No. 12. Closing March 11.
Arrangement of Pocket Cutlery.

No. 13. Closing March 18.
The Best Method of Changing a Credit into a Cash Business.

Another subject will be announced in our next issue.

WORLD'S FAIR NOTES.

Withdrawals of Exhibitors.

More interest is now being taken in the stories current of the wholesale withdrawal of exhibitors than in any other subject connected with the exposition. These have been published in a way to convey the impression that general dissatisfaction exists with the allotment of space, the proposed system of awards, the regulations governing the installation of exhibits, &c. If these stories were but half true the public would be justified in believing that the exposition is on the eve of a flat failure. The troubles which have arisen, however, are greatly exaggerated. Prominent piano manufacturers have announced that they intended to make no exhibit, as they object to the system of awards which has been adopted, but other applicants for their space are so numerous that the piano manufacturing industry will certainly be well represented. It is a question whether the dissatisfied manufacturers will not injure themselves by the course they have taken. As to other cases of dissatisfaction these do not seem to cover exhibitors by classes, but only individuals. The writer has had occasion the past week to investigate a number of them. A few of the results of his investigations will be given.

A large manufacturer of machinery, who determined that he would not complete arrangements for an exhibit, stated that he had been refused adequate space. He had applied for 4000 square feet and was allotted but 3000, which was altogether too small. In explanation of this case, Chief Robinson of the Machinery Department points out that the entire space reserved for domestic machinery comprises 220,000 square feet, of which 20,000 feet will be needed for passages, leaving 200,000 feet for exhibits. The largest machinery manufacturers have been awarded 3000 square feet. This would divide the entire space among only 66 exhibitors, but fortunately all applicants were not equally prominent, there being some 1300 in all. The others have been able to secure space by reducing individual allotments as much as possible. It is regrettable that any prominent manufacturer should elect to be absent from this great display of American machinery products, but it is hard to see how more space than that assigned could have been granted without doing very great injustice to other deserving applicants.

Some manufacturers state that they have decided not to exhibit because their allotments of space were not made in time and they cannot now prepare a creditable exhibit. This could not be helped. Perhaps no previous World's Fair had such an overwhelming application for space, both as to number of applicants and space desired. The whole of Jackson Park would have had to be roofed over to accommodate them if all had been accepted and every one had been given the space designated. This was manifestly impossible, and the problem then arose how to treat the applicants. Their cases were passed upon critically, and, while some were rejected because their exhibits would have had no value in a World's Fair, the others were assigned the best space and the best positions available. Those who applied after the published date for closing the consideration of applications were not rigidly barred out, but their applications were filed in order and when an opportunity arose through the declination of some exhibitor previously favored the late comers were given a chance. In this way space will continue to be alloted up to nearly the opening of the exposition. No fault can be found with this, but, on the contrary, the dilatory applicant should consider himself fortunate if he gets space in that way.

Chief Skiff has had the same difficulties to contend with in Mines and Mining. A symmetrical plan for the distribution of exhibits by groups has been followed in his department. This, however, brings some exhibitors in galleries who prefer to be on the main floor and *vice versa*. Some are in corners when they prefer locations near main entrances or along principal passages. Some think their exhibits belong properly in Machinery Hall or in the Transportation Building, instead of the Mines and Mining Building. Individual dissatisfaction depends so largely on temperament that it is not strange that there have been cases of withdrawals, because all men are not blessed with good nature, and some men will insist on having their own way in defiance of necessary rules and regulations.

Preparations for Exhibits.

Machinery Hall would, ere this, have been a very busy scene, with exhibits being rapidly installed, if the winter had not been so severe. Not only were men unable to work for long periods, on account of the intense cold, but the roofs proved inadequate to the burden of snow and ice. Skylights gave way here and there, and, while the damage done was not at all serious, yet the admission of snow and rain deterred exhibitors from installing valuable machinery. About half the foundations for the engines are ready and some of the smaller engines are in place, but the weather will have to be a little more propitious to enable roofers to repair damages before the large engines are erected. There was another fall of nine inches of snow in the Northwest on Friday. Thus it goes. Installation under such circumstances is out of the question.

The Mines and Mining Building is in much better shape, being smaller, and therefore better roofed. Some 32 carloads of exhibits were on the floor on the 16th, which is in advance of any other department. The unpacking and arranging of these exhibits is being pushed vigorously. Many States will make exhibits as States, and all of these report their work in excellent shape. The technical library in this building will perhaps be the finest ever collected in connection with mining and metallurgy. The problem now confronts Mr. Skiff how to get the necessary room to display it properly.

An Unwise Rule Rescinded.

Members of the Council of Administration passed a rule on the 16th that exhibits and material intended for World's Fair buildings should enter Jackson Park without charge, provided the same were conveyed at the cost of the exhibitors.

There was a great hubbub at the Sixty-fourth street entrance to the park that morning when a score of wagons drew up waiting for admission to the grounds. According to a rule recently promulgated by Mr. Holcomb, General Manager of Transportation, cartage was to be charged for at the rate of 6 cents per 100 pounds. Commissioner Wermuth of Germany and representatives of Great Britain, New South Wales and France called on Director-General Davis to protest against the charge being exacted. Colonel Davis immediately applied to the Council of Administration, asking fair play for the foreign government representatives. The council decided that the charge of 6 cents per 100 pounds should not be exacted upon the entrance of material which might be carted to the several buildings at the expense of the intending exhibitor.

This decision on the part of the Council of Administration did not meet with the approval of Director of Works Burnham. Mr. Burnham thought that a toll should be exacted for the use of the exposition roads. He saw no other way of equitably providing for the expense of building them. The council, however, thought differently.

A Salt Water Pump.

At College Point, L. I., is a remarkable pump, which has been constructed to keep the supply of salt water for the fisheries exhibit of the proper quantity and quality. Two similar machines have been tested and operated successfully. When the fisheries exhibit was planned one of the puzzling details was how to secure a continuous supply of salt water for the sea fish and how to keep it free from contamination. A means of transporting the water right from the ocean by evaporizing it and subsequently restoring it was devised. Then a special pump had to be made, as the water must be used over and over again, and that with as little loss and contamination as possible. No ordinary pump can be used for salt water without the metals being corroded and acids injurious to animal life being formed. The new pump does not differ much in appearance from any ordinary machine of its kind, except that no metal beside a few nickel bolts can be seen. Inside, however, there are many differences, the valves, pistons, rings and springs all being made of hard rubber. In this way things have been arranged so that the supply of sea water will be constant and pure in the lakes from the opening of the fair to its close.

Relics from Yucatan.

One of the most interesting displays that will be seen at the fair will be that made within the "Ruined Palace of Mitla" by the department of ethnology. Prof. Edward H. Thompson, who has been consul at Merida for eight years, has prepared papier mache molds of the ancient sculptures found in the deserted cities of Yucatan, and 30 cases of these molds have already arrived at the park.

The ruins of Uxmal will be reproduced on an extensive scale, and among them will be a perfect *fac simile* of the temple and figure of the god Kukulkan, or the great feathered serpent. The body of the serpent is wrought in the stone work all around the building, and this will be represented entire. The original materials were principally marble and coarser varieties of limestone, and the work shows that the ancient Yucatecos possessed great skill in mechanical workmanship, though their industrial arts were but poorly developed.

The great forest or jungle covering the supposed kingdom of the ancient Mayas is about the size and shape of Ohio, and covers portions of Yucatan, Guatemala and adjacent Mexican States. There once lived in that area from 5,000,000 to 10,000,000 people, according to Captain Del Rio, who explored part of it late in the last century, and Captain Dupaix, Brasseur du Bourbourg, A. Le Plongeon, and other recent explorers. The ruins of their cities are now spoken of as buried. They are in fact buried only in dense masses of tropical growth, of which the thorny shrubs and parasitic vines present the greatest obstacles. One of the finest reproductions by Professor Thompson will be that of an arched gate of the ancient palace of Labra, which was literally chopped out of the jungle.

Miscellaneous.

From the Watervliet Arsenal gun shops at West Troy, N. Y., will be sent for exhibition six guns of different calibers and sizes. They will include a 12 inch gun, a 10-inch gun, a 7 inch howitzer, a 5 inch siege rifle, a 3.6-inch rifle and a 3.6-inch mortar. The largest and the smallest gun will be mounted alongside of each other. The largest is 37 feet long and weighs 52 tons and the smallest is 2 feet long and weighs 224 pounds.

A representative traveling man may be elected to a position on the Board of Directors of the World's Fair. Charles W. Clingman is receiving substantial support for the place, and, it is reported, has a good chance of election. He is making an effort to get proxies from the stockholders by means of a circular letter.

The Indiana Senate on the 16th decided to appropriate $75,000 for the Indiana World's Fair Commission. The House committee has recommended only $25,000, but it is believed the House will concur in the Senate's action.

The South Dakota Senate on the 16th passed the House World's Fair bill, with amendments increasing the amount to $65,000 and creating a commission to be appointed by the Governor.

Advices have been received of the arrival in New York of 41 cases containing parts of the great locomotive exhibition to be made by the Great Western Railway of London, Eng.

OBITUARY.

LYMAN WETMORE COE.

The Hon. Lyman Wetmore Coe, president of the Coe Brass Mfg. Company, died suddenly at his home in Torrington, Conn., on February 9, aged 73 years.

Lyman W. Coe was the son of Israel and Nancy Wetmore Coe, and was born January 20, 1820, at Torrington Hollow; received a common school education, and attended the high school at Waterbury, Morris Academy and the school of W. W. Andrews of South Cornwall. He began as a clerk in Waterbury, where he remained until the spring of 1834, when he went to Wolcottville (now Torrington) and engaged in the store of Wadhams, Coe & Co. for two years; then went to Terryville, into the store of Lewis McKee & Co., merchants, and the first cabinet lock manufacturers in the country; was with them three years in all, being at home and connected with the manufacturing at the brass mill one year. He left there in the spring of 1841 and was appointed secretary of the Wolcottville Brass Company, which office he retained until the summer of 1845, when he resigned. He then took charge of a brass-wire mill at Cotton Hollow, which then belonged to the Waterbury Brass Company, and in the spring of 1846 was appointed secretary and treasurer of the Waterbury Brass Company, and the business at Cotton Hollow was removed to Waterbury. He was connected with this brass company from its formation in 1845 to May, 1863, and during that time was its general financial and business manager.

In the spring of 1863 he resigned at Waterbury and bought all the stock of the Wolcottville Brass Company and formed a new company under the name of the Coe Brass Mfg. Company, of which he was president at the time of his death. This company ranks among the first in the brass business in the amount of its productions and extent of its manufacturing ability.

Mr. Coe was also president of the Torrington Savings Bank, a vestryman in Trinity Church, Torrington, a member for 20 years of the Union League Club, New York, and a trustee of the Berkeley Divinity School at Middletown.

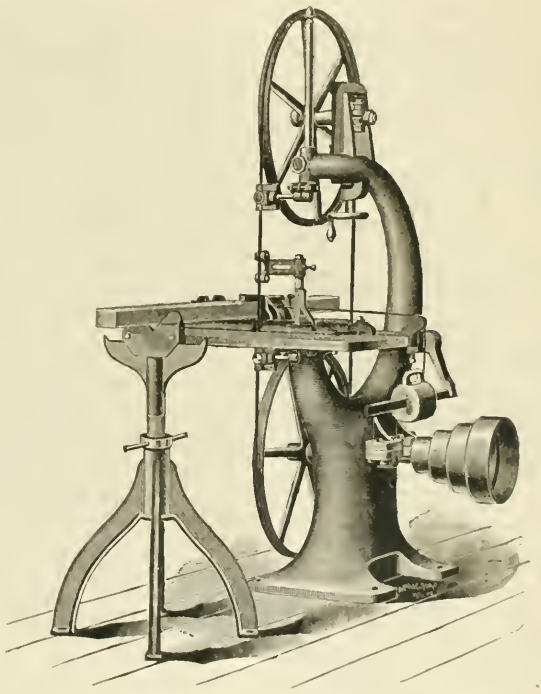
In 1845 Mr. Coe was elected to represent Torrington in the State House of Representatives, and to represent Waterbury in 1858. In 1862 he was elected to the Senate from the Fifth (Waterbury) District, and from 1876 to 1881 represented the Fifteenth District, the last two years being President of the Senate. In 1882 and 1884 he was nominated for Congress for the Fourth District, but was defeated.

A New England syndicate has purchased Texas timber lands valued at $750,000.

The Cross & Speirs Band Saw for Metals.

This machine was specially designed by the Cross & Speirs Machine Company of Waterbury, Conn., for sawing metals. The saws are made with a patent flexible back, or, in other words, the teeth are very hard and the rest of the blade is soft. This feature of soft back enables it to run over wheels without breaking.

The automatic feed attachment, as shown in the cut, can be removed instantly, leaving the table free for scroll work or hand feeding. With this attachment bars of steel and iron up to 5 inches in diameter can be cut. The material is led to the saw secured in the chuck or carriage by the weighted lever, as shown.



THE CROSS & SPEIRS BAND SAW FOR METALS.

This weight can be quickly adjusted to give the requisite pressure. The weight feed not being positive, it brings the metal against the saw only as fast as the saw can clear itself. When long, heavy bars are to be cut, the end is supported in a cradle which runs on rollers, and can be adjusted to the right hight by the hand nut on the iron support. This need not be used on short work. The carriage or chuck also runs on rolls and is brought to the saw by the weighted lever. The cone shaft is geared back 4 to 1, with cut gears which are concealed in the base. There are four changes of speeds which adapt it to steel, wrought iron, cast-iron, bronze, aluminum, or any metal that can be filed or cut by an ordinary hack saw. Each machine is provided with two Wright non-friction band saw guides, one below and one above the table. The carriage frame also has a special guide with side rolls attached, which carries and directs the saw slightly out of its natural course, when it is necessary to cut long pieces, enabling the long end of the bar to project beyond the part of the saw going up on the other side of the wheels. In short work it is not necessary to use the extra guide, as the regular guide is brought down close to the metal and holds the saw firmly up to its work.

The feed can be placed on either side of the saw as is best adapted to the floor space used.

The timber resources of Canada are being exhausted more rapidly than before since the export duty in logs was abolished. Mills on the Canadian shore of Georgian Bay and Lake Huron have been shut down and the material on which they used to operate is rafted across the lake to give employment to Michigan lumbermen and sawmills. Some Ontario villages have lost almost half of their inhabitants in consequence. Both logs and men are gone from the country. The budget speech just delivered in Parliament intimates that the Government intend to take means to preserve the forest resources.

The statement is made, without qualification, that three New York banking houses received $400,000 each from the Panama Canal Company for acting as members of the "American Committee;" $1,200,000 was divided among them in money, and one man got a salary of $24,000. Altogether there was disbursed in New York about $40,000,000 of the Panama Company's funds.

A company made up principally of gentlemen in Denver and Kansas City is pushing with vigor a railroad from the City of Mexico to Plazada Bay on the Pacific Coast, which will intersect "one of the richest mineral and agricultural regions of the country south of the Rio Grande." The immense coal fields at Coicoyan become the property of the railway company.

House Warming.—IV.

Having now ascertained the chemical composition of the combustible portion of the different fuels, together with the total heating power of each of the component elements and their aggregate, representing the calorific value of 1 pound of the fuel, we must consider, briefly, the fundamental principles of the elementary theory of heat; and also that of combustion from the chemical standpoint. This is absolutely necessary in order to demonstrate the application of the theoretical principles to practical operations; but we will endeavor to treat the subject in language sufficiently plain to render it easily understood by such readers as may possess but a limited knowledge of scientific matters.

MEASUREMENT OF HEAT.

The popular idea of the measurement of heat and cold is by the comparative temperature as indicated by the thermometer, an instrument with which all are familiar. Its principle of operation is the rising and falling of a thin column of mercury or colored alcohol in a glass tube having a bulb at its lower end filled with the liquid, the said movement being caused by the difference in the expansion of the glass tube and that of the mercury. The hight of the top of column with reference to the graduated scale indicates the temperature. Unfortunately, there is no universally standard thermometer. In this country and in England the scale of Fahrenheit is used; while in France, Germany, and, in fact, throughout the Continent of Europe, the Centigrade is the standard. Therefore, in most works treating of the subject of heat, the nationality of the writer will determine which of the two systems is used, though it is an almost invariable rule to designate it by the use of the abbreviations Fahr. or F. and Cent. or C.

As without a knowledge of the comparative relation of the two systems some of the most valuable literature on the subject becomes practically useless, the following simple formulæ are used for reducing from one scale to the other: Centigrade = (Fahrenheit − 32) ÷ 1.8. Fahrenheit = (Centigrade × 1.8) + 32. Thus (212° − 32°) ÷ 1.8 = 100° C. and (100° × 1.8) + 32 = 212° F. In the Centigrade scale the "freezing point"—or more properly, the temperature of melting ice—is the "zero," indicated by 0°; and the boiling point of water in an open vessel or at atmospheric pressure is 100° C. The Fahrenheit scale is based on the temperature given by a mixture of equal weights of pounded ice or snow and common salt. This is the zero, and the temperature of melting ice and that of boiling water are the other two important points in the scale. Of course, the zero and boiling temperatures are necessarily given arbitrary values—that is, any number of degrees might be given to designate boiling, and any desired effect of cold be called zero.

It is only necessary to divide the scale between the two points into equal spaces representing degrees, and measure all temperatures below and above zero and boiling to establish their comparative values. In case of the Fahrenheit scale, the space between 0° and 212° being divided into 212 equal graduations called "degrees," the temperature of melting ice—commonly called the "freezing point"—is found to be 32° and is therefore the resultant of the temperatures arbitrarily fixed for the freezing mixture and for boiling water. The Centigrade scale, however, having the 32° of Fahrenheit as its zero, would give a temperature of (0° + 32°) ÷ 1.8 = 17.78° minus (or say minus 18°) as the equivalent of Fahrenheit zero. All temperatures below zero are called "minus" quantities, and are distinguished by the subtraction sign placed before them, thus − 17.78° C. = 0° F. In the foregoing rules given for reducing the given temperature from one scale to the other it should have been mentioned that the formulæ as stated apply only to temperature above zero. For those below, the operation is merely reversed and would read: Centigrade = (Fahrenheit + 32) ÷ 1 8, and Fahrenheit = (Centigrade × 1.8) − 32. Thus: (0° + 32°) ÷ 1.8 = 17.78° C., and (17.78° × 1.8) − 32° = 0° F.

TEMPERATURE AND QUANTITY OF HEAT.

Temperature, however, is only the measure of the condition and not of the amount of heat contained in a body. For instance, if we apply the same degree of heat to a cubic inch of cast iron weighing 0.26 pound, and a cubic foot weighing 450 pounds, they will obviously have the same temperature. But in all calculations of this nature the important factor is the quantity of heat, and the temperature be comes merely an element in the calculation by which it is ascertained. It is clear that while a cubic inch and a cubic foot of cast iron at 100° will have the same temperature, yet the quantity contained by the cubic foot will be 1728 times as great as that in the cubic inch. And if we expend, say, 1 pound of coal in raising the temperature of the inch to the given point, it must necessarily require 1728 pounds to impart the same degree to the foot.

It is clear, therefore, that some standard of measure for quantity is required, and we have this in the thermal unit, or unit of heat. It is based upon the quantity of heat necessary to elevate the temperature of 1 pound of pure water from 32° to 33° F.* As this quantity varies slightly at different temperatures on account of the variable "specific heat," it is necessary to limit the measurement to the temperatures given; and it is readily seen that we have an absolutely exact standard of measurement, by means of which we may calculate quantities with the same accuracy as is possible in determining the degree of heat or temperature by means of the thermometer. But there are other factors entering into the problem quite as essential as the standard of measurement. It does not follow, nor is it true, that the same quantity of heat required to raise the temperature of 1 pound of water 1° will be required for, say, 1 pound of cast iron.

SPECIFIC HEAT.

This difference is termed the "specific heat" of bodies (solid, liquid and gaseous), and is the relative capacity for heat as compared with that of water as the standard. Thus, the specific heat of water being 1, and that of cast iron 0.13, the quantity of heat which would raise 1 pound of water 1° would increase that of the same weight of cast iron $\frac{1}{0.13} = 7.7°$ or, what is the same thing, 7.7 pounds increased 1°. While the specific heat is not uniform, but increases slightly with the temperature, it is not of sufficient importance in the present connection that it need be taken into account; and this is also true of many other details, from which we may eliminate considerations which, though absolutely necessary in exact calculations, will not materially affect the results of our practical application of the principles. As we progress in the investigation of our subject it will be necessary for us to consider the specific heat of numerous substances, and in the following table are given only such as will enter directly into the calculations. The figures given are the result of experiments, and are accepted as standard in all calculations of this nature.

* These are the temperatures generally used, though to be exact, it should be from 39° to 40°, as the latter is the temperature of maximum density of water.

Table IX.—Specific Heat of Various Substances, or the quantity of Heat Necessary to Raise the Temperature of 1 Pound 1° F. Also the Name of Authority by Whom Experiments Were Made. (Selected from Box "On Heat.")

Substance.	Specific heat.	Authority.
Water	1.00000	....
Fine wood	0.65000	Mayer.
Oak wood	0.57000	Mayer.
Coal	0.27770	Crawford.
Marble	0.21585	Regnault.
Coke	0.20085	Regnault.
Glass	0.19768	Regnault.
Burnt clay	0.18500	Gadolin.
Ice	0.50400	Person.
Cast iron	0.12983	Regnault.
Wrought iron	0.11379	Regnault.
Zinc	0.09555	Regnault.
Copper	0.09515	Regnault.
Brass	0.09391	Regnault.
Lead	0.03140	Regnault.
Tin	0.05695	Regnault.
Air	0.23790	Regnault.
Oxygen gas	0.21820	Regnault.
Hydrogen gas	3.40460	Regnault.
Nitrogen gas	0.24400	Regnault.
Carbonic acid gas	0.21640	Regnault.
Carbonic oxide gas	0.24790	Regnault.
Water vapor	0.47500	Regnault.

To illustrate the application of the above, and also for continual reference in our calculations, it is necessary to know the relative weights and volumes of air, at different temperatures, at atmospheric pressure. The next table gives the results of calculations by Box from a formula which need not here be given. The correctness of the result is sufficiently demonstrated by comparison with the figures obtained by Dulong and Petit from actual experiment in a range of temperatures from 32° below zero to 680° above.

Table X.—Weights and Volumes of Air.

Temperature. Degrees.	Volume.	Weight of 1 cubic foot, in pounds.	Temperature. Degrees.	Volume.	Weight of 1 cubic foot, in pounds.
0	0.935	0.0864	325	1.597	0.0506
12	0.960	0.0842	350	1.648	0.0490
22	0.980	0.0824	375	1.689	0.0477
32	1.000	0.0807	400	1.750	0.0461
42	1.020	0.0791	450	1.852	0.0436
52	1.041	0.0776	500	1.954	0.0413
62	1.061	0.0761	550	2.056	0.0384
72	1.082	0.0747	600	2.158	0.0376
82	1.102	0.0733	650	2.260	0.0357
92	1.122	0.0720	700	2.362	0.0338
102	1.143	0.0707	750	2.464	0.0328
112	1.163	0.0694	800	2.566	0.0315
122	1.184	0.0682	850	2.668	0.0303
132	1.204	0.0671	900	2.770	0.0292
142	1.224	0.0660	950	2.872	0.0281
152	1.245	0.0649	1,000	2.974	0.0268
162	1.265	0.0638	1,100	3.177	0.0254
172	1.285	0.0628	1,200	3.381	0.0239
182	1.306	0.0618	1,300	3.585	0.0225
192	1.326	0.0609	1,400	3.789	0.0213
202	1.347	0.0600	1,500	3.993	0.0202
212	1.367	0.0591	1,600	4.197	0.0192
230	1.404	0.0575	1,700	4.401	0.0183
250	1.444	0.0559	1,800	4.605	0.0175
275	1.495	0.0540	1,900	4.809	0.0168
300	1.546	0.0522	2,000	5.012	0.0161
1	2	3	1	2	3

From this table we see that a volume of air which at 32° would equal 1 cubic foot becomes at 2000°, 5.012 cubic feet; and that the weights of 1 cubic foot, at these temperatures, are 0.0807 pound and 0.0161 pound respectively. These variations of weight and volume are of the utmost importance in calculations for combustion, heating and ventilating.

Referring to the previous table, we find the specific heat of air to be 0.2379. The weight of a cubic foot of water at 32° is about 62.4 pounds, while that of air at the same temperature we find by the table to be 0.0807. Then $\frac{62\ 4}{0.0807}$ = say 774 cubic feet of air will weigh the same as 1 cubic

foot of water; and this volume divided by its specific heat $\frac{774}{0.2379}$ = say 3250 cubic feet of air will be raised 1° of temperature by the quantity of heat necessary to increase 1 cubic foot of water the same amount. Thus, while the relative capacity for heat of water and air by weight is as $\frac{1}{0.2379}$ = 4.2 to 1, we find that by volume it is as 3250 to 1—or, in other words, 62 4 heat units will alike increase by 1° the temperature of 1 cubic foot of water or 3250 cubic feet of air. And, as by the table we find also that the volume of air at 32° is 1, and at 2000° is 5.012, then 3250 × 5 012 = 16,339 cubic feet of air at 2000° will require the addition of 62.4 heat units to increase its temperature 1°, or to 2001°. In this calculation no account is taken of the variation of the specific heat due to increase of temperature; but, as before stated, it is unimportant in effect, and the above figures are practically correct.

Regnault has demonstrated that gases have, substantially, the same relative weight and volume at a given temperature as above given for air, and it is therefore only necessary to have their several weights at any given temperature, to enable us to calculate the weight and volume at any other temperature, by the use of the quantities given in the table. Thus, if oxygen at 62° has a volume of 0.9 as compared with air as 1, at same temperature, and weight per cubit foot of 0.08417 pound, we find that at 32° it will have a volume of 1.061 (as per table for air at 62°) × 0.9 = 0.9549; and the weight per cubit foot will be 0.08417 ÷ 0.9 and × 0 9549 = 0.08816 pound. As we know the volume of 1 pound to be approximately 0.9 that of 1 pound of air, and the weight at 62° to be 0.08417 pound per cubit foot, we have only to multiply the volume of air for the desired temperature (as given in the table) by 0.9 to obtain the relative volume of oxygen; and multiply the 0.08147 by this volume and divide by 0.9 to ascertain the weight per cubit foot. These figures are not exact, but are used merely by way of illustration. As we shall need to consider the several gases entering into, and resultant from, combustion and respiration, our next table will be in reference thereto—the quantities being based on a uniform temperature of 62°.

Table XI.—Weights and Volumes of Gases.

Gases.	Density—Air at same temperature = 1.	Volume at 62°.	Weight per Cubic foot, in pounds.	Cubic feet in 1 pound.
Atmospheric air.	1.00000	1.0610	0.07610	13.14
Oxygen	1.10563	0.9598	0.08414	11.88
Nitrogen	0.97137	1.0923	0 07393	13.54
Hydrogen	0.06926	15.3191	0.00527	189.70
Carbonic acid	1.52901	0.6939	0.11636	8.63
Carbonic oxide	0.96740	1.0967	0.07394	13.60
	1	2	3	4

Having now the necessary quantities, we may ascertain the volume, weight per cubic foot and cubic feet per pound for any temperature by the following very simple rules: For finding the relative volume, divide the number in column 2 of previous table, opposite the desired temperature in column 1, by the relative density of the gas in column 1 of last table. Thus, to find the volume of oxygen at 62°, we see that of air to be 1.061, and $\frac{1.061}{1.10563}$ = 0.9598, as per table. To ascertain the weight per cubic foot (for temperature above 62°) divide the weight as given in column 3, in Table XI, for 62°, by the new volume thus found, and multiply by the old, as given in column 2. For example, we desire to know the weight of 1 cubic foot of hydrogen at 82°, then $\frac{1.102}{0\ 06926}$ (as per col. 2, Table X) = 15.91 = volume at 82°; and $\frac{0.00527}{15\ 91} \times 15.3191$ = 0 005074 pound. If the required temperature is less than 62° the operation is reversed—that is, we multiply by the new volume and divide by the old. It is, therefore, but a question in simple proportion. It may be stated thus:

For temperatures above 62°:

15.91 : 15 3191 :: 0.00527 : 0.005074.

For temperatures below 62°:

15.3191 : 15.91 :: 0.005074 : 0.00527.

Asbestos.

In a very able paper read before the British Institute of Marine Engineers, J. Alfred Fisher, General Manager of the United Asbestos Company of London, gave some interesting information in regard to the manufacture and uses of asbestos, as illustrated in the works of the company with which he is connected.

As is commonly known, this valuable mineral is procured mainly from the mines of Italy and Canada. The product of these countries is stated to be the only kind of asbestos which answers the primary requirements of resistance to fire and fiber of suitable length for the purposes of manufacture. The Italian variety only is said by experts to be the mineral asbestos proper—belonging to the hornblende group of minerals; while that produced in Canada is in reality not asbestos proper, but a serpentine rock called chrysotite. Both descriptions, however, are of commercial value, as possessing the necessary qualities above mentioned. The asbestos obtained from the large veins, provided it contains no serious impurities, is classed as grade No. 1 and is used for spinning and weaving. The shorter stuff and such as contains impurities is classed as No. 2 and No. 3, respectively. These latter grades are used considerably in this country for various purposes.

PROCESS OF MANUFACTURE.

The works of the United Asbestos Company—who are an amalgamation of various companies which were started in Great Britain and Italy between 1871 and 1880—are located at Harefield, near London. There asbestos goods, in all the forms in which they are offered to-day, are manufactured.

Describing the process of manufacture, Mr. Fisher says: "Our works are divided into several departments. First, there is the sorting and opening department, where the crude asbestos is dealt with. The blocks of fiber or 'rock' are crushed and opened up in special machines in such a way as not to destroy the fiber, and are passed thence to 'shaking' machines, where the long fiber is separated from the short, and particles of rock removed. The long fiber suitable for spinning into thread is then taken into the carding and condensing department, and the short to the millboard and boiler covering departments. The treatment of the long fiber in the carding and condensing department is very similar to that in a textile factory, but its appearance would be scarcely encouraging to one who had been accustomed to wool or cotton. These latter staples, examined under the microscope, exhibit a notched or serrated appearance, which explains the ready way the material clings together when twisted. The peculiar nature of asbestos presents difficulties which are rendered more evident when its behavior in the machines is watched, but these difficulties are overcome by special appliances attached to the condensing machines. As the fiber comes from the condensers in the form of sliver or condensed thread without any twist, it lightly folds itself in cans placed there to receive it, and is then taken to the spinning and doubling department, where it is twisted into threads of every degree of fineness required. The thread then passes to the weaving and braiding department, where it is made into various forms of yarn packings, also into tapes and cloth. The cloth is then taken to the india rubber department, where it is proofed and made into what is known as asbestos and india-rubber woven sheeting, tape and rings for steam and other joints, and also into rolled cloth and square block packings for glands."

JOINTING AND PACKING MATERIALS.

Recognizing in these days of fast steaming and high pressures the supreme importance of jointing and packing materials on which reliance can be placed, the company produced six or seven years ago a combination of asbestos and metallic wire which, with further improvements, recently effected, fully answers their expectations. Attempts had been previously made in this direction, but the results were not considered satisfactory, inasmuch as the asbestos-metallic cloth referred to was simply woven either with a wire warp and asbestos weft, or with alternate threads of asbestos and wire. They inclose, by an improved method recently adopted, a fine brass wire in the center of every thread of asbestos in both warp and weft, thereby adding very largely to the strength of the cloth, while the wires are completely protected by the asbestos. This material is known as the Victor metallic cloth, and, being made into tapes and all sizes and shapes of joints as well as into round and square packings, is now largely used with satisfactory results by marine engineers and others.

Asbestos millboard is also produced at the works by a process very similar to that of ordinary cardboard; the fiber being beaten into a pulp with binding ingredients and then pressed into sheets and dried.

FIRE PROOF PAINT.

Another product of the works which is said to be most effective is asbestos paint, in which a considerable quantity of asbestos powder is used. In regard to this substance Mr. Fisher says: "Numerous public experiments have been carried out from time to time, proving the remarkable fire resisting qualities of this paint, the first being conducted under the patronage of the Lord Mayor and a distinguished company at the Crystal Palace in January, 1882. I had the honor, two or three years later, of carrying out experiments at South Kensington in the presence of H. R. H. the Prince of Wales, the Executive President of the Colonial and Indian Exhibition, which were pronounced satisfactory, and nearly 150 tons of the material were used on the buildings of that and the Fisheries, Health and Inventions Exhibitions held in 1883-4-5 6.

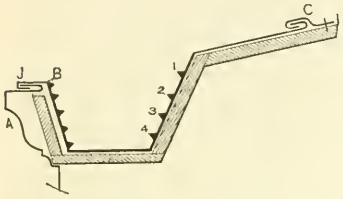
"At each of these exhibitions several small fires broke out at exhibition stalls, which might have proved very serious but for the protection afforded by the paint. I well remember one in which the fire occurred at a stall in a remote part of the buildings at 4 o'clock in the morning. The stall and contents were destroyed and the wooden floor of the building burnt through; but the wooden partition against which the stall stood, as well as the roof, both of which were painted, were scarcely injured. The paint was badly blistered, but the painted wood had not taken fire, as it doubtless would have done under ordinary conditions and probably with disastrous results."

Several other uses to which asbestos is put were briefly touched upon in the paper.

ROOFING AND CORNICE.

Material for Gutter.

From W. N., *New York.*—Replying to your correspondent, "W. D. M.," in *The Metal Worker* of January 7, who desired to know what material it was best to use for gutter lining, I submit the following: As the expense is not to be considered, it is best to use 18-ounce copper, by which is meant that a square foot or a piece 12 x 12 inches weighs 18 ounces. To show the allowance made for contraction or expansion the five illustrations have been prepared. Let A, of Fig. 1, represent a metal molding in which the gutter is planked of wood and lined with copper, as shown at B. Before bending the copper to the shape required the edges should be tinned on both sides, wherever a soldered seam is required. Care should be taken where the molding is of galvanized iron and the gutter lining of copper that the copper comes in contact with the galvanized iron, as shown at the lock J, Fig. 1. The copper should be well tinned on both sides to prevent the action of the copper upon the zinc coating when wet. It is a fact not well known to tinners that if we take a glass jar and fill it with water and place in it separately two clean strips, one of zinc and the other of copper and connect the two with thin copper wire, an electrical action is the result, and if it remained connected for a long time (as the action is very faint) the zinc would be destroyed, because, it may be said, the zinc furnishes the fuel for the electrical action, the same as wood furnishes the fuel for the fire. Therefore, if the lock J, of the copper gutter lining were not tinned outside and inside before being locked into the lock of the galvanized molding and it became wet with rain, the zinc coating would in time be destroyed by the electrical action of the two metals, and the iron would rust through. This applies to all copper work coming in contact with zinc or galvanized iron on outside work where rain would affect it.



Material for Gutter.—Fig. 1.—Wooden Gutter with Metal Molding.

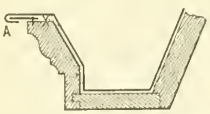


Fig. 2.—Lining for Wooden Gutter.

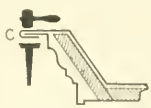

Fig. 3.—Metal Molding with Outward Flange.

The gutter lining shown in Fig. 1 should be locked as shown at J, and well soaked with solder, using heavy roofing coppers. The lock C should be fastened with cleats as shown, and the cross seams of gutter either be locked as in Fig. 4, or laid sharp as shown in Fig. 5, and a piece of tinned copper soldered over the seam, as shown at A. By having the copper tinned on the inside and outside at the edges of the sheet, and using a heavy soldering copper, the solder flows through the entire seam and makes a strong job.

The rugged heavy lines in the gutter in Fig. 1 show how the upright seams should be soldered. Forge the soldering coppers wedge shape, and in soldering the upright seams, soak them well with solder, using rosin or well-boiled acid. After the seam is soldered, place small ridges of solder at 1, 2, 3, 4, &c., on the inside of gutter as in Fig. 1; this makes a very strong seam. If the roof were of tin, it should be locked over the cleat C, shown in Fig. 1. By using this method there is not one nail driven into the entire gutter lining, it being only soldered at the lock J, if the molding were of metal, and at the lock C if the roof were of tin, and the cross seams soldered as described. If the entire gutter were of wood, as shown in Fig. 2, a strip of copper should be nailed to the top of the wooden molding, as shown at X, and the gutter lining locked into same, as shown at A. In Fig. 3 is shown a metal molding where the flange is bent outward, and the gutter lining locked over it, as shown at C. If the roofs were of slate in Figs. 2 and 3, the gutter lining would be fastened to roof by means of a cleat, as shown at C, in Fig. 1, and the entire gutter would be loose for contraction or expansion, with the exception of the soldered cross seams, which could be made as illustrated in Figs. 4 or 5. In Fig. 3 is shown how the seam is flattened by the use of a square head and mallet.

Fig. 4.—Lock for Cross Seam.

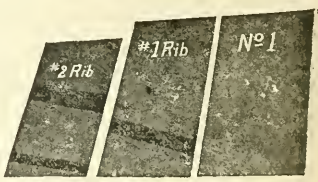
Fig. 5.—Laid with Seam Strip.

An item in these columns last week erroneously reported that an order for a 10-foot corrugating machine had been received from the Cambridge Roofing Company, Cambridge, Ohio, by Geo. C. Keene & Co. of Cincinnati, Ohio. The manufacturers desire to correct this statement. The order mentioned was received from the American Roofing Company of St. Louis, Mo.

Roofing Slate.

In the September issue of the "Transactions" of the American Society of Civil Engineers is a paper by Manafield Merriman discussing the strength and weathering qualities of roofing slates. After describing at some length the slate formation in Pennsylvania, the paper takes up the manufacture of roofing slates, some portions of which are likely to interest our readers. We therefore make the following extracts with accompanying illustration relative to the production of roof coverings of the character named:

"In the manufacture of roofing slates everything is done by hand except dressing the edges. The blocks delivered at the shanties are first split into thicknesses of about 2 inches. These are piled up in a shanty beside a workman called a splitter, who, with a wooden mallet and a long, thin chisel, divides each into halves, and continues the process until they are reduced to the required thickness of about $\frac{3}{16}$ inch. He then cuts out pieces in approximate sizes, and these are taken by an assistant and squared off into regular shape and size on a dressing machine.



Illustrations of Different Qualities of Roofing Slates.

The rock of some quarries requires to be kept damp from the time it is first exposed until it is split into the final sizes, otherwise the cleavage becomes difficult.

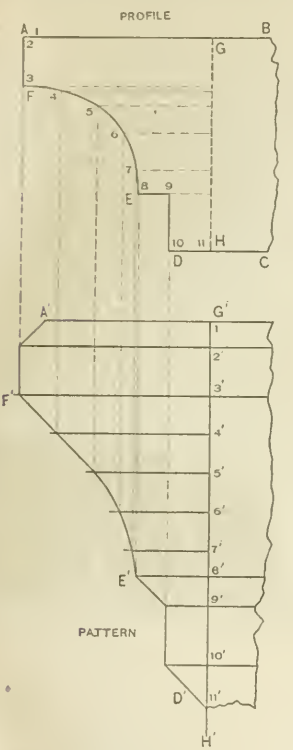
"Roofing slates are made in numerous sizes, from 14 x 24 inches down to 6 x 12 inches, the longer dimension being that which is placed parallel with the rafters of the roof. In all roofing which is properly done, a triple lap of 3 inches is allowed; thus, for a 24 inch slate 10½ inches are exposed, 10½ inches are covered by the slate above it, and 3 inches are covered by two slates above it. The amount of slate required to cover a space 10 x 10 feet in this manner is called a square, which is the unit by which they are sold. For slates 12 x 24 inches it takes 114 to make a square; for those 8 x 16 inches, 277 make a square, and so on.

"The normal product of roofing slates is called No. 1 stock, and this is entirely free from ribbons. Some quarries make second and third quality slates, called No. 1 Rib and No. 2 Rib, respectively, the former containing ribbons near one end only, so that when laid on the roof the exposed parts are free from them. These grades are illustrated in the accompanying cut. The color of the slate is a permanent dark bluish gray. The color of the ribbons, however, is nearly black at first, yet, on exposure to the weather, they exhibit a whitish efflorescence and soon show signs of crumbling and decomposition

This is due to the sulphide of iron which they contain, and also to their porosity and softness. Although the price of these inferior qualities is from 20 to 40 per cent. less than that of the standard stock, they should not be allowed on a roof which is to be regarded as a good piece of work."

Spacing Profiles.

From E. P., *Cleveland, Ohio.*—In the accompanying sketch let A B C D represent a section of cornice or molding, for which a rig t angled miter pattern is required. The usual method for obtaining the pattern will first be described. Divide



Spacing Profiles.—Diagram Submitted by "E. P."

the profile A D into any convenient number of parts, as shown by the small figures. At right angles to D C, draw G' H', upon which lay off the stretchout of the profile A D, through the points in which draw the usual measuring lines, drawing them parallel with the lines of the molding. With the T-square placed parallel with the stretchout line G' H', and brought successively against points in the profile A D, drop lines cutting measuring lines of similar number drawn from the stretchout line G' H'. A line traced through the points of intersection, as shown by A' F' E' D', will be the pattern required.

If it is not convenient to describe the pattern under the profile, as shown, proceed as follows: At right angles to the lines of molding draw G H, and divide the profile, as previously described Through the points in profile draw lines parallel with A B, cutting G H At any convenient place draw the line G' H', upon which lay out a stretchout of the profile A D. Through the points thus obtained draw the usual measuring lines, making them perpendicular to the stretchout line G' H'. With the dividers transfer the length of lines drawn from G H to profile, to lines of similar number drawn from G' H'. Through the points thus obtained, trace the pattern line A' F' E D', as shown. An inspection of the diagram will show that by taking the length of lines drawn from G H to A D, and transferring to the lines of similar number drawn from G' H', the same result is obtained as by dropping lines from the points in A D by means of the T-square.

When spacing curves, as E F, it is the custom with many pattern cutters to divide the curve into a certain number of equal parts. This requires some time, as a number of trials may be necessary before the exact division is secured. I seldom take the trouble to divide a curve into equal parts, but set my dividers according to the distance the measuring lines are to be apart, and space off the curve, as from F to 7 of profile. These spaces are also set off on the stretchout line, as shown from 3' to 7'. It is then easy to add the unequal space E 7 of profile, as shown by 7' 8' on stretchout line G' H'. I would like an expression of opinion from those readers of *The Metal Worker* who are interested in pattern cutting, regarding the most convenient manner of dividing curved lines. Should they be divided into a certain number of equal parts, or unequal, as shown in the diagram?

A Legal Question for Roofers.

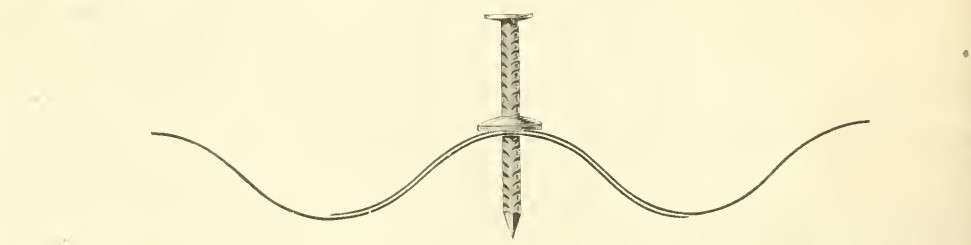
From J. H., *Washington, D. C.*—About a year ago I secured the work in my line from the builder (the general contractor) on a small residence to be built in this city. The specifications required the tin for the roof to be as follows: "A B's American-made roofing tin." When the building was nearly ready for the tin roof I wrote to Messrs. A B for samples and prices of their American roofing tin. Their answer was that they could not furnish any American tin for four weeks, but that they had plenty of other good tin, &c., Then I wrote to Messrs. C D for samples and prices of their American tin. After examining C D's samples I selected the cheapest as amply good enough (for I really thought it was well worth its price) Then I sent the sample from C D and A B's letter, and a letter of explantion of my own, to the builder, asking him what I should do in the matter. In my letter I said that the inclosed sample was American made, and, in my opinion, as good or better than the tin specified. A few days after this the builder told me to put the tin on like the sample I had sent him, but the architect stopped my men when the work was about half done. The contractor engaged another tinner to take off my tin and put on some of A B's American tin that the tinner had in stock at the time. Now the contractor wants to deduct the amount of the other tinner's bill from my contract. A clause in the specification gives the architect power to reject material that is not of the best, &c. Have I done my full duty or not, and should I pay the bill?

Answer.—The facts stated and the questions involved are so complicated that it is not surprising that doubt should arise in the minds of the parties as to their precise rights under the circumstances. We take the case to be that there was a complete and definite contract between the owner and the general contractor or builder. This contract was doubtless in writing, as such contracts usually are; certainly the specifications were written, and they constitute the principal and most important feature of the contract. The terms of this agreement are, of course, binding on the parties to it—the owner and the contractor. But they are not necessarily binding on a person not a party to it; a sub-contractor like "J. H.," for instance. In fact, just the reverse is the case. There is no duty or obligation, or contract liability, on the part of a sub-contractor to the owner; to no one, in fact, except the person with whom he made his contract, namely, the builder. This being so, it follows that "J. H." is not bound by the specifications in the main contract, but only by the terms and conditions of the agreement he makes with the builder; that is, by the sub-contract. Of course, the builder may have included, and probably did incorporate, the terms of the main contract in his contract with "J. H.," so far as the tin work was concerned. But it must be kept in mind that the only contract on which "J. H." is liable is that with the builder. It does not appear whether this agreement was in writing or not. It is immaterial which, except that if written, the exact language used might be of importance in determining the question. By this contract, "J. H." agreed to furnish "A B's American-made tin." Of course he is bound to carry out this promise literally and exactly. He cannot furnish any other tin, whether it is better or not. Furthermore, it makes no difference whether "J. H." can get the tin or not, or whether A B has any or not. The fact that it is or may be impossible to carry out the contract does not relieve the promisor—"J. H." in this case. As the law phrases it, "Impossibility of performance is no excuse." We suppose that under "J. H.'s" contract with the builder he was obliged to furnish the tin required at once when demanded. He could not be allowed to wait a month. If the builder had desired he could have compelled "J. H." to furnish the material, and if "J. H." could not do so, then the builder could have done the work himself or contracted with some one to do it and have charged all the damage from loss of time or increased cost to "J. H." But, at the same time, the builder had the right if he was willing to take the risk to vary the contract with "J. H.," to waive the exact performance as to the particular kind of tin, and to allow the use of another kind. And "J. H." had the right to rely on this change of terms and to go on with the work as he did. "J. H." was not, as we have shown before, bound by the builder's contract with the owner, even if he knew of it. The builder, however, still remained bound by it, and he took the risk of the material he consented to have used being rejected by the architect, and he must suffer the loss. This is all on the assumption, however, that the builder did not make an arrangement that if the tin was rejected "J. H." should sustain the loss, or, in other words, that "J. H." should take the risk. If nothing was said as to who should take the risk, then it falls on the builder. There is perhaps a further reason why the builder should bear the cost, and that is, that, acting as an ordinarily prudent man, he should have gone with the samples to the architect and ascertained, before the roofing work was

commenced, whether this material would be satisfactory and accepted. This was plainly his duty and not that of "J. H." Very likely he was anxious to have the work completed without delay, and feared that the architect would not accept the material on inspection of the sample. By consenting to the change of material he made a new contract with "J. H.," which abrogated the former contract to that extent; and when "J. H.," on the strength of this arrangement, proceeded to do the work in good faith, he simply did his duty and was not responsible for the subsequent action of the architect, and the consequences. More than that, it was a contract which the builder could have enforced against "J. H." if he had seen fit. If "J. H." had not gone on and done the work, the builder would have had a claim for damages against him. It was not a matter of convenience or concession to "J. H." when the builder directed him to put on the C D tin, although incidentally that was true, but it was a matter of strict contract duty and obligation. It follows naturally that not merely is "J. H." not liable for the cost of taking up the C D tin, but that he has a claim against the builder for the amount of the contract, less, of course, the value of the C D tin, which "J. H." still has on hand, and less the actual cost of doing the work. In other words, he has the right to the profits he would have made if the material had been accepted and the work completed.

Lead Washers.

As shown in the accompanying illustration, the lead washers, manufactured by Littleford Brothers, Cincinnati, Ohio, are



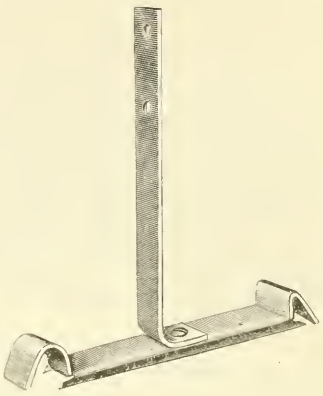
Lead Washers for Roofing.

used for putting on roofing and siding. These washers, it is claimed, make an absolutely water-tight joint on any surface, whether convex, concave or flat. They also, it is said, prevent rust below the nail head and the head from cutting into the sheet, and in this way they insure a more durable job. The washers are put up in boxes of 100 pounds, each containing 325 washers, which is sufficient for treating from two to three squares. The washer is made in two sizes, No. 8 with a hole in it $\frac{5}{32}$ inch in diameter, and No. 12 with a hole $\frac{3}{32}$ inch in diameter.

T. N. Bray has purchased the interest of his partner, J. M. Bolton, in the firm of T. N. Bray & Co., roofing and stove repairs, at Sioux City, Iowa, and the business will hereafter be conducted by a corporation under the name of T. N. Bray Company. They are also agents for H. W. John's asbestos roofing.

The Boss Eave-Trough Hanger.

In the accompanying illustration we present a new eave-trough hanger—the Boss—which is being placed on the market by Henry B. Todd, Meriden, Conn. This device, which is a new form of the Yankee hanger, and made under the same patent, is offered to meet the demand of the trade for a strong and convenient article, at a low price. It is non-adjustable, and made of soft steel, formed in dies under a press. The advantages claimed for the Boss hanger are that it will fit all sizes of beads, and that it has points that penetrate the trough just below the bead, making the attachment to this side of the trough as strong and substantial as the opposite one. The points on both ends of the hanger penetrate the trough from the inside; consequently, the weight of the gutter has a tendency to force it further on to the points; the more weight the stronger being the connection. The hanger is made with straps of assorted lengths, packed in one-gross boxes. Tongs to apply the hangers are also provided.



Boss Eave-Trough Hanger.

Operating a Cornice Brake.

From J. H. C., *Shelburne, Ont.*—If you could inform me where I could get general directions in print for operating an 8-foot cornice brake I would be much obliged to you.

Answer.—We are not aware of any directions published treating on this subject fully. Some manufacturers of cornice brakes give a few general directions in their catalogues as to the different shapes which may be formed upon the brakes they make, but further than this they seem to leave it to the ingenuity of the operator to manage for himself.

Laying Tin Roofs.

From E. P. B., *Osterville, Mass.*—I was very much interested in the letters lately published in *The Metal Worker* about buckling of tin roofs. Now, I think if more care was taken in making the roofs solid before placing the tin, the roofing would last much longer. In laying tin roofs I have often come across places where it was hard work to drive a nail owing to the boarding being springy.

Rhodes, Dickelman & Co., Forest, Ohio, issue an illustrated catalogue and price-list of steel roofing, galvanized eave trough, &c., of their manufacture. In an introductory note to the trade they mention that since the last catalogue was issued they have reorganized their business, enlarged its working capital, added several new departments, and made sundry improvements in old ones. In the early pages of the catalogue they direct attention to their double folding lock seam, Stuble's cap seam, standing pressed seam and roll and cap roofings, which are made of genuine steel and no iron enters into them. They also refer to the way the paint is applied as rendering it not liable to crack or peel off, and direct attention to the careful inspection which the sheets undergo. They state that the sheets will stand double seaming, lengthwise or crosswise, without breaking. The painting is done by machinery, the sheets being dipped into the paint and passed through a pair of rolls and from the rolls to a set of brushes. The paints used are mixed with boiled linseed oil with no driers. The first 35 pages of the catalogue contain a variety of illustrations respecting steel roofs, together with particulars of the material. The next division of the catalogue is devoted to the eave trough department, which embraces a full line of eave troughs, conductor pipes, pipe hangers, cut offs, &c. The manufacturers call particular attention to the fact that their eave troughs having no beads, are equally applicable to right or left side of building, and are in consequence very quickly hung. Toward the end of the catalogue attention is given to conductor pipes of various kinds, elbows, conductor hooks, ridging, &c., and the whole is concluded with testimonial letters and an alphabetical index.

The development of Northern Mexico will receive a new impulse on the completion next July of an extension of the Mexican International line from Monclova to Sierra Mojada, one of the most thriving cities in that region and an important mining and agricultural center, within 35 miles of illimitable salt beds.

"The Metal Worker" Competition in Skylight Pattern Cutting.

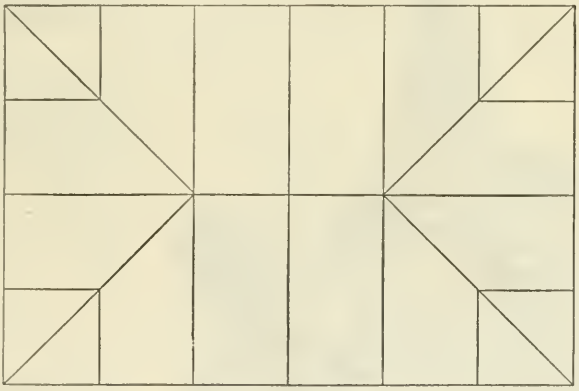
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

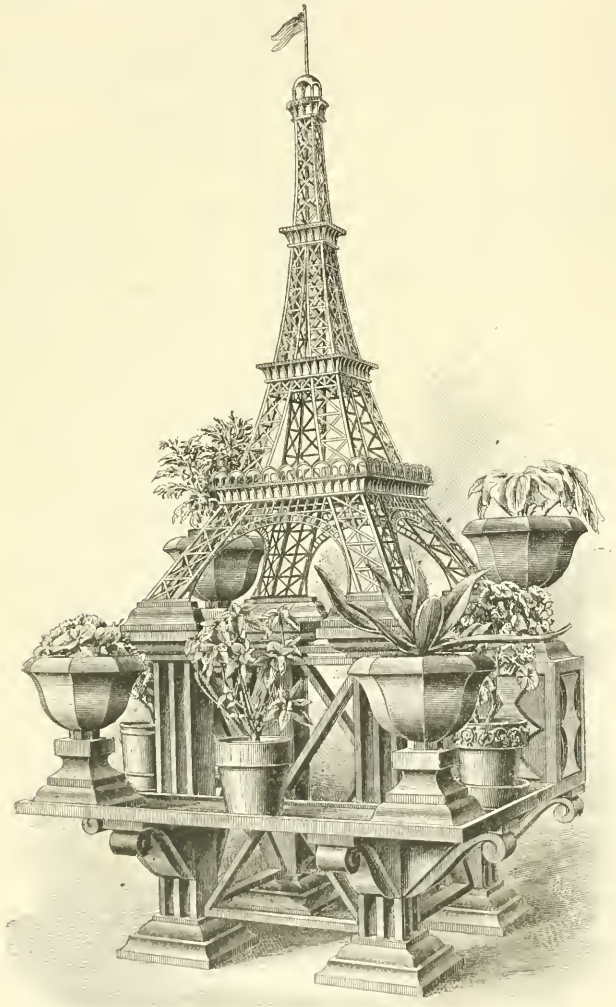
The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

THE TIN SHOP.

The Eiffel Tower in Sheet Metal.

We present herewith an illustration of a very elaborate piece of sheet-metal work, made by John Engel of Helena, Montana, who favored us with a photograph of the article, together with a description, which we condense as follows from his letter: The reproduction of the Eiffel Tower is made for a flower stand, bird cage and fish stand combined. The fish glass, which should be in front of the front arch of the tower in the picture, is taken off, so as to give a better view of the tower. The bird cage occupies the part from the first to the second gallery, the bars fitting inside of the tower on each side, and fastened by catches; but they also are removed to give a better effect. The lower part, or flower stand, is made entirely of No. 27 galvanized sheet iron, and consists, as will be seen, of four posts, on which there is a base and top mold, the four posts being held together by galvanized iron bars, ¾ x 2½ inches. On each front post are two brackets, and on the back posts one, on which a shelf rests, the shelf being 9 inches wide and made in the form of a shallow trough, so that the water draining out of the flower pots will not fall to the floor. In addition to the four vases there is space for seven more flower pots, three being shown in the photograph. The vases at the back, it will be noticed, rest on pedestals. These octagon vases are also made of galvanized iron, and have a square base. At the center of each vase is a ½-inch hole for the water to drain off.

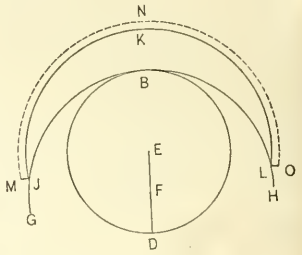
The tower itself is made of tin, and all the bars, beams and cross-pieces are folded on both sides, so that there are no sharp edges. The cross-pieces do not lap over one another, but are put together flush and soldered. There are nearly 1000 pieces in the entire structure. The lower part is tinted like gray sandstone, while the tower is gold bronze and the gallery is silver bronze. The entire hight from the stand to the tower is 7 feet.



The Eiffel Tower in Sheet Metal.

Pattern for Measure Lip.

From T. M., *Boston.*—A convenient method of describing the pattern for a measure lip, which can be used for measures of any size, is shown in the accompanying diagram. Let A B C D represent the top of measure for which a lip is required. From the center E draw E D, and bisect E D at F. With F B as radius, and F as center, strike the arc G B H. With the same radius, and with E as center, strike the arc J K L. An allowance for edge or wire can be made, as indicated by the dotted line M N O.

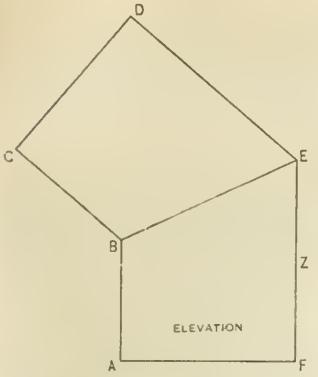


Pattern for Measure Lip.

Pattern for Beveling Elbow.

From C. M. S., *Bridgewater, Mass.*—Among the numerous methods shown in *The Metal Worker* for obtaining the pattern of a beveling elbow, I have seen none so easy to follow or comprehend as the following. While the method may not be geometrically correct, it is near enough so for practical purposes. In Fig. 1, let A B C D E F be the elevation of elbow for which a pattern is required. Draw the line G K in Fig. 2, in length equal to the circumference of elbow. Bisect G K at L, and erect the perpendicular L M, which gives the center line of pattern. Also erect the perpendiculars G H and K J. From G and K of pattern set off the distance A B of elevation, as shown by G P, K O of pattern. Also from L of pattern set off the distance F E of elevation, as shown by L N of pattern. Draw P N and N O. Divide N O into eight equal parts, and set off distances equal to three of these divisions from points, O N P, as shown at T S Q and R. Set the dividers

so as to strike the arc S N Q, as shown, and with the same radius strike the arcs



Pattern for Beveling Elbow.—Fig. 1.—Elevation of Elbow.

P T and R O. Then draw the lines *d c* and *a b*, touching the arcs P T, S N Q and R O, as shown. The lines *a b* and *c d* can be drawn free hand if desired.

The Lalance & Grosjean Mfg. Company's New Mill.

Wednesday, the 22d inst., was fitly celebrated in all parts of the country. Among the events which marked the anniversary of Washington's birth, not the least noteworthy was the formal opening of the new rolling mill which the Lalance & Grosjean Mfg. Company of Woodhaven, L. I., have erected at Harrisburg, Pa. The rolling mill, which is among the most complete establishments of its kind, is destined for the production of light sheet iron to be used in the manufacture of the enameled ware and domestic utensils for which the concern have long been famous. It will yield an output of from 250 to 300 tons of 24 to 26 wire gauge sheets weekly, the bulk of which will be consumed by the Long Island factory. The sheets will also be cut into the desired patterns at the Harrisburg mill, ready for stamping and finishing at the company's main establishment, thus greatly expediting the manufacture and augmenting the capacity of the concern, while relieving the factory of the handling of scrap, which has hitherto been a great drawback there.

The new mill is situated in a lot of 12½ acres, which the company secured in West Harrisburg. It possesses great advantages of location, being on the line of the Pennsylvania Railroad, and in close vicinity to the coal and iron regions of Pennsylvania.

BUILDING AND CONTENTS.

The building, which was erected by the Pennsylvania Steel Company, is 220 x 208 feet, supported by iron columns, and a "lean-to" 40 feet wide. It is completely fire proof, in that iron and glass have been exclusively used in the construction. The equipment consists of two sheet mills, each having five pairs of rolls, independently worked; 12 heating and two annealing furnaces, a bar mill run by its own engine, five refining furnaces, a 6000 pound steam hammer, and an ample provision of shears and other tools of the latest and most efficient type. A special feature of the establishment is that these shears and other portions of the equipment are provided with separate engines for operating them, instead of being connected with the main engines, thus obviating the necessity for a multiplicity of shafting, belting, &c. The power is supplied from a battery of ten horizontal tubular boilers, 6 x 8 feet, and a 30 inch stroke blowing engine with 18-inch steam cylinder and 48 inch air cylinder supplies air to the refineries. In all respects no care or expense has been spared to make the mill a model of its class, special attention having been paid to efficiency and economy of manufacture, and the adoption of all facilities in the way of machinery and construction to attain that end, as well as to secure good lighting and ventilation in the building.

ADDITIONS TO FOLLOW.

The works were commenced early last summer under the supervision of J. J. Thomas, who remains as superintendent, while J P. Luce, assistant manager, will have charge of the clerical and business part of the new establishment. The firm's engineer, J. B Barrody, has had charge of the erection of the mill, and we understand that he is now engaged upon plans for extensions, which will be shortly carried out. The additions contemplated are a second building for making tin plates, for home use by the company, and a third structure in which will be manufactured "black iron goods," as distinct from the coated ware made at Woodhaven.

OPENING EXERCISES.

The officers of the Lalance & Grosjean Company are: Florian Grosjean, president; Augustus J. Cordier, vice president; and E. W. Martin, secretary and treasurer.

As previously stated the mill was started on the afternoon of Wednesday, February 22. Special cars attached to the Pennsylvania express conveyed President Grosjean and the members of the company's staff and their families, together with several guests, from New York to Harrisburg, where on arrival they were met by a number of prominent citizens of that place, who accompanied the party to the mill. The opening ceremony was simple and brief, consisting in the starting of the machinery by the little son and daughter of Vice-President Cordier. On their pressing a lever which released attached weights the busy wheels and engines were instantaneously set into play all over the building. After thorough inspection of the plant a banquet was spread in the mill, to which the firm and their guests, all the employees of the mill and a number of visitors from Harrisburg and its vicinity were invited. A brief address of hearty welcome to the city was made by M. W McAlarney, editor of the Harrisburg *Telegraph*, and responded to by George L. Nichols, Jr., one of the directors of the company, on behalf of the venerable president, Mr. Grosjean. Among the visitors who accompanied the New York party were F. G. Niedringhaus and E B. Brown of the St. Louis Stamping Company; A. M. Brush of Holbrook, Merrill & Stetson, San Francisco, Cal; H. A. Manning of Manning, Bowman & Co., Meriden, Conn.; Charles X Cordier of Waterbury Brass Company; H V. B. Nash of T. B. Coddington & Co., New York. In addition to President Grosjean, Vice-President Cordier and Messrs. J. H. Smith and Geo. L. Nichols, Jr., directors of the company, occupied the position of hosts.

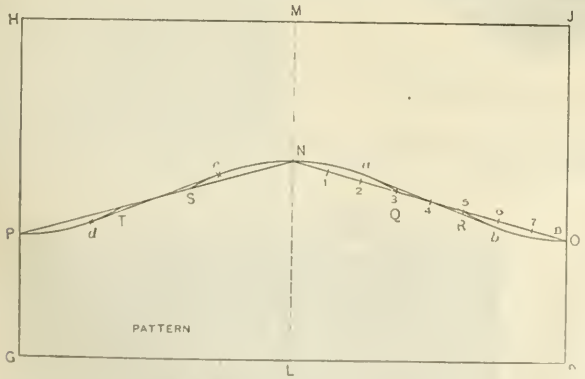


Fig. 2.—Method of Obtaining Pattern.

Manual Training Schools.

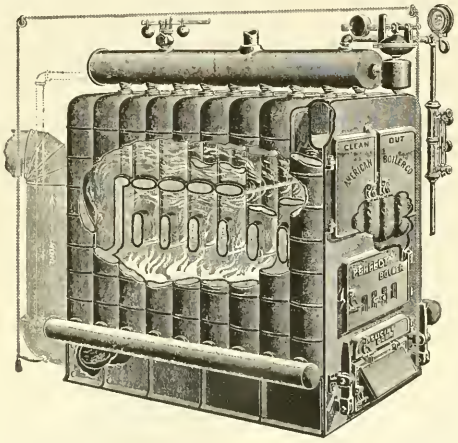
An eloquent plea for the American apprentice was made by President Ittner of the National Association of Builders, in his annual address delivered before that body in St Louis, 14th inst. Mr. Ittner advocated the founding of manual training schools and night trade schools for the benefit of apprentices. He spoke of J. Pierpont Morgan's gift of $500,000 to Colonel R. T. Auchmuty of New York, the pioneer of trade schools, and said that he wrote Mr. Morgan a letter of thanks in the name of the National Association of Builders and the American boy, to whose advancement Colonel Auchmuty is devoting the remainder of his days. Mr. Ittner said favorable reports were received of the trade school established by the National Association at Philadelphia, although no progress had been made in the trade school project for St. Louis. He hoped the day would come when no American boy would be deprived of the privilege to become a skilled workman; that there was no reason for the present discrepancy in wages between skilled and unskilled labor, and that the dearth of skilled labor to-day is due to the proscription of the apprentice system by labor organizations. As a man who had the benefit of an apprenticeship in two trades, Mr. Ittner expressed his sympathy for the youth who was debarred from a trade by arbitrary regulation. He looked to the trade school to remedy this state of affairs.

The report of the formation of a flour trust by Western millers is discredited in Buffalo. There are 28,000 mills in the United States, according to last statistics, about one-half of which are spring wheat mills. This trust scheme has been attempted in years past, but without success, and spring wheat millers could not expect any better success, now, as competition is much keener in the spring wheat product than the winter wheat.

STEAM AND HOT-WATER.

Perfect Heating Boiler.

W. M. Mackay, manager of the School and Public Building Heating and Ventilating Department of the American Boiler Company, was recently granted a patent on a cast iron sectional water-tube boiler, which is to be manufactured by the American Boiler Company. This apparatus, to be known as the Perfect, is an improvement on a boiler of somewhat similar design formerly made by the Richardson & Boynton Company, one of the three concerns which sold out to the American Boiler Company. Fig. 1 is a broken view of the boiler, while Fig. 2 shows the separate sections of which it is composed. The improvement in this apparatus is said to be longer fire travel and internal circulation, besides other new features. All the surfaces, it will be noticed, are tubular in form, which is referred to as giving greater strength than the flat surface, and permit it to carry higher pressure. The internal circulation is specially emphasized, which insures a uniform and steady water line. The sections are connected together by means of return manifolds and steam drums and long screw connections. The boiler has a cast-iron base and a rocking grate, the steam outlet being taken from a separate chamber in the base, at the back of the ashpit. Reference is made to an ingeniously arranged damper elbow which operates automatically, checking the draft and admitting cold air. When soft coal is used as fuel a plate is provided for covering the air inlet, the operation of the damper, however, being the same as where hard coal is burned. The new apparatus is said to be particularly easy to clean, for by the opening of a single clean-out door on the front of the heater, all the surfaces can be easily reached with an ordinary 3 inch wire cleaning brush. The boiler, which is to be made in a number of different sizes in lengths and widths of grates, is intended to be used in portable form. The manufacturers recommend, however, that it be covered with non-conducting material to increase its power and reduce the consumption of fuel by preventing the radiation of heat.



Perfect Steam Boiler.—Fig. 1.—Broken View of Boiler.

HEATING NOTES.

THE *Electrical World* says: "The first practical use of electricity to heat hot-water coils, the inventor claims, was made recently, when R. A. McCormack of Ottawa, Ontario, installed the Ahearn electric heaters in his store. The switch was turned on at 8.30. The temperature was then 50°. In 20 minutes the cold was out of the pipes, and at 9 o'clock the temperature had risen to 68°. The water for the coils is contained in five heaters in the cellar, the total capacity being about 23 gallons. As in the regulation heaters, the water is heated by coils of wire of poor conductivity that pass between the inner and outer sheets of the heater. The hot water is then forced up by the laws of hydrostatics to the coils above. By having five separate heaters the heat and expense can thus be regulated. On a mild day one or two sections may be used. About 300 feet of pipe are used in the store proper, and the heaters keep the cellar warm. Mr. McCormack says the beauty of the system is that it takes up only one-quarter of the space of a furnace and boiler, requires no bother with coal or ashes, and the cost of putting in is less than half that of a furnace.

THE RAYMOND & CAMPBELL MFG. COMPANY, Middletown, Pa., issue very pretty circulars relating to the Lindemuth Sun steam heaters of their manufacture. An outside and sectional view of the heater are shown, which clearly illustrate the construction and special features of the apparatus. A general description is presented in the circular, as well as the chief merits alluded to.

THE AMERICAN RADIATOR COMPANY, 111 and 113 Lake street, Chicago, have prepared a large sheet illustrating their various types of radiators. It is mounted with rollers for hanging. Some 37 different styles of radiators are shown, covering all possible requirements in steam and hot-water radiation, both direct and direct-indirect, as well as a number of constructions for indirect radiation alone. This sample sheet is very handsomely executed. It will be found a great convenience by architects, builders and fitters.

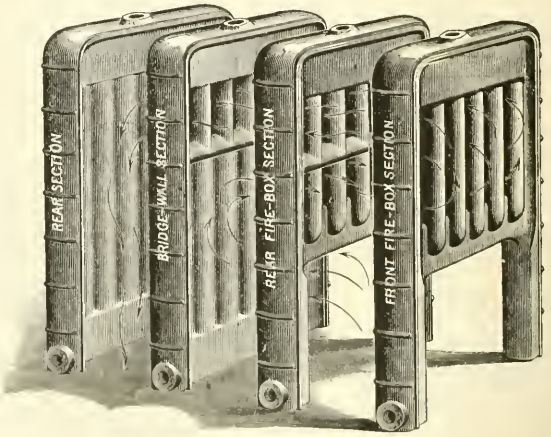


Fig. 2.—General View of Separate Sections.

English Practice In Hot-Water Heating.—XXI.*

BUILDING WORKS.—GENERAL INFORMATION.—QUANTITIES.

In treating of the heating of the buildings the various phenomena relating to circulation, radiation, &c., are governed by precisely the same natural laws as in glass house works. The circumstances and general conditions and the general points to be considered are, however, so different that it becomes almost a distinct calling from horticultural works, and in many cases a man who can execute one may be almost at a loss with the other. The difference is as great as with those works for the supply of hot water for baths and domestic purposes, this being a quite distinct branch of practice.

One peculiarity of building works is the pressure that manifests itself when the pipes extend up two or more floors of a building; a pressure that needs consideration in many ways, particularly as to the joints of pipes, &c., which must be capable of withstanding it.

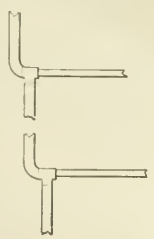
The pressure comes about in this way. When pipes extend any distance above a boiler, and they are charged with water, the weight of this water must be pressing downward toward the boiler, and we learn from any work upon hydrostatics that the pressure so exerted is 1 pound per square inch for every 2 feet 4 inches hight. In other words, if a pipe of 1 square inch area and 2 feet 4 inches high be filled with water, its contents will weigh 1 pound. If the pipe was set up on its end the weight of its contents, 1 pound, would be pressing upon what it was supported by. It is very necessary to avoid the notion that the pressure is in any way associated with the heat; it is merely weight of water. An apparatus extending, say, 42 feet in hight would cause a pressure of 18 pounds to be exerted upon every square inch surface in the boiler, or in the pipes near the boiler. As we rise above the boiler the pressure decreases in like ratio, that is, every 2 feet 4 inches above the boiler the pressure becomes 1 pound less, until we arrive at the top, where the pressure is *nil*. It is only vertical hight that counts; it matters not how the pipes may be carried, the distance from the supply cistern at top to the boiler at bottom, in a vertical line, is the sum of the pressure exerted. It may be noted that the pressure is identically the same whatever the size of the pipe, whether they be, say, 1 inch or 4 inch; but the reader is referred to my elementary work on hydrostatics for these details.

It should be mentioned, as there is an idea rather prevalent that the size or area of the feed cistern in some way governs the pressure, that this impression is wrong. The contents of this reservoir make no difference in pressure except as to its hight. If in one case a very shallow cistern was used, and in another instance a very high cistern, and this latter filled quite full, then the higher cistern would bring a greater pressure to bear, but only 1 pound for every 2 feet 4 inches of its hight, the same as in a pipe. If we wanted to get the exact pressure we should measure from the level of the water in the cistern to the center of the boiler; the shape or extent of the cistern need not be considered. It may be well at the same time to explode the idea that pressure assists the circulation. It does not do so, yet at the same time as a high pressure means a high apparatus, a good circulation is always (or nearly so) obtained when a good pressure exists. It is, however, the hight of the apparatus that increases the motive power; the pressure is merely a consequence, and has no active part in aiding circulation. If the pressure was down one pipe and up the other it would be a different thing, but the pressure is equal down all pipes, irrespective of whether the water has to travel up or down them.

The strain upon the boiler and pipes need not have any injurious effect. It makes care necessary in jointing the pipes, as just mentioned, and when the apparatus extends a good hight, the shape of the boiler has to be considered. Many a saddle boiler has been bulged inside by this cause, as it must be remembered that, say, 40 pounds pressure per square inch amounts to between 2 and 3 tons per square foot. Of course, the larger the boiler the greater likelihood of its becoming misshapen by the strain. If the vertical hight of the apparatus is mentioned to the boiler maker he will say if the boiler selected is suitable.

If an apparatus burst through this great strain or pressure of water, no harm would ensue unless any one be near enough to be scalded by the outrush of hot water (supposing it to be hot). The fracture would be merely a fissure and no expansive or rending force would be felt. If the apparatus had its expansion pipe and other outlets closed an explosion would occur, which would have very different results.

In works of this kind there is, we may say, never any lack of motive power or strength of circulation. The extent to which the pipes always run vertically gives us this. It is so different to horticultural work, in which vertical pipe is absent. When the mains are quite vertical, which is often the case, the circulation is so rapid sometimes as to carry the water right past the branches, ignore them, so to speak, and provision has frequently to be made to obviate this. Sometimes the provision is in the form of stop valves; but a natural and simple arrangement, if found necessary, is to joint the pipe at every branch, as Fig. 87.



English Practice in Hot-Water Heating.—Fig. 87.—Showing Joints in Pipe at Every Branch.

The size of the mains differs more in these works than with horticultural apparatus. They vary from 1¼ inches to 3 inches or even 4 inches. The former size is only suited for moderate sized works, but with vertical pipes it is quite astonishing what a quantity of hot water small pipes can deal with. When these mains are not used for radiating purposes they should be covered carefully, as already described. There should be no loss of heat. Where cost will admit, it is best to err toward having mains of sufficiently full size; it is a real gain, provided they are covered and cause no loss of heat. It will have been gathered that the higher the apparatus extends, the smaller the mains may be, to give certain results; but never run the risk of their being too small.

The water supply to these works is provided by a cistern of the necessary capacity, as per the rule already given. Sometimes the water is added by hand, but in these works it is usually a ball valve that automatically makes good the loss. The particular objection to these articles is that, at the best, they are not very reliable, and in fulfilling this duty, the demand for water being so small, they get stuck and out of order for want of regular use. They should be looked to regularly. It is a not uncommon practice to terminate the upper extremities of the main flow and return in a small tank; it is a very good plan, and in several little ways is found a convenience. If the apparatus is hand filled, the water is put into this tank, which will answer as a filling cistern. In

Fig. 88.—Ordinary Form of Air Cock.

many cases the highest part of the circulating pipes may be a coil, and no tank is permissible. The tank is only suggested when conditions are quite favorable.

The discharge of air from the apparatus is quite different to anything we have yet spoken of. It is practically impossible to use air pipes; they would sometimes have to be 60 feet long, as it would be imperative that they reach up to a point above the level of the supply cistern, and as we should require one from every branch of pipes and every coil or radiator, the expense would be great, and they would be visible in all directions. The customary arrangement is to use air cocks, one at each highest point: if pipes, one at each furthest extremity; if coils or radiators, then one upon the extreme top of each of these. The ordinary form of air cock is as Fig. 88, but a new one having several good features has been introduced, as Fig. 89 (section). Air cocks need regular attention about once a fortnight, as air is continually finding its way into the apparatus, and collects at the highest points. When opening air cocks to discharge air it is necessary to hold a cloth over, as we cannot tell whether the air is out until water issues, and the issue of water under pressure, however little, may do damage to wall papers or decorations, &c.

When an apparatus is wholly devoid of air pipes it is very desirable to have an expansion pipe at some point. It is not absolutely necessary, as the cold supply pipe and cistern allow for the actual increase in bulk of water, but if the apparatus overheats and other such possible happenings, the expansion pipe becomes useful. It is never a great expense.

Fig. 89.—Sectional View of Improved Air Cock.

QUANTITIES.

A cubical contents table is about the only practical means of arriving at the quantity of pipe needed in works of this character. There is a rule, which is based upon the area of glass (windows), the loss of heat by walls (certain thicknesses, materials and position), and the degree of ventilation, &c. This rule, however, is rarely if ever resorted to. If it were

*Reprinted from the London *Builder*.

discussed here it would involve so many points, particularly as to aspects and ventilation, as to complete the rest of these papers by itself.

Hood, when he gave his excellent, though complex, rule to the world, applied it almost wholly to glass-house work, which it is well adapted for, but he also, unfortunately, endeavored to make it apply to building works by allowing so many cubic feet of air per person occupying the room or place. It will be seen what a weakness this introduces, in the fact that, firstly and chiefly, the number of people has no relation to the size of the apartment. A small lecture room may be calculated to have an average of 200 people in it, yet some private reception rooms would be nearly as large and yet not exceed an average of 20 occupants. A rule founded this way will not work at all satisfactorily unless a variety of allowances be made, with doubtful results. It would be better to calculate the wall and window surface, but this is not so good as basing calculations on cubic contents.

In arriving at quantities in these works there is always some guesswork introduced and allowances needed—in fact, the tables given by all writers are subject to this. In the use of the following table it must be seen that, 1, the glass or windows are of ordinary area or number; 2, that the ventilation is normal (except in drying rooms, &c., where unusual ventilation is allowed for). The place to be heated must not be naturally damp or exposed by being an addition to a main building, or standing out so that it is liable to greater cooling influences than ordinary. Again, consideration must be given as to whether the boiler fire has skilled or indifferent attention. In buildings, particularly residences, the attendant is very commonly a page boy or man servant, who only knows that the fire must not be allowed to go out. All these things occur readily to the mind after a little experience. It is hard to say what allowance is necessary in these different cases, but supposing all of them to exist at once, it would necessitate doubling the quanity of pipe given in the following table:

Temperature required.	Quantity of 4-inch pipe through which to circulate per 1000 cubic feet capacity in a brick-built room. Windows as usual.	Some of the uses for which the heat may be required.
Deg. F.	Feet.	
50	6	Coach houses, &c.
55	7	Work rooms, &c
60	8 to 9	Churches, bedrooms.
65	10	Living rooms.
70	35	Drying rooms, herbs, paper, &c. Free ventilation. This heat when empty and dry.
75	45	
80	60	
100	110	Drying rooms for moist articles, laundry work, &c. Full ventilation. This heat when empty and dry.
110	140	
120	180	

This table is based upon the water in the pipes being at a temperature of 180° F., and the lowest external temperature 20° F. Ordinary conditions: A foot length of 4-inch pipe is as nearly as possible a superficial foot of surface; for 3-inch pipe add one third; for 2-inch pipe the quantity must be doubled.

For the higher temperatures given good attention at the boiler is necessary, and the water kept or as near boiling point as possible. The allowance necessary if pipes are in channels with gratings over (or coils beneath floors) is the same as with glass house work, viz, one-third more pipe needed. This commonly occurs in church work which has either lines of pipes in channels, or stacks of pipe here and there beneath the floor, with gratings over. The latter causes a very disagreeable amount of heat to be felt by those whose seats are near these openings.

Utilization of Wind Power.

An instructive article in *The Iron Age*, by G. D. Hiscox, M E, treats of "Possibilities in Utilizing the Power of the Wind," describing the purposes to which the time-honored windmill is adapted at the present day, and demonstrating the advantages of gathering the free power of the wind for our every-day uses. The direct application of wind power, except for the propulsion of vessels, says Mr. Hiscox, apparently began, in a crude form, about the seventh century; and the windmill, with its four great arms, which wasted three-fourths of the wind power, continued to retain more or less of its original form down to a late date in Europe and the East. The American form, consisting of numerous blades, utilizing every available foot of space within the area of revolution, marked a great advance in the cost and efficiency of wind power. This type is now fast gaining ground in Europe, as, with the same breeze, the same power may be had from a modern mill of one-half the size of the clumsy inheritance of antiquity prevalent in the Old World.

Although the general use of windmills for power purposes declined during the present century, owing to the general use of the steam engine, still wind power holds its own for many purposes, and may be applied to still further uses. There is, for instance, no power so cheap for water supply at the present day, and within its range of power, as the windmill. For the supply of small towns, through a regular water-works system, the windmill takes the lead for economy over even a water wheel, and it may be located at the source of pure water. In a town of 1000 inhabitants, requiring a supply of, say, 50 gallons a head per day, the requirement can be met by the work of a windmill 25 feet in diameter, lifting the water into a reservoir 100 feet above the spring, or a 30-foot mill lifting 200 feet.

The question of a practicable means of storage and transmission of an intermittent power like the wind, in order to utilize that power at any time desired—that is, to transform it into a uniform power available for immediate application—is disposed of by Mr. Hiscox, who suggests three methods:

1. Storage of power by compressing air.
2. Storage of water by pumping into a reservoir.
3. Storage of electrical power by charging storage batteries.

Each of these offices can be performed by a windmill, and have been actually carried out in practice with complete success. In the case of air power the mill, when combined with a pump for water supply, becomes a valuable adjunct of thousands of farms and country seats, providing, in addition to irrigating and general water facilities, a small power for other uses, as for running lathes or small machinery, at a small expense compared with steam or electricity. The water storage of wind power is a most economical form for house, farm and irrigation purposes, when combined with large reservoirs. The storage of 300,000 gallons in a reservoir, 100 feet square by 4 feet in depth, can easily be attained by means of a 30 foot windmill under normal conditions. The mechanical work requiring power on a farm or plantation, for grinding, sawing, threshing, ginning and pressing cotton, or grinding sugar cane may also be undertaken.

In the storage of electricity for power and light from the operation of a windmill there is a wide field of usefulness. A 30-foot windmill will be equal to the supply of 32 16 candle power lamps, and supply the water required for a large country house. This has been tested for over three years on a large scale in Cleveland, Ohio, where, by means of a 56-foot windmill, power has been stored successfully and kept in constant readiness in a storage system of 408 cells, each with a capacity of 100 amperes, for all the power requirements of a large establishment fitted with 350 incandescent lamps.

The following are the estimated costs of plant for the various systems of power storage above detailed:

One 20-foot windmill, with all necessary adjuncts, for compressed air power plant, $1800.

One 30-foot windmill, with reservoir for water storage of wind power, $2175.

One 20-foot windmill, with dynamo, storage batteries, &c., for electric storage plant, $1715.

These, although apparently high prices for from 1 to 6 horse-power, are not really high when the utility and freedom from running expenses, attendance and danger are duly considered; and this is what particularly recommends wind power to every farmer, small manufacturer or country dweller.

A Mammoth Chimney.

From a Western paper we extract the following details respecting a chimney recently erected in Denver, Col., which is said to be the highest structure of its kind on this continent:

The tall chimney of the Omaha and Grant Smelter has just been put into use and is giving complete satisfaction. Some trouble was experienced in getting the smoke through it at first, owing to the large amount of frost which had collected on the inside. This stack, which is the tallest in the United States, consists of an outer shell and a core. The total hight of the chimney is 352 feet 7 inches, and it weighs, including the foundation, 12,876 500 pounds.

There were consumed in the construction of the chimney 1,943,000 brick, 8,480 bushels of lime, 1508 barrels of Portland cement; 131,143 pounds of iron of various shapes, including the cap, which weighs 22 000 pounds; 930 yards of concrete, and 233 cubic yards of sand. The outer shell is 48½ inches thick at the base, 13 inches thick at the top and has a pressure at the bottom of 148 pounds to the square inch. The thickness of the core is 26 inches at the base and 9 inches at the top, with a pressure of 160 pounds.

The whole structure stands upon a foundation 18 feet high, and has an exposure to the wind of 9230 square feet. Should the big chimney ever stand in the way of a tornado it would be capable of resisting a wind pressure of 369,200 pounds. The force of the wind in a tornado would amount to 255 pounds per square inch on the windward side and 5 pounds on the leeward side.

Before entering the chimney the smoke passes through an immense number of dust chambers in which the minerals which are held in suspension in the gases are condensed and collected. When the plant is completed there will be some 2 miles of these conduits, but at present there are but about three quarters of a mile in use. It is expected that the entire system will be finished and in use early in the year.

Immigration into the United States during January was 14,831, against an immigration in January, 1892, of 18,057.

THE LETTER BOX.

Moisture in Hot Air.

From J. H. C., *Galion, Ohio.*—I wish to ask through the columns of *The Metal Worker* if cold air taken from out of doors loses any of the moisture it contained in passing through a warm-air furnace? Has not the air as much moisture after it is heated as before? Is it necessary in taking air from the outside to have a water pan in the furnace? Does not the air taken from without the house contain all the moisture needed without a water pan?

Answer.—It is quite certain that the passage of the air through the heating drum of a hot-air furnace does not either increase or decrease the amount of moisture contained. Apparently, however, it would decrease it, and the explanation of this is the fact that air has a greater capacity for moisture at a high temperature. For instance, the air may be taken in from out of doors when it is nearly at the point of saturation—that is, holding all the water it can. On passing through the hot-air furnace and being highly heated, the total amount of moisture remains the same, but the air is then capable of taking up a great deal more water, so it will seem to be much drier because it will evaporate the water from all moist surfaces. What gives the feeling of dryness to the air is that the water from the skin is carried off, and that is the only means of testing the air, unless we use regular instruments to do so. Although, as we said before, the total amount of moisture is not altered by the passage of the air through the heater, it should be borne in mind that the relative amount or percentage per cubic foot is decreased. If a certain amount of air contains a certain amount of water, and that volume of air be increased to twice its volume in passing through a hot-air furnace, it stands to reason that the percentage of water in the heated air per cubic foot will be only half as great as in the cold air entering the furnace. When it comes to the matter of advising our correspondent on the use of a water pan, all that we can say is that opinions differ. Some of the furnacemen think that a water pan is useless, if not a positive disadvantage. They do not argue against the addition of moisture to the heated air, but they say that the water pan becomes a receptacle for all sorts of dirt, and is likely to give a bad odor to the air, if not introduce impurities in it. Of course, this argument does not hold where a water pan is carefully attended to, but then, as a matter of fact, are water pans carefully attended to in the majority of cases? This is a question that the ordinary furnaceman who objects to the water pan presents. Another objection urged is that the amount of water that the air will take up in passing through the furnace is insignificant, and really would not be noticeable. Our correspondent can figure this out himself, taking the capacity of an ordinary water pan, measuring the velocity of the air as it passes through the cold-air box, and the area of the cold-air box and the length of time it takes to dry up the water in the pan, he can calculate how much water is taken up by each cubic foot of air entering the house.

Suggestion to Hollow-Ware Makers.

From J. F. D., *Grayson, Col.*—I have often wondered why the stove, pot and kettle makers did not put better shaped

Suggestion to Hollow-Ware Makers.—Fig. 1 —Ears Cramping Cover.

ears on their pots and kettles. When you lift one by the bail the bail comes close against the side of the pot, cramps the cover and lifts it up before lifting the pot, as shown in Fig. 1. Why don't they put good lugs on so that the bail will pull away from the pot when you lift it and let the lid rest on top of the pot? Fig. 2

Fig. 2.—Ears to Free the Bail.

will show the idea that I mean in recommending the use of better shaped ears. Why don't the makers put on ears of this kind is what I want to know every time I have to trim the pot cover and be so very particular about the size.

Painting Conductor Pipe.

From S. H., *McConnelsville, Ohio.*—I would say, for the benefit of your correspondent "G. R. C.," Mansfield, Pa., that my way of painting conductors is to make them ready to go up, so as not to have any soldering to do, as the heat burns the paint off. I then take wooden plugs and plug up one end of the pipe, pour about half a gallon of paint into the conductor and then plug up the other end. After running the paint backward and forward so as to cover the whole of the inside, I stand the pipe up and let it drain. I find this an effectual, speedy and cleanly way.

Size of Cold-Air Duct for Furnace.

From E. P. S.—What should be the capacity of cold-air duct to supply furnace having three 11-inch and two 10-inch heating pipes?

Answer.—We are not aware that there is any fixed rule to be used in estimating the size of cold-air duct for a furnace, as much would depend upon location, length of duct, number of angles, &c. Some furnacemen make the cold-air duct eqnal in area to one-half the total area of the hot-air pipes, while others consider two-thirds or three-fourths to be the proper size. Considering the area of an 11-inch pipe to be 95 square inches and that of a 10-inch pipe to be 78 square inches, we would have $95 \times 3 = 285$, the area of the three 11-inch pipes, $78 \times 2 = 156$, the area of the two 10-inch pipes, and $285 + 156 = 441$, the total area of the three 11 and two 10 inch pipes. If the cold-air duct was to be made one-half the area of the hot-air pipes the capacity of duct should be one-half of 441, or $220\frac{1}{2}$ square inches. For this size the duct could be made $12 \times 18\frac{1}{4}$ inches, inside measure. If the duct was to be made two-thirds the area of hot-air pipes (441) its capacity should be 294 square inches. For this size the duct could be made $12 \times 24\frac{1}{2}$ inches, inside measure. If the duct was to be made three-fourths the area of hot-air pipes (441) its capacity should be $330\frac{3}{4}$ square inches. For this size the duct could be made $12 \times 27\frac{1}{2}$ or $14 \times 23\frac{1}{2}$ inches, inside measure. By using a duct of large size an abundance of fresh air could be secured when required, and by placing a damper or slide in the duct the air supply can be regulated as desired.

Keeping Track of Too's.

From R. E. C., *Mansfield, Pa.*—I would like to get, through the columns of *The Metal Worker*, the ideas of other tinners on keeping track of odd tools in the shop. My men have been in the habit of taking tools out and losing them and not reporting the same. And often they would return the tools to the shop and throw them down almost anywhere, so that when they were wanted it was difficult to find them. The tools I mean are of the odd kind, such as wrenches, hammers, ropes, pulleys and the like, kept in a first-class tinshop, and which have to be used in some work. I thought of several ways, but they all seemed to take up too much time. What I want to learn is some shorter way that will not take so much of the foreman's time to keep track of the tools of this kind that are taken ont of the shop by the other men.

Alloying Tin and Zinc.

From J. H. L., *Kansas City, Mo.*—Will you please inform me through the columns of *The Metal Worker* how to mix tin and zinc to make them unite?

Answer.—In a recent work on mixed metals, it is stated that tin and zinc can be alloyed by fusion producing more or less malleable combinations. The list of alloys given in the work show various compositions from the proportion of 1 part of tin to 99 parts of zinc at the one extreme to 99 parts of tin and 1 part of zinc at the other extreme. An investigation of the character of tin and zinc was made by Guettier, and he describes the characteristics of the variously proportioned alloys. It appears that when the tin is in small proportion there is a tendency for the metals to separate at the bottom of the mold. An alloy of 50 parts of tin and 50 parts of zinc, however, is recommended as giving good results, and it is stated that more zinc would produce an alloy not so well mixed, besides being more crystalline and brittle.

Tinning Soldering Coppers.

From C. L. F., *Clay City, Ill.*—I would suggest to "E. T.," Milwaukee, Wis., whose letter appeared in *The Metal Worker* of January 28, that he use a brick with rosin to tin his coppers, on account of it having more grit than a board and a better coat of tin will stick to it. Sal-ammoniac will do good work in tinning coppers, if very hot. To the apprentice, I would say, file clean all four sides, then file off sharp corners and round the point a little.

Cement for Glass and Metal.

From D. M. G., *London, Ont.*—In reply to "G. A.," Akron, Pa., whose inquiry appears in *The Metal Worker* of February 4, I send herewith a recipe for cementing glass and metal. Take ground white lead, mix with furniture varnish, then sift in some litharge. Mix well with the white lead and let it stand for about 20 minutes, when it will be of the consistency of mixed putty. The metal to receive the glass should be coated with a quick-drying brown baking japan or furniture varnish and allowed to get tacky before putting the cement and glass in place. Finally bake with a slow heat for about 10 hours.

Size of Registers for Round Pipes.

From J. G. S., *Portland, Ore.*—In reply to the question in *The Metal Worker* of January 28, respecting the relative sizes of registers necessary for 9, 10 and 11 inch round warm air pipes, I would inform your correspondent that 66⅔ per cent. of the opening in a register is figured as the open spaces and 33⅓ per cent. as the solid metal. Hence, for a 9-inch pipe to carry 63 square inches we use a register 9 x 12, which discharges 72 square inches. An 8 x 12 will do, as with it the discharge is 64 inches, but we prefer a little more than is necessary. A 10-inch pipe has a capacity of 78 inches, and for this we use a 10 x 12 register with 80 inches capacity. For 11-inch pipe and 95-inch area we use a 10 x 16 register with 107 square inches of capacity.

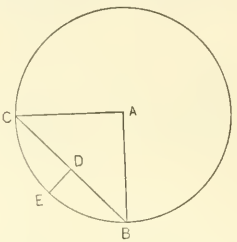
Piston Packing.

From A. McA., *Kearny, N. J.*—I have an air pump 4-inch bore and 4-inch stroke, double acting, the chamber is of cast iron. To prevent friction I use cast rings for packing. I want to compress from 10 to 15 pounds. Would you please advise me what would be the most practicable packing for the piston, best in operation, &c.

Answer.—Use oak-tanned cup leathers for packing the piston; these can be procured from any pump-supply house.

How to Find Circumference of a Circle.

From C. W. F., *Onawa, Iowa.*—Your correspondent in New Haven, Conn., "C. E. S.," in *The Metal Worker* of January 21, asks for a simple rule for finding the circumference of a circle of a given diameter. Here is one which, no doubt, most old tinners know, and which is exactly correct every time. I send a diagram, as it is the best way I can explain it, and it may be some help to the boys. Describe the circle of the given diameter, then mark off ¼ of the circle B C. This is easily done by laying the square on the circle with the corner of the square at the center and draw the lines A B and A C, then draw the line C B. Bisect the line B C and draw the line D E at right angles to it. Three times the diameter of the circle plus the line D E will be the exact circumference of the circle. I do not know that I can explain just why this is true, but you can



How to Find Circumference of a Circle.

try it, boys, and you will find that it is a simple and absolutely correct rule. I wish some one who is higher up in mathematics than myself would explain why this rule is correct.

Note.—We do not think there is any particular explanation of the correctness of this rule beyond pointing out the fact that the line D E should be a certain fraction of the circumference, for, according to our correspondent's letter, the line D E must be equal to 0.1416th part of the circumference. As C B is a quarter of the circumference, it is very evident it must be the same proportion of the total length in circles of all sizes. It must be borne in mind, however, in talking about rules being absolutely correct, &c., that these terms are only relative. What is absolutely exact in measuring lumber would not be considered exact in measuring silk, and a pair of scales that will weigh a ton of coal will not be used in determining the weight of a diamond. What we mean to say is, that for all practical purposes, a rule may be so closely correct that with ordinary instruments we cannot find any error, and yet if we had very delicate instruments and tested these rules, they might be found wrong by some very small amounts that, however, need be taken no account of by practical men.

Origin of "Carpenter" and "Plumber."

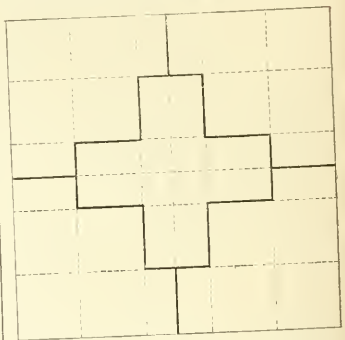
From F. D., *Union City, Tenn.*—Why is a carpenter called a "carpenter," and a plumber a "plumber?"

Answer.—Both words are of Latin origin; "carpenter" being derived from *carpentum*, a wagon or carriage, and *carpentarius*, a maker of the same. The word has in course of time widened its meaning, so as to include all artificers in wood. "Plumber" takes its rise from the Latin word *plumbum*, lead, and literally means a worker in lead. The French equivalent, *plombier*, explains itself in that language, *plomb* being the French for lead.

The Farm Problem.

From P. H., *New Madrid, Mo.*—When I spent 6 cents postage on the apple problem, I had no idea of being made the recipient of so valuable a benefit as that submitted by your Troy, N. Y., correspondent in *The Metal Worker* of January 28. As to the man with his thousand-acre farm, I think he can have his way easy enough and get located in the center of the plot and surrounded by his sons, provided he wishes no outlet for himself. By measuring off 200 acres in the center, no matter whether round or square, there will be left at the corners 200 acres for each of the other four lots. If this is not correct I leave the matter to the farmer and his sons, who ought to be more interested in the division than the writer. The sketches sent do not represent the shape of the farm I would like, but they are my solution of that problem as near as I can get at it.

From C. A. J., *Cobden, Ill.*—In the *Metal Worker* of January 28, the problem was stated by "S. J.," Troy, N. Y., respecting a thousand-acre farm intended to



Sketch Showing Solution of Farm Problem by "C. A. J." and "H. O."

be divided into five equal plots, one in the center. The accompanying sketch shows the way that I would divide the farm.

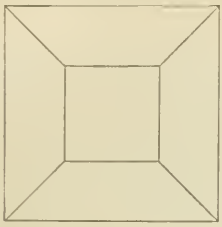
From H. O., *New Orleans.*—Let the old farmer divide his farm into 25 squares of 40 acres each, in the manner shown in accompanying sketch, and I think he will get matters about right.

Note.—Both the above correspondents have hit upon the same method, as shown in the accompanying illustration. A criticism to be made on this solution, as well as on several others received, is that it is merely graphical, the dimensions of the several farms not being figured out.

From T. S, *Philadelphia.*—I forward inclosed rough sketches, as my solution to the farm problem given by "S. J.," in your issue of January 28. If the old man should get on the outs with his children, how would he get out without trespassing?

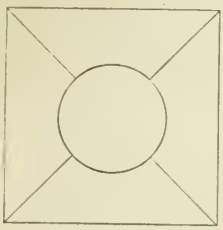
Note.—Our correspondent, "T. S.," gives us three methods of dividing the farm, proceeding on the fact that 200 acres comprise 8,712,000 square feet, the square

root of which is 2951 feet 8 inches. In the first example he places the father's farm, 2951 feet 8 inches square, in the center of the plot, drawing lines from the corners to the corners of the outer square, forming four equal divisions for the four sons in the same manner as illustrated in solu-



Solution No. 1 of Farm Problem by "P. H."

tion No. 1 by "P. H." In the second solution the dividing lines are drawn from the centers of the four sides of the inner square, forming four L-shaped spaces of equal size. In the third, the



Solution No. 2 of Farm Problem by "P. H."

lines are drawn from the corners of the inner to the edge of the outer square, forming four long rectangles of equal size.

From S. J. H., *Bristol, Vt.*—As a solution of the farm problem by "S. J." in *The Metal Worker* of January 28, I submit inclosed diagram with dimensions of farms.

Note.—The diagram gives a similar solution to the third figure presented by "T. S.," Philadelphia, namely, a rectangular space in the center of the plot, 178.9 rods square, with four rectangular spaces of 110.55 rods by 289.75 rods at the sides.

From A. P. E., *Ottawa, Kansas.*—I herewith submit the following solution to the 1000-acre problem by "S. J." in *The Metal Worker* of January 28:

Note.—This correspondent presents a figure containing a rectangular space in the center, 200 x 160 rods, equal to 32,000 rods, or 200 acres. From the center of the sides he draws straight lines to the outer edge, inclosing four L-shaped spaces containing in the larger limb 200 x 120 = 24,000 rods, and in the smaller limb 100 x 80 = 8000 rods, or 32,000 rods = 200 acres in each portion.

From J. H. C., *Groton, Conn.*—I have seen the problem given by "S. J." in *The Metal Worker*, or its equivalent, put in this way: A farm of 1000 acres to be equally divided between a father and four sons; the father to retain 200 acres with buildings in the center of the original farm, the four sons to have 200 acres each of land adjoining the homestead. These to be of uniform shape. All turns of division fences to be at right angles. Inclosed find diagram of the solution of above.

From J. C. F., *Grand Forks, N. Dak.*—I send you a solution of "A Country Problem" given in *The Metal Worker* of January 28. The father's farm is square in center of the 1000 acres. His four sons' farms will have the L shape on the corners of their father's farm, as in inclosed diagram.

Note.—The sketches supplied by "J. H. C." and "J. C. F." (without, however, noting the dimensions) are both similar to that described as the second solution of "T. S.," Philadelphia, namely, dividing the outer space into four by lines drawn from the centers of the four sides of the inner square, forming four L-shaped spaces for the sons—the limbs being of equal size.

From H. W., *Tacoma, Wash.*—I herewith submit a solution to the problem of "S. J.," Troy, N. Y., in *The Metal Worker* of January 28. One acre contains 160 square rods, 1000 acres contain 160,000 square rods; hence the original piece was 400 rods each way. Each to have an equal share must have 32,000 square rods.

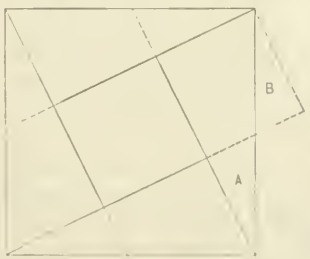
Note.—This correspondent proceeds in an ingenious manner by placing the father in the center in a farm measuring 240 x 133⅓ rods, with a son on each side in a farm of similar dimensions. This leaves a long narrow rectangular space on the top and bottom, 400 x 80 rods, for the third and fourth sons.

From W. E. W., *San Diego, Cal.*—Inclose solution of problem given by "S. J." of a 1000 acre farm to be divided equally between a farmer and his four sons. The farm being square and containing 1,000 acres to be divided among five persons, gives 200 acres to each. Dividing the farm into squares of 10 acres each, to give the four sons equal portions of like shape and size, let each son take a share as shown in inclosed diagram, leaving the old man's portion in the center of like size but different shape.

Note.—The diagram inclosed shows the center, or father's farm, as a square of 160 acres, with four spurs of 10 acres each at the corners; the four sons' portions being placed at the corners of the plot.

From S. J., *Troy, N. Y.*—I inclose herewith sketch showing method of solving the problem that I presented in a recent issue of *The Metal Worker*. You will notice that my plan is to find the middle of each side of the plot, then from each opposite corner draw lines to these points.

Note.—We reproduce herewith our correspondent's sketch. We regret that he



Solution of Farm Problem by "S. J."

has not gone into careful explanation of this, for while it would be generally accepted that the solution is correct, each one will have to study out the matter for himself. In fact, he presents quite a geometrical problem. We would say, however, for the benefit of those who do not wish to puzzle over the matter that the solution depends upon the two triangles A and B being equal to one another in area. Furthermore, each of these triangles is equal to one-twentieth of the entire 1000-acre lot, or one-fourth of each of the farms. As it is therefore equal to one-fourth of the square farm belonging to the father, and to one-fourth of the triangular farms allotted to the sons, the triangular farms must be the same area as the square one. It is not necessary to prove this, as it would require a good many lines and figures and explanation.

We have printed a number of the solutions received, as well as several diagrams, but we cannot undertake to publish any more answers, for if we did those of our readers who are not interested in agricultural matters might justly complain that their rights were being trespassed upon.

Combination Heaters.

From N. W., *Newark Valley, N. Y.*—I am in trouble. I have a pipe radiator 9 feet long with 6 lengths of ¾-inch pipes, and there is just room enough to put it under the bay window on the floor. I put a 1½-inch coil in the hot air furnace to heat the water and 10 feet from the furnace put a T with 1¼ and ¾ inch pipe and later expect to add more radiating surface, but have only put the ¾ pipe radiator in as yet and that one is the one that bothers me with the air or steam. After the air or steam is let out of the pet cock it works all right, until the fire gets down, and then when the fire is raised again it fails to work, as there is air or steam in the pipe. I want to put the other two radiators to take the heat off, so the pipe will return the water cold to the furnace, which, I think, will keep it from making steam, for I believe the trouble is due to steam. I think there is not enough radiator surface to take the heat as fast as the furnace will make it. Is the trouble steam or what is the cause of it? Do combination furnaces work evenly? Are they a success generally and would either steam, hot water or air alone work better?

Answer.—Our correspondent's trouble is caused by the formation of steam. This is due to the fact that the coil in the furnace and the surface in the radiators are not correctly proportioned one to the other. The even working of the apparatus may be effected by either reducing the coil in the furnace or by adding surface to the radiators. When combination furnaces are set and adjusted properly they work as evenly as other systems. Those who use well-designed combination systems of heating speak as highly of them as those who use simple systems of steam, hot water or hot air.

The Manhattan Railroad has lost an important suit. Judge Ingraham of the Supreme Court decided on February 13 that the company should pay into the City Treasury 5 per cent. of the net receipts from 1880 to 1890, and also from this time forward. The amount will aggregate about $2,000,000. Judge Ingraham's decision relieves the city from all responsibility for damages in suits instituted by property holders against the elevated road. The company will appeal from this decision.

THE RETAIL STORE.

The Hardware Dinner.

THE FIFTH ANNUAL DINNER of the Hardware, Metal and related trades of New York was given at Sherry's, Fifth avenue and Thirty-seventh street, on Tuesday evening. The gathering was notable and representative, and while naturally a majority of those present were from New York, New England and near-by States, the far West and intermediate territory was well represented. Irving M. Scott, president of the Union Iron Works at San Francisco, the progressive shipbuilding plant that has added such cruisers and battle ships as the "Charleston," "Monterey" and "Oregon" to the new navy, had expected to be present, but was unavoidably detained at the last moment. The New York Produce Exchange and Massachusetts Board of Trade contributed to the number seated at the guests' table, which was worthily presided over by President Williams of the Hardware Club. The trade centers of St. Louis, St. Paul, Cleveland, Pittsburgh, Buffalo and other cities sent their quota, while Congress, the clergy and press did honor to the occasion in the presence of notables who responded to various toasts. The method of arranging tables and seats was much the same as that followed a year ago, while the admirable plan of providing each guest with a programme showing his place at table avoided the confusion otherwise inseparable in such a large gathering. The committee decided to fill the large room comfortably and no more, and while the tables were the same in number the space allotted to individuals permitted more freedom. An opportunity for social intercourse was afforded from six to seven o'clock for the renewal of old acquaintanceships and the forming of new ones, a feature regarded by some as one of the pleasantest of the evening. The large and handsomely furnished rooms adjacent to the banquet hall were admirably adapted for this purpose. It may be said that the Hardware trade have known each other without being acquainted; a seeming anomaly that will fast disappear under the influence of such reunions as the one just past.

The banqueting hall was arranged with seven tables besides the guests' table, seats at the latter table being assigned as follows:

CHARLES E. ADAMS.
JAMES H. KENNEDY.
PRODUCE EXCHANGE.
ARCHIBALD P. MITCHELL.
BRACE HAYDEN.
WEBSTER R. WALKLEY.
ANDREW S. UPSON.
THOMAS F. KEATING.
HENRY R. TOWNE.
EDWARD S. CLINCH.
REV. W. C. BITTING.
ST. CLAIR MCKELWAY.
WILLIAM H. WILLIAMS, President.
CHARLES A. MOORE.
OAKES A. AMES.
HON WILLIAM J. COOMBS.
COL. JOHN A. COCKERILL.
MAHLON J. WOODRUFF.
RICHARD R. WILLIAMS.
CHARLES L. MEAD.
WILLIAM H. HART.
DAVID WILLIAMS.
CHARLES MILLER.
GEORGE HENRY SARGENT.
HON. JOHN H. GRAHAM.

The absence of St. Clair McKelway, who it was expected would respond to the toast "The State," and from whom a letter was read; Congressman-elect John H. Graham, who is confined to his home by illness, and Geo. H. Sargent, whose previous engagement at the Harvard dinner prevented his attendance, was much regretted by those present. George J. Laighton occupied the seat assigned to Mahlon J. Woodruff, who was absent.

While dinner was being enjoyed the orchestra discoursed classical music and popular airs of the day, including selections from "Wang," "A Trip to Chinatown," and others, which struck so responsive a chord among those present that a large number joined in the chorus. At different times during the evening Ericsson T. Bushnell favored the company with vocal selections, which added much to the pleasure of the evening. His superb voice was greatly appreciated by all.

The dinner was an excellent one, and at its conclusion the toast list, which had been carefully prepared, was taken up. William H. Williams, president of the club, was a very efficient and acceptable presiding officer, and his speech of greeting was admirably adapted to the occasion and listened to with closest attention. Mr. Williams was especially felicitous in introducing the several speakers of the evening. It was a matter of congratulation that all the speakers, with the exception of St. Clair McKelway, whose absence is above referred to, were present.

After coffee had been disposed of and cigars lighted, Chairman William H. Williams called the assemblage to order and extended his greeting in a witty and eloquent address, at the conclusion of which he introduced Hon. William J. Coombs, who responded to the toast, "Trade and Finance." He was followed by the Rev. William C. Bitting, who spoke on Tubal-cain's place in life. The address was exceedingly clever, and amused the audience very much. Col. John A. Cockerill next spoke on the "Sword and Pen." He was followed by Charles A. Moore, who responded to the toast, "The Amenities of Business." Next, Henry R. Towne spoke on "Tendencies," Richard R. Williams on "Our Club," and at the end Webster R. Walkley of the Peck, Stow & Wilcox Company spoke in verse to the toast of "Sketches." The poem was excellently recited, and was greatly enjoyed by the audience. We print below the full text of this entertaining speech.

Mr. Walkley's Poem.

My theme is complex, a queer mixture of things,
A compound quite rare of which a Muse seldom sings.
How to fix it and mix it, and how best to serve it
To that body elect whom you know best deserve it
Is a difficult task at this stage of our meeting,
When wit has exploded, and the joy of your greeting
Has been dulled by much thinking and quite as much drinking—
While smoke is ascending the spirits keep sinking.
The tallest one, you know her name,
By daring deeds she won her fame;
A friend of truth in every age,
A guide to youth or wisest sage,

We saw approach; with lifted hand
She bade me come and join the band;
With parted lips in silver speech
She uttered truths that I would teach.

What is truth? Pray critic tell.
Canst thou weigh or measure well
This rarest gem in all the earth?
Dost thou know where it had birth?

If the truth thou wouldst seek,
Then thy lips the truth must speak;
If the truth thou wouldst know
Then the truth thy heart must show.

If the truth thou wouldst teach,
If some heart thou ear'st to reach,
If thou wouldst lead some trusting youth,
Thou thyself must be the truth.

Hardware, Implements of Iron and Steel,
Like swords and plows, the first men feel,
When in some Moses' hand it falls
To avenge a wrong in Israel's hosts or Pharaoh's halls;
Or when it cuts some Gordian knot that binds
A man or race of men. Freed, each finds
How sharp the edge, how keen the blade.
Of what Damascan stuff 'twas made!
As mighty as the pen—one made of steel—
Which throbs with life as throbs a steamer's keel.

In what a forge, in what a heat, were wrought
These mighty engines of our modern thought!
Progress, born of each, will cease to live
When swords are sheathed and pens no impulse give,
Each a mighty lever to uplist a sinking world,
And from decaying bastions have freedom's flag unfurled.
The sword oft cuts a way through mountains of despair,
And oft it hangs suspended by a single thread or hair;
It reeks with blood; it cries aloud from every battle plain,
Yet by the sword the world has reaped great gain.
It has been drawn for tyrants and for the oppressed unsheathed;
It has fought for Slavery, yet has Liberty bequeathed.
From plain of Askelon to Richmond's bloody field
It ever struck for Freedom when yeoman's hand did wield.
The Plow, almost as old as Mother Earth,
In times of Tubal-cain had birth.
Perchance was used in Eden's bowers,
Where beauty blushed mid sweetest flowers.
The upturned soil rich harvests bears,
Alike the rich and poor its bounties share.

In every age, in almost every race,
The Plow and Sword have symboled wealth and grace.
The corn of Egypt and the grapes from Eschol's vines
Are offspring of the Plow, as diamonds are of mines
By some translator's fault, I ween,
Or by some Hebrew points unseen,
The names of the men in the Hardware trade
Who sold the tools when the Ark was made
Are not recorded in Holy Writ,
Though Hammer and Nails, the Axe and the Bit,
Plows and Swords, Anchors and Chain,
Iron, Copper and Gold, which to our art pertained,
You will certainly find if you diligently read
The Book of Books, to whose counsels give heed.
There are the three Georges, at Sargent's, I mean,
And Tommy sits near, with Ladd in between.
He figures the discounts, adds and subtracts,
And has published a book to exemplify facts.
The others can multiply and often divide
The large profits on Locks, and Cottins beside;
They deal in all tools like the Axe, Hatchet and Hammer,
But the Head of the firm knows most about grammar.

And now with my guide we will walk down the street
And tell you of friends who perchance we shall meet.
Here is Laighton, who sits in a soft cushioned chair.
His hands, like Lamartine's, thrust through his hair,
Evidently solving some intricate problem
Concerning his customers (not how to rob them).
Scanning hexameters, his learning doth shame us.
"Tempora metantur et nos illis mutamus,"
Which, by the way, is exemplified here,
If you will just watch, as our guests disappear.

There is Smythe, so polite, and Germond, of great nerve,
Each vieing with each how best he may serve
The man who strays in to buy watches or clocks,
By changing his mind to want sheet metal Locks.
Men take no note of time, when in security they rest,
With these Locks upon the doors they dream of Araby, the blest.
The music of the tumblers as the key turns to and fro
Is sweeter than a chime of bells, ten thousand tell you so.

Clinch, a fine fellow, with Underhill near him,
Though the boys, it is said, most awfully fear him,
He has done what he could, and that as he would
To make this dinner the best—better than good,
With methods precise and a mechanic's devise
He keeps everything in strict order.
When he rides in the car he ne'er smokes a cigar,
Though sometimes he thinks that he orter.

There are Charlie and Abe, the Quackenbush boys,
Sharers of sorrows, yet many more joys,
With a host of kind friends in country and town
Feeling quite sad that their sign is pulled down.
There is John Graham, 'tis a pleasure to show him,
Honorable John Graham, as now you must know him;
He has carved his own way from poverty up,
And sips sweetest nectar from the winner's gold cup.
Hurrah! for our Congressman, honest John Graham!
A man of the People, he ne'er will betray them;
Right shall be Might and his honor kept bright.
Though the struggle be long,
In opposing the wrong,
After the night
Will surely come light,
And then the victor's song.

Peter McCartee, the pet of the street,
Always well dressed from his head to his feet;
A jolly good fellow, fair and square all around
The most popular man in the trade to be found

Have you heard of the firm, Smith, Bonsall & Field?
Sowing wide acres, expecting rich yield;
Selling Spades, Hoes and Rakes for planting the corn
To feed an on-coming race—children unborn.
Smith ever ready to bind up the sheaves:
The gleaners quite welcome to what Enterprise leaves.
There are Sickels and Sweet, with a Lyon to eat,
Though Sickels has garnered rich harvests of wheat.
Like bees in their hives, these earnest lives—
Still looking and struggling for meat.

What's in a name? As cunning as a Fox.
The phrase is not mine. Who's in a box?

There was William the Conqueror, and William his son;
Their race, we all know, is not yet run
William the Kaiser, and William the Great,
William the Prince of the Netherland State.
This William of Orange was Liberty's son,
Great and as good as our own Washington.
The light of these lives illumes history's page,
Which will ever grow brighter as time gathers age.
Sweet Williams that blossom in colors most rare,
And the Williams who sits in the President's chair;
The Williams who crown this occasion with grace,
Who spend time and thought to better their race,
Whose figures and fancies impress every page
Of the paper they edit and call *The Iron Age*.

Here are Kittredge and Kennedy, editors too—
What a host of fine fellows all pass in review—
In the van of the battle upholding the right,
Defending the truth with their pens and their might!

Here are Biddle and Bonbright, Irvin and Greeo—
The rarest of gems are often unseen—
And keen-eyed Supplee watching his chance
To always get in before an advance.

Have you read of Jack Horner who sat in the corner?
The name of the author I'm sure I've forgotten,
But the Plumb he secured through ill has endured
And other Plumbs has begotten.
They're all rigot, they sit here to-night,
With Hammer and Sledge and Pick for a fight.

There are a lot of good fellows all up through the State
Whose virtues and follies we surely can mate,
McCarthy so gracious, and Walbridge so cool,
And Matthews, most learned in Nature's own school.

Everson and Kennedy, Hamilton and Weed,
Men of culture and thought, sowers of seed,
Reeping rich harvest which Enterprise yields
To the tillers and toilers in life's fertile fields.

Barker, broad and square shouldered, upright and tall,
I'll say if I may, "the noblest Roman of them all;"
Brave, honest and true, a man through and through,
Unyielding, unbending, refreshing as dew.

There are Hibbard and Bartlett, with Spencer away
In a land which is fairer and brighter than day,
While Dezendorf sits exhausting his wits
How to buy better than they.
Conover square and Warren as fair,
While others are blowing
They keep a growing—
Lyford and Charles are still there.

Horton and Gilmore, McWilliams and Black,
With steam always up they keep on the track,
Not whistling and puffing for a mile in a minute,
Though if the race be close they'll surely win it.

Markley and Alling, Scoville and Crane,
Traveling through valleys, o'er mountain and plain,
Selling Sickles and Scythes for the old reaper, Time—
Their lives, like a song, in sweet melody chime.

Here are Sanford and Harvey, and Morley himself,
As cunning as mice nibbling cheese on a shelf,
Selling Lumber and Salt, Harness and Nails,
Old oaken Buckets and Leather-bound Flails.

The names we have mentioned, you'll agree, are the least—
The unnoticed the best, like the wine at the feast.

We drink to our friend, William J. Coombs,
The weaver of thought in the mind's great looms;
A builder of State, where the People are King
And the songs of the nation with Liberty ring.

We drink to our guests from pulpit and press,
Who always are striving some wrong redress;
Who stand with bows drawn, to shoot arrows of steel,
Yet ever found ready the wounded to heal.

We drink to that host, throughout our broad land,
Who toil with the brain or toil with the hand;
We welcome all climbers, and point to that light
Which alone they can reach by the ladder of Right.

We drink to the men who sell Iron, Steel and Nails
To lay the broad tracks or fasten the rails;
Who play with the lightning or harness the steam,
And awaken the age from its long troubled dream.

While I speak, the night wears on;
The morning star and rising sun
Will soon denote the day's begun—
The Birthday of our Washington.

This fading flower, whose breath perfumed the morning air, whose pe als kissed the dewy drops that night distilled, then gave promise of a life most beautiful and fair. Yester'eve the moon's pale beams and light of glimmering stars shone upon the open bud. At early dawn Aurora from her gilded couch looked across the Eastern hills and smiled upon its beauty. At sunlight's touch it blushed in crimson, as the water blushed at Master's voice at wedding feast in Cana. Painted by a hand divine, in colors rich which limner's brush nor art can trace. Ere the noontide hour, plucked from the parent stem through which it drew its breath, it lost its life and power, yet in dying yields sweet fragrance. O! simple flower, thy life of but a day shall teach us, pilgrims on the way, by grace of speech, by purity of thought and life, by kindly deeds of charity and love, to yield sweet fragrance like thyself.

At the conclusion of Mr. Walkley's poem, which was listened to with the closest attention, the president introduced Hon. Charles E. Mitchell, ex-Commissioner of Patents, who referred in a brief speech to the important part which the American patent system has had in the development of the country and its manufacturing interests.

At the conclusion of Mr. Mitchell's remarks, which were appreciated by the company and heartily applauded, the president dismissed the assemblage by quoting the sentiment from Ben Jonson with which the toast list closes:

In the hope to meet
Shortly again and make our absence sweet.

Officers of the Hardware Club.

WE GIVE on an accompanying page portraits of the officers of the Hardware Club of New York. These gentlemen are as as follows: William H. Williams, president; K. H. Swayze, vice-president; Thomas F. Keating, treasurer; and J. L. Varick, secretary. The gentlemen mentioned were very active in organizing the Club, and we take pleasure in giving below sketches of their business careers, which will doubtless be of interest to the trade:

WILLIAM HILTON WILLIAMS.

William Hilton Williams was born in Schoharie County, N. Y., November 7, 1847, of New England parentage, being descended in the ninth generation from Robert Williams of Norwich, England,

who settled in Roxbury, Mass., in 1638. Mr. Williams came alone to New York in quest of fortune in March, 1862, and found employment with Brooks Brothers, clothiers, of Catharine street, and was in the store when it was sacked by rioters in July, 1863, and did military duty during all that turbulent week. In 1865 he entered the Cutlery and Commission Hardware house of Clement, Hawkes & Maynard, at 14 Beekman street, and subsequently entered the employ of J. Russell & Co. In 1871 Mr. Williams formed a partnership with Cornelius S. Van Wagoner, with whom he has ever since been associated in the manufacture of Hardware. The two are brothers-in-law, having married daughters of Edward E. Bowen, an old and highly respected merchant of New York and resident of Brooklyn. The business of Van Wagoner & Williams was conducted for many years at 82 Beekman street, New York, but in 1892 the firm (which had been recently incorporated) removed their factories to Cleveland, Ohio, retaining New York headquarters at 14 Warren street. Mr. Williams is well known to the wholesale Hardware trade of the East and West, having traveled extensively in the prosecution of his business for many years. He resides on Prospect Heights, Brooklyn, and has a summer home at Woodstock, Conn., where his ancestors came from.

Mr. Williams has been somewhat actively identified with the social and political life of Brooklyn for 20 years. He was elected president of the Brooklyn Young Republican Club during the memorable Blaine campaign of 1884, and held that office until after Mr. Harrison's election, has been several times tendered the Republican nomination for Mayor of Brooklyn, and Mayor Chapin wished to appoint him one of the Civil Service Commission, but he has always declined political office. He was a delegate to the Republican State Convention of 1891, where he nominated General Woodford for Governor, and was chairman of the Executive Committee of the State League of Republican Clubs in 1888.

Mr. Williams is president of the Brook-

The Officers of the Hardware Club of New York.

lyn Choral Society and corresponding secretary and a director of the New England Society. He is a member of the Young Republican, Montauk, Hamilton and Union League clubs of Brooklyn, and is also connected with other social, military and business organizations.

Despite his activity in social and political organizations Mr. Williams is a careful, energetic and exact business man, and few men are more diligent in the attention given to their business.

ROBERT H. SWAYZE.

Robert H. Swayze, the club's vice-president, is the secretary of the Plume & Atwood Mfg. Company, a representative concern in the manufacture of Brass and Copper goods. He has been associated with this company since 1885, and is now in charge of the business in this city. Mr Swayze has given much time and effort in the way of promoting the interests of the club and is a valuable acquisition to its roll of members.

THOMAS F. KEATING.

Thomas F. Keating was born in Pittsburgh in 1845, his parents having been among the early settlers in that city. Mr. Keating attended school until he was 16 years old, when he went to work for the firm of John Dunlap & Co., manufacturers of Stamped and Japanned Tinware, in that city. His first work was on a screw press, edging fruit can tops and bottoms at one cent per gross. Mr. Keating was subsequently graduated to the store, where he was made successively packer, porter and assistant shipping clerk. Four years were thus spent and then Mr. Keating engaged in the real estate business for about a year, when he received an offer from the contractor on the Hoosac Tunnel and Troy & Greenfield Railroad in Western Massachusetts, and entered his employ as bookkeeper and paymaster, with headquarters at Shelburne Falls, Mass. It was here that he made the acquaintance of the Messrs. Yale, as the lock factory was then located at that place. He spent two and a half years with Mr. Farren, and in 1869, entered the employ of the Yale Lock Mfg. Company, their New York office being at that time at 1 Barclay street, as their traveling salesman. His first sale of a Yale Lock was to Jos. Woodwell & Co. of Pittsburgh. The territory he covered embraced the United States and Canada, and his trip usually occupied the entire year. With the exception of about six months when he was in Boston handling the Time Lock trade, Mr. Keating spent nine years on the road. In 1878 he assumed the management of the Company's New York office at 53 Chambers street, and in 1880 he became a stockholder and director in the company. Mr. Keating is at present assistant treasurer of the company and manager of its New York warehouse, which is now at 84 and 86 Chambers street. Mr. Keating is married and has two children. He resides at 317 West Twenty-third street.

J. LEONARD VARICK.

J. Leonard Varick, the secretary of the Hardware Club, who has done yeoman service throughout the various stages of its organization and incorporation, was born in Poughkeepsie, N. Y. Graduating from Yale College, Class of '68, he connected himself with the Union Nut Company in New York in March of the following year, and has been with the company ever since, now filling the position of assistant treasurer. Besides being a director of the Miller's Falls Company he is identified with the following social organizations, viz.: The University Club, Colonial Club, Yale Alumni Association of this city and the Holland Society of New York.

Attractive Show Windows.

Successful hardwaremen, as well as those engaged in many other lines of similar business, says a correspondent, have come to recognize the fact that the art of window dressing is one which ought to be given a great deal of consideration. It has been the experience of the writer that those hardware stores which make an effort to attract the attention of the people profit thereby.

This is the age of display. Everything goes to prove the correctness of this statement. A good window display is good advertising, if that term can be used to express its effect. There are two hardware dealers, we will say, for illustration, in a certain city or town. One has a big stock, but it is all jumbled up together. Not only is there disorder, in fact, practically chaos, but there is also an ancient air about the place, sort of an "old curiosity shop," as it were. The dust here and there is sufficient evidence that something or somebody is behind the times. You might have passed by the store a year ago and the window would look familiar now, but the chances are that you would not take the trouble to look at it, unless intuitively or without being aware that you were so doing.

Unless somebody has been into the establishment to purchase a rat trap or fire shovel, the only one of which in stock was in the window, there has been no change, and the absence of the rat trap would scarcely be noticeable. If you asked the proprietor why he did not dress up his window he would probably inquire what was meant. Truly he sells something once in a while, probably enough to live on. He may be a very friendly sort of a man, too. Those who patronize him do so because they know him. But those who know him will pass away in time.

We come to another kind of a hardware store not many blocks away. The very contrast makes it noticeable. There is an air of the hustler about it—and the word "hustler" is a very good one to use in reference to the business men who are making a success. The second hardware store has no cobwebs about it. Everything in and concerning it is bright and attractive. Ten chances to one there is not so much stock in it, either, as there was in the first store. But there seems to be more. We go in and look around. Perhaps we did not want to purchase anything when we went in, but we see some sort of a useful device or article that is "just the thing," and we buy it. It is absolutely a pleasure to look around at the well-arranged and "up to the times" stock which Hardware Dealer No. 2 has put in, and not only put in but kept bright and shining. We see a number of articles which we make up our minds to purchase later. We are very well pleased with this hardware store.

But now the main point in this little informal argument is reached. What was it that brought us into hardware store number two? What was the magnet that attracted? The answer is a very simple one, when you stop to think a moment.

When we passed hardware store number one, we were not even drawn to note it particularly, and probably could not have told a moment after having passed it that we had actually passed it. But what drew us into the second hardware store was an attractive window. In that window the goods had some degree of an artistic form of arrangement that attracted the eye, and where the eye went the purchaser followed. The well-dressed window was the secret of the whole thing. It did what it was intended it should do, as far as we were concerned, and will probably do the same many times again. Perhaps to-morrow or the next day the window will be put in another attractive and new dress. There may not be a single new article used, either, but the man who runs that hardware store is an artist in his way. He will get trade wherever he goes.

Steel Shop Box.

The Shop Box shown herewith is offered by the Avery Steel Mfg. Company, Forty-third street and Stewart avenue, Chicago, Ill. The box, including body and handles, is made of one piece of steel, turned on the upper edge, and is provided with an aperture at each end for the insertion

Steel Shop Box.

of a hook for moving it around the shop. The boxes are made in three sizes, from 18 to 21 inches long, 10 inches wide and 5 inches deep, of 16 and 18 gauge steel. They are designed for use by nail mills, bolt and nut works, &c., for handling the small stuff about their works.

MEMORANDA.

LLOYD PADDOCK, the Preston Hollow, N. Y., hardware merchant, who is also postmaster, is about to enlarge his establishment and add a large building to it. He also expects to have a first-class tin shop, and will enlarge his store, and his stock will be increased.

L. V. GARDNER of Centreville Station, N. Y., is making a number of improvements in his hardware store, enlarging it and adding new features. He has secured the services of George J. Warren.

HENRY J. FEGAN, dealer in hardware at 14 Palisade avenue, Yonkers, N. Y., died suddenly on Wednesday evening, February 15. Mr. Fegan was the youngest of four brothers, the oldest of whom started a tinware business on the premises now occupied by the City Hall Hotel in 1850. The venture proving successful, he was subsequently joined by his three brothers. They purchased the land at 14 Palisade avenue and erected a three-story brick structure, where the hardware business has since been conducted.

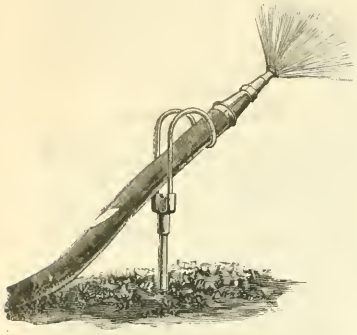
A financial writer remarks: Where the country is drifting in the matter of its currency is forcibly shown by comparing the ratio of note obligations payable in gold to the gold available for their redemption February 1, and upon the date nearest that of the Sherman silver act:

	July 1, 1890.	February 1, 1893.
Note obligations	$346,800,000	$474,800,000
Net gold in treasury...	19,500,000	108,200,000
Ratio gold to notes....	55 per cent.	23 per cent.

The gold balance has fallen 43 per cent., while the note obligations have increased 37 per cent,, all on account of the issue of $128,000,000 notes under the law of 1890.

Gem Nozzle Holder.

Gibbs Mfg. Company, Canton, Ohio, are putting an improved form of their Gem nozzle holder for sprinkling lawns on the market, as shown herewith. It is made of malleable iron and spring-steel wire, galvanized to avoid rusting. It is remarked that the hose is held firmly in the holder and can be adjusted to any elevation in an instant without the annoyance of thumb nuts or other contrivances. The



Gem Nozzle Holder.

point is made, that with the use of the holder water can be thrown where wanted, the position of the nozzle changed as desired without shutting off the water before approaching it, or without having to pass over wet grass, and that on small or narrow strips of lawn and garden the stream is directed to any desired point without splashing water upon other surfaces.

Improved Acme Steam-Jacketed Kettle.

The kettle herewith illustrated is manufactured by the Stuart & Peterson Company, Philadelphia, Pa., which embodies

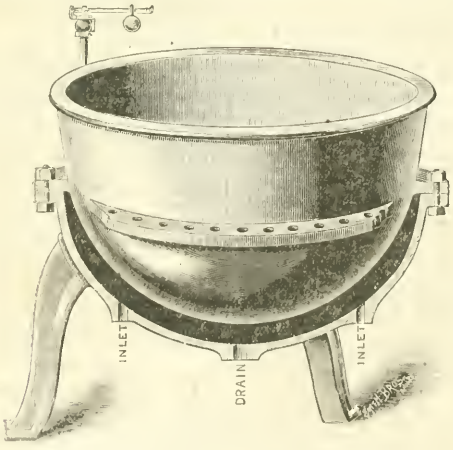


Fig. 1.—Improved Acme Steam-Jacketed Kettle.

improvements for this class of kettles. The point is made that the boiling commences midway or near the bottom, resulting in uniformity of the boiling process, obviating the boiling at the top and boiling over with other unsatisfactory results. The kettles are furnished with or without safety valves, the valve cut off to 60 pounds. The kettle is cut away in Fig. 1, showing the interior construction and the hight of the jacket, while Fig. 2 gives a sectional view. The kettles are designed for the use or butchers, canners, chemists, confectioners, curriers, hotels, paper manufacturers, printers, public institutions, soap manufacturers, varnish makers, &c., and are made in 10, 13, 24, 43 and 52 gallon sizes.

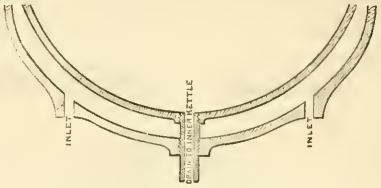

Fig. 2.—Sectional View of the Kettle Bottom.

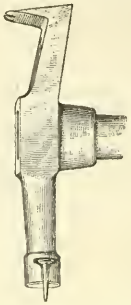
The Richardson Tack Hammer.

Smethport Machine Company, Smethport, Pa., are offering the hammer illustrated herewith. A feature of the hammer is the peculiar shaped claw, the angle of which is such that a tack may be removed by simple downward pressure, and will remove closely driven tacks without injury to the base board or the surrounding wood work. The steel claw is ground to a sharp edge, and the manufacturers state that they will replace any hammer on which the claw has been broken by legitimate use. One grade of hammer is magnetized, and has a recess in the head corresponding in shape to a tack. This grade or style is designed for ceiling work, and for driving tacks where only one hand can be used. The unmagnetized grade is designed for all other kinds of work. The manufacturers remark that the hammer is perfectly balanced, and has a fine round handle, and, while not highly finished, is strong and durable, and a superior tool for a cheap hammer.



The Richardson Tack Hammer.

Murrin's Hat Rest.

The Murrin Hat Rest Company, 1515 South Jefferson avenue, St. Louis, Mo., are offering this article as shown in the accompanying cuts. The points of excellence claimed by the makers for the rest are that the hat is positively and firmly held, and not allowed to sway to the right or to the left; that the hat cannot come off, as its own weight locks it automatically between the upper and lower bars; that the hat when lifted to a horizontal position, goes off or on with ease; that there is nothing to catch and tear the lining of the hat, and that with a silk hat it is impossible to ruffle the fur in going on or off. The point is made that it preserves the shape of a hat in its original contour, and the hat is saved from the innumerable tumbles the ordinary hook inflicts, keeping it in shape to a good old age.

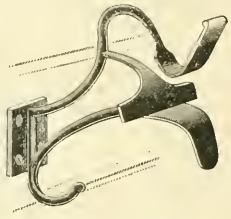


Fig. 1.—Murrin's Hat Rest.

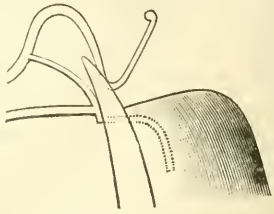

Fig. 2.—Hat Rest in Use.

THE FIRM of Van De Water & Burtiss, dealers in stoves, tinware, etc., at 152 and 154 Jay street, Schenectady, N. Y., have dissolved copartnership. Robert J. Van De Water has retired, and the business will be continued by Albert R. Burtiss. Mr. Burtiss is popular and has many friends who wish him success in continuing the progressive establishment.

Challenge Refrigerator Lock.

The refrigerator lock, the parts of which are shown in detail in the accompanying cuts, is made by the Challenge Corn Planter Company, Grand Haven, Mich., for whom B. B. Neal, 106 Chambers street, New York is agent. It is used only on their refrigerators. It is pointed out that the operation of the lock is the same as an ordinary spring bolt lock in opening and closing the door, with this addition, that a slight turn of the knob after the door is closed draws the door to a close, tight joint. The manufacturers claim that the lock is strong and durable, that the locking bolt catches automatically when the door is closed without the use of the hands, and that it has the qualification of easily drawing the door to a close, tight joint, thus preventing rattling and the escape of the cold air from the provision chamber.

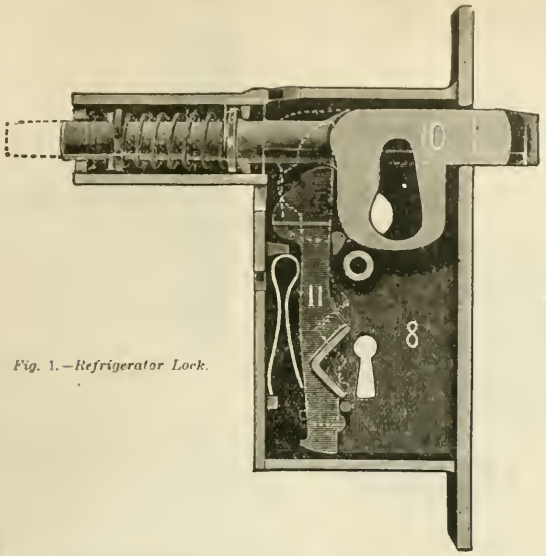

Fig. 1.—Refrigerator Lock.

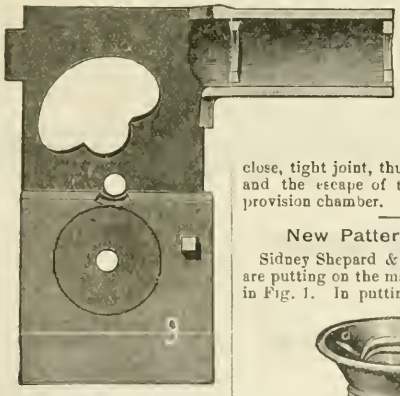

Fig. 2.—Lock Cop.

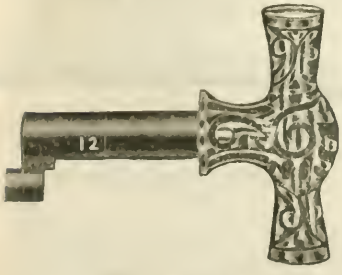

Fig. 3.—Handle of Lock.

New Pattern Milk Can.

Sidney Shepard & Co., Buffalo, N. Y., are putting on the market the can shown in Fig. 1. In putting the parts together, Figs. 2 and 3, the body is riveted in the side seams, and breast and bottom are offset, forming shoulders upon which the body rests. The shoulder on the bottom is designed to give support to the inside hoops and the body, making it, it is stated, impossible for the rivets to be sheared off in rough usage, or the soldered joints to be broken by the can being thrown down. The edge of the breast is folded completely around a reinforcing half-round rod, the whole overlapping the edge of the body. The cans are furnished made up, or the stock complete, with the bodies squared and punched, to be constructed in the tin shop. The can is especially designed to supply the demand for a cheaper can than their Buffalo milk can. The manufacturers remark, however, that by means of patent devices they have been able to secure a strength and resistance which renders this can unusually serviceable.

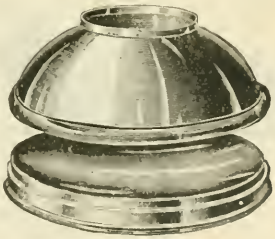

Fig. 3.—Breast and Bottom.

Avery's Never-Leak Steel Hods.

The accompanying illustrations represent hods manufactured by the Avery Steel Mfg. Company, Forty-third street and Stewart avenue, Chicago. The hods are made from one piece of 18-gauge steel, reinforced on the edges and at the dumping

Fig. 1.—Never-Leak Steel Mortar Hod.

point, the ends of the bodies being fastened together by a peculiar method. The fork and shoulder saddle, as shown in Fig. 1, is of malleable iron, to which cloth may be attached if desired, on the under side

Fig. 2.—Mortar Hod with Wrought-Iron Fork.

of the saddle. The socket is arranged to hold the hardwood handle, and to take up any shrinkage; or to replace a broken handle. In Fig. 2 the forks are made of wrought iron and the shoulder saddle of

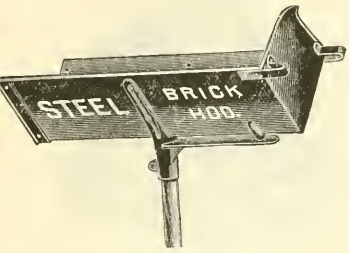

Fig. 3.—Steel Brick Hod.

wood, these being attached to the body of the hod, as shown in the illustration. Hardwood handles are also used with this hod, and broken handles may be replaced. The manufacturers claim that the hods are water tight, and are 25 to 50 per cent. lighter, when in use, than the common wooden hod; also, that the malleable iron fork and shoulder saddle make it easier for the user to carry. The brick hod shown in Fig. 3 is made with malleable-iron fork and shoulder saddle, also with wrought-iron fork and wood saddle, as in Fig. 2. The hods are furnished either black or galvanized, and are shipped knocked down.

Nonpareil Ratchet Wrenches and Combinations.

The Keystone Mfg. Company, 312 Terrace, Buffalo, N. Y., are introducing these goods, which are illustrated in the accom-

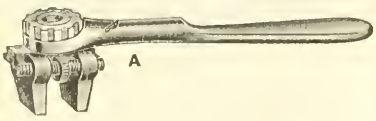

Fig. 1.—Nonpareil Ratchet Wrench.

panying cuts. These tools are described by them as made of the best material, highly polished and nickel-plated throughout and of excellent mechanical construction. The tools are designed to be used in combination; combination No. 1 including those shown in Figs. 1, 2, 3 and 4, except that only two of the sockets in Fig. 4 are included in the price for the combination. Socket B, Fig. 4, is for screw-driver bit or reamer shank and is used with the wood handle, Fig. 2.

Fig. 2.—Wood Handle.

Socket D, the bottom one shown in Fig. 4, is for drill shank and is used with the feed nut, Fig. 3. The center socket in Fig. 4 is for Morse taper shank drills and is used with feed nut, Fig. 3, but is sent only when ordered. The socket attachments are made to take different sizes of bit, drill and reamer shanks, and are quickly and easily adjusted in the wrench. The wrench, Fig. 1, is 9 inches long, having jaws which open from $\frac{3}{16}$ to $1\frac{1}{4}$ inches, ad-

Fig. 3.—Feed Nut.

justed and regulated by a right and left screw by means of the thumb nut A, with right and left hand ratchet. The shank of the socket is passed between the jaws of the wrench and up through the circular hole in the ratchet plate, when the jaws are closed firmly with the thumb nut A. The top of the jaws are thus brought under the shoulders of the socket, firmly locking the attachment in the wrench. In using socket B, Fig. 4, the wood handle C is placed upon the socket and the thumb nut screwed down, thereby securing it while in use, as shown in Fig. 5. In using the

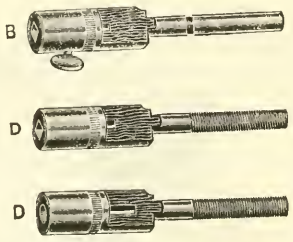

Fig. 4.—Bit and Drill Sockets.

drill attachments D, either square or Morse taper, the socket is attached in the same manner, but the feed nut, Fig. 3, is screwed down on the socket, forming a complete drill, Fig. 6. The wrench may be made reversible instantly without removal from the work simply by throwing over the lever in the slot of the handle, which changes the direction of the ratchet.

The wrench may be used by itself for hexagon and octagon nuts, and also for square nuts. The combination, Fig. 5, may be used to advantage in many places as a wrench for small nuts; for instance, on the nuts inside of wheel felloes, &c. The tools can be used successfully at almost any angle, or in any position, and are referred to as being adapted to the uses of engineers, machinists, boiler makers, electricians, plumbers and gas fitters, millwrights, agricultural implement manufacturers and dealers, carriage and wagon makers, wood workers, &c. Owing to the peculiar and improved mechanical

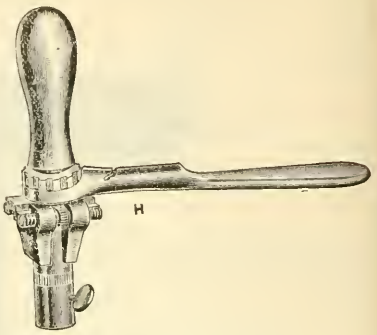

Fig. 5.—Bit Socket and Handle Combined.

construction of the tools, the manufacturers claim a great degree of strength, durability and latitude of usefulness, with handsome finish. A combination, known as Mammoth No. 5, is made similar to combination No. 1, only larger, constructed especially for heavy work, such as boiler making, bridge building, &c., and general heavy machine work. Combination No. 3 is wrench, Fig. 1, with a

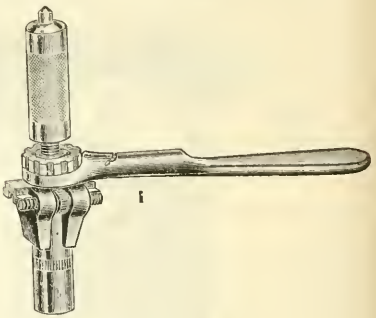

Fig. 6.—Drill Socket and Feed Nut Combined

drill attachment, feeding with a screw instead of a nut, as in No. 1 combination. It is designed especially for light work in limited space, and is furnished with a square socket only. The round jaw, No. 2 wrench, Fig. 7, without combination, is intended especially for use on axle nuts of carriages, buggies, wagons, &c., also

Fig. 7.—Round Jaw Nonpareil Ratchet Wrench.

for the various requirements of all agricultural implements and machinery and for domestic purposes. The jaws of this wrench are adjusted the same as Fig. 1, and the wrench is also made in a No. 5 round jaw, on exactly the same principle as Fig. 7, only of increased size.

STOVE TRADE NOTES.

Misleading Directions.

From T. I. P., *Springfield, Mass* — By carefully studying all of the ideas advanced in my line I have been able to find the true cause of many effects and successfully avoid their consequent annoyances. Nothing that I have read of late has so impressed me as capable of possible harm as some of the laws laid down in the two circulars, for the benefit of stove dealers, prepared as the result of special provision made at the last Convention of the National Association of Stove Manufacturers and appearing in the last issue of *The Metal Worker* under the head of "Chimneys and Drafts in Operating Stoves." In my opinion the last assertion in the circular entitled "Directions for Operating Stoves," given below, is far from correct:

"It is possible that the draft of the chimney is so strong as to carry the heat so rapidly round the oven as not to be absorbed by the plates, and the oven fails to heat sufficiently from that cause. A damper in the pipe will relieve this."

All of my force think this pretty rank, yet, when it is the result of a special provision of the National Association of Stove Manufacturers for a preparation on the subject, some credence must be accorded to it. If that body will set up a cooking stove in the foundry of one of its members and arrange to connect it with the blower to the cupola, the wind will be sent through that stove faster than any chimney will make it go. If a good fire is built in this stove and care is taken to get a good solid body of live coals either from hard or soft coal, coke, corn cobs or wood and the blower started, "the plates will absorb the heat" so quickly as to blister your finger in a few seconds after the blower starts and will continue to absorb and blister the faster the blower blows until the contents of the fire chamber are all blown clear around under the oven, and won't cease to absorb and blister until the coals are blown clear out of the stove if the blast is strong enough, the current fast enough and lasts long enough. Such a trial would demonstrate my opinion to be wrong or the fallacy of the authority which produced and presented such a rule.

I believe no draft can be too strong which can be controlled and prevented from overheating. In an ordinary chimney often the draft is so strong that the bottom of the oven is so hot that bread will burn on the bottom and fail to bake properly. The housewife prevents this by closing the drafts in front and setting the bread upon an ordinary sad-iron stand so it does not come in direct contact with the excessively hot plates.

The damper in the pipe, as suggested, will help to prevent overheating, but will never help to heat.

This rule would tend to create an impression that some chimneys are too good rather than impress the fact that most chimneys are too bad, as the second circular suggests in stating, "There are more bad chimneys than good ones."

The second circular, which has the approval of the same authority, sets in a separate sentence, as an assertion, the following:

"A stove can no more operate without a chimney than a steam engine can operate without a boiler."

If the word "operate" with the stove meant do its best, and the word "good" was inserted before chimney it would be more nearly correct, but as it is, it is all wrong, and leaves this impression on the mind of those who have yet to accumulate an experience. The chimney, like all chimneys, is claimed by its owner to be good, consequently if the stove don't work the whole fault must be with the stove, especially if all the other suggestions of the two circulars have been complied with, which is, of course, all wrong. Letters from members of this very body have told us when a stove would not work at a chimney to take the stove out of doors and impress on the buyer that the stove would do spendid service when not hampered by a bad chimney. This shows that some makers do not believe a chimney is as essential to a stove as a boiler is to an engine, to which it is indispensable.

Stoves giving excellent results when standing out of doors with no other chimney than a piece or two of pipe refute the assertion positively and can be found in any community. Some of the other rules differ from my experience and practice, but as they are not likely to create wrong impressions that may cost the dealer dollars by leaving second-hand stoves in his stock, they do no harm. Aside from these criticisms the circulars are as capable of good as their intent.

If such a step had been taken years ago many a dollar would now be resting where it ought to be, instead of having been wasted through the unnecessary expense caused by the lack of this information.

ODD PLATES.

THE STOCKHOLDERS of the Dighton Furnace Company, North Dighton, Mass., held their annual meeting on February 15 and elected S. N. Staples, president; F. P. Leonard, agent and treasurer, and J. F. Dunlap, clerk. These officers, with A. W. Parker, Lewis Williams and H. M. Staples, constitute the board of directors. The salesmen of the company are A. J. Dunlap, Frank K. Frost and F. P. Leonard. We understand that the company have under construction some new patterns which will surpass anything that they have ever before attempted.

THE ART STOVE COMPANY of Detroit, Mich., have just completed the purchase of additional property on Milwaukee avenue, on which they propose erecting a new foundry building. The improvements contemplated cover a new foundry building 257 feet long by 128 feet wide, to be erected in the most substantial manner and to be equipped with all modern improvements. The plant of the company now fronts on Russell and Rivard streets, Milwaukee avenue and the Boulevard.

THE CORTLAND HOWE VENTILATING STOVE COMPANY of Cortland, N. Y., issue an announcement to the effect that, it having come to their knowledge that certain persons have visited different places in New York and other States, with the avowed object of locating a branch of the company named, or to organize a company for the manufacture of the Howe ventilating stoves, they desire to say that they are not contemplating a removal or the locating of a branch of their works in any other place. They also state that no one has been authorized to act for them in any business having such an object in view. They emphatically declare that they own and control, absolutely, all patents under which the Howe ventilating stoves are, or ever have been, made, and that they will not permit the manufacture of their stoves by any other company, the infringements of their patents, or the violation of any of their trade rights.

THE DIFFICULTY between the Clinton Foundry Company of Troy, N. Y., and their molders, in regard to prices on some new work, has been left to the officers of the International Executive Committee of the Molders' Union to adjust. It is understood that everything will be satisfactorily settled.

THE PORTSMOUTH STOVE & RANGE COMPANY of Portsmouth, Ohio, refer to their Model wrought-steel range as possessing many valuable features, and as meeting with a very gratifying reception at the hands of the trade. It is provided with patent oven door device and an improved fire box, which is so arranged that the ashes cannot back up and burn out the linings after being in use for a short time. The company are also producing a line of hard cold-steel ranges with duplex grate and tile linings, together with an assortment of goods having incased low-down reservoirs.

AT THE ANNUAL MEETING of the stockholders of the Fuller & Warren Warming and Ventilating Company of Troy, N. Y., Gordon G. Wolfe, Wiltsie F. Wolfe and William Henry Warren were elected directors for the ensuing year. Votes representing 1000 shares of stock were cast.

AT A RECENT MEETING of the stockholders of the Excelsior Mfg. Company of St. Louis, Mo., Giles F. Filley, Charles F. Filley, Frank Filley, Robert E. Filley, and George D. Dana were elected directors.

ACCORDING TO A RECENT ISSUE of the Taunton *Gazette*, White, Warner & Co. of Taunton, Mass., are making preparations to enlarge their works. We understand that 30 hands are now given employment, and that the increased capacity will provide room for double this number, and for the turning out of 50 stoves a day.

J. S. VAN BUREN, head designer and chief of the pattern department of Rathbone, Sard & Co., Albany, N. Y., was recently awarded several prizes on photographs exhibited at the show of the Albany Camera Club. He is one of the prominent members of the club.

THE BACKUS MFG. COMPANY of Williamsport, Pa., have leased one of the stores in the new Yates building at Syracuse, N. Y. They have filled it up with a handsome line of their heaters, of which there are said to be over 9000 now in use. Gas is the fuel used, and the construction of their grates and mantels is very artistic in design. Mr. Lottingham is the manager of the Syracuse branch.

THE PERRY STOVE COMPANY of Albany, N. Y., have resumed operations at their extensive plant on the island below that

city, having completed repairs and inventory. Superintendent Liddle says there is every indication of a good year's business. A healthful feeling seems to prevail among the trade generally, auguring a profitable year. The company have some new goods in preparation which they hope to be able to offer the trade in the near future. They started in this year with more men than they did last and are satisfied with the outlook.

GEO. H. BARBOUR, vice-president and general manager of the Michigan Stove Company, Detroit, accompanied by Mrs. Barbour, has gone to Florida to spend a month for the benefit of his health, which has been slightly impaired by a severe cold, contracted several weeks ago. During his stay in the South he will visit St. Augustine, Tampa Bay, New Orleans and other leading points of interest.

THE NATIONAL VAPOR STOVE & MFG. COMPANY of Cleveland, Ohio, are offering the New Idea vapor stove in an improved form for 1893. In referring to this construction, the manufacturers state that there is no smoke in lighting, no odor when running or extinguishing the burners, and that the latter can be readily lighted by any one. It can be easily taken apart, even to the burner, by the use of a screwdriver. The principle involved is the same as that embodied in last year's construction, but the operation is somewhat different. The manufacturers state that their regular line has also been improved, and that they have ready for the trade a high and low junior stove of new construction embodying many features of merit. They state that on account of the extreme cold weather they have been delayed in getting into their new works, and so will continue manufacturing in their old establishment until they can move without detriment to the trade.

ANOTHER PUZZLE has been issued by the indefatigable puzzle maker of the Michigan Stove Company. This time it is a diagram representing a prison containing 36 cells, connected with each other by doorways. The puzzle is how to get from a corner cell to the one diagonally opposite, entering each cell but once. The key is not published on the card, but is furnished on application to the Michigan Stove Company. The reverse of the card is devoted to a very pretty picture of childhood, lithographed in colors.

WE LEARN that E. J. Cridge, recently associated with the Michigan Stove Company, Detroit, Mich., has severed his connection with that concern.

THE PETITION of Judge John Gutmann, receiver of the property of the Albany Stove Company, Albany, N. Y., to sell the concern's effects has been granted by Supreme Court Justice Herrick. The receiver recites in his petition that by an order of the Supreme Court of November 29, 1892, the Albany Stove Company were dissolved and the petitioner appointed receiver. The company own real estate in Albany consisting of a foundry, mounting shop, engine room, storage room, pattern shop, office and manufactory. Claims against the company for $19,500 have been filed. There is a mortgage on the real estate held by James H. Carroll, ex-president of the company, and John W. McNamara, for the sum of $10,000, to secure them to that amount as indorsers of certain notes which are now part due, the amount being included in the $19,500 debts. The receiver stated in his petition that he considered it advisable to dispose of the property as far as possible as a whole and not piecemeal. The order to sell requires the receiver to give 14 days' notice of such sale. It seems to be the opinion that the excellent and practically new plant of the dissolved Albany Stove Company will be taken up by some enterprising men here and again put in operation. The concern have splendid facilities for making stoves.

A Unique Advertisement.

Among the enterprising stove concerns in the Northwest is the firm of Evenson Bros. of St. Peter, Minn. The members evidently believe in the use of printers' ink, and endeavor to put what they have to say before the public in a manner to attract their attention. In a recent issue of the St. Peter *Herald* is presented an advertisement decidedly unique in its way, and which we consider of sufficient interest to reproduce herewith. It may contain suggestions and convey hints of value to others engaged in the stove business.

Test of an Open Gas Fire.

In a late issue of the *Gas World* was reprinted a record of a test of an open gas fire made by B. H. Thwaite, and concerning which he says:

The following is a record of a careful test to determine: 1. The efficiency of the gas fire in transmitting the heat produced. 2. In establishing an equable temperature. 3. To ascertain the cost in gas to heat a given volume of air. The date of the test was October 10, 1892—a sunless, autumn day. The gas was the ordinary 15 75 candle power quality, and was introduced to the gas fire at a pressure of $\frac{13}{16}$ inch of water. The rate of consumption was 22 cubic feet per hour. The test was conducted in a room, Fig. 1, of the following dimensions: Internal length, 18 feet 6 inches; internal breadth, 13 feet; and internal hight, 11 feet 5 inches; cubic capacity, 2765 75 cubic feet. Two sides and part of the third side of the room are outside glazed walls, exposed to the atmosphere—these walls being built up of timbering. In the room there were sundry benches and tables, and parts of gas lamps, a photometer and a small gas holder. The rate of flow of the gas was checked by an accurate standardized meter, equipped with a pressure gauge. Ordinary Fahrenheit graduated mercury thermometers were placed at various positions in the room, to determine the uniformity of heating of the system. The zone of combustion was 1 foot 6 inches above the floor, the gas fire being raised to this extent. The products of combustion were delivered outside the room by means of a 4 inch diameter tube. Thermometers were also placed externally. It was intended to determine the flow of air into the gas fire, but the anemometer indications were untrustworthy, owing to the imperfection of the instrument. Two persons were in the room during the test, the duration of which extended from 2.20 p. m. to 5.10 p. m.

Temperature Determinations.—To obtain an adequately accurate judgment of the heating effect, the temperature was registered at 16 points on four semicircles drawn around the gas fire, the front central face of which formed the center of the semicircle. Besides the positions named, temperatures were observed at varying heights of 2 feet, 4 feet and 5 feet, respectively, above the floor level. Determinations were also taken near the ceiling, and on the inside of the three walls at the hight of 8 feet from the floor level. There was not any firing back at any of the times when the gas was suddenly extinguished. The appearance of combustion and of the refractory lumps was almost ideally like an open blazing coal fire, and the temperature opposite the front face of the fire was even too hot to be comfortable. The efficiency of the gas fire, measured according to Carnot's law, varied between the two limits of 196° and 256° final temperature. Accepting 2000° as the temperature of combustion, the calculation of Carnot's law gives the efficiency of 80 per cent. in one instance, and 90.5 per cent. in the other. The results are shown graphically in Figs. 2, 3 and 4.

Actual Expenditure of Gas.—This equaled (2 66 hours by 22) = 58 52 cubic feet. If we take the thermic value to be 700 units per cubic foot, the expenditure runs up to 700 × 58 52 = 40,964 units.

We will now approximately determine the distribution of this heat. (No allowance is made for the human absorption of heat, because the general temperature never exceeded that of blood heat). If we take the average final temperature of the air to be 80° F., then the increase of heat from 59° initial temperature would be 80° − 59° = 21°.

Then 21 × 2765 75 = 58 080 75,

and taking 0.2375 as the specific heat factor of the air, the absorption equals 13,795.

$$\text{Then } \frac{13\,795 \times 100}{40,964} = 33.6 \text{ per cent.}$$

Proportion absorbed in waste gases—

$$\left(\frac{190 + 250}{2} = 220\right) - 59 = 161°, \text{ then}$$

$$161 \times (58.52 \times 5) \times \underset{\text{sp. ht.}}{0.2230} = 10,505.$$

The percentage loss

$$= \frac{10.505 \times 100}{40,964} = 25.6.$$

Recapitulating, we can now ascertain the exact proportion of heat absorbed in raising the temperature of air insensibly flowing through the room and in addition to that required for the combustion of the gas. This equals

$$(13,795 + 10,505) - 40,764 = 16,664$$

Now, as a proportion of this heat was wastefully absorbed by raising the temperature of the air above 80° or to 100°, there-

fore the net value of the heat utilized efficiently

$$= 13{,}795 + \frac{(13{,}975 \times (190° - 80°))}{190°} =$$

$$13{,}975 + 8715 = 23{,}442.$$

Then the total net efficiency

$$= \frac{24{,}838 \times 100}{40{,}964} = 57 \text{ per cent.}$$

The usual thermic efficiency is therefore satisfactory, allowing for the internal work necessary for combustion and the thermodynamic value absorbed in removing the air from the room. And were economic or cheap fuel gas supplied, there would not be much margin left for improvement

In your last issue your correspondent B. H. Thwaite, C.E., F.C.S., &c., has, I really believe, surpassed himself; for I have not the least idea where to look for such an example of egotistical abuse of science.

Among other things, he talks, as he has done before, about "Carnot's law," whereas, properly speaking, there is no such thing. There is a function known as Carnot's, of which he pointed out the existence, but failed to discover the form thereof, and it has nothing whatever to do with the question at issue.

Neither has the formula $\frac{T_1 - T_2}{T_1}$, which I imagine your correspondent is running

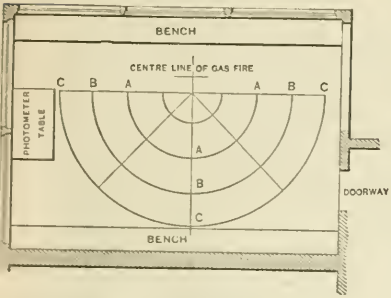

Fig. 1.—Plan of Testing Room.

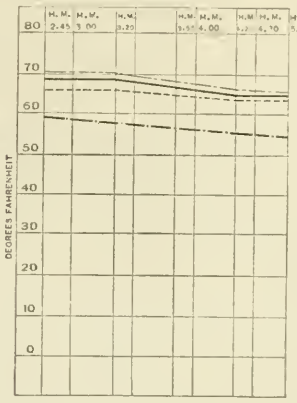

Fig. 2.—Diagram of Vertical Temperatures.

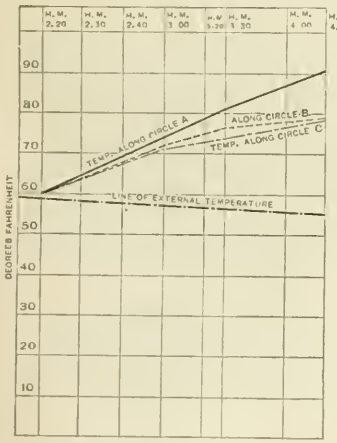

Fig. 3.—Diagram Showing Temperatures on the Semicircles A, B and C in Fig. 1.

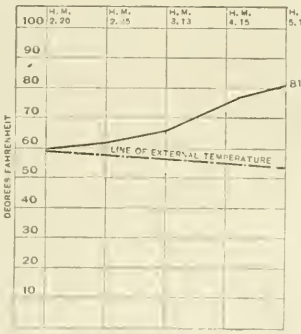

Fig. 4.—Diagram Showing Rise of Temperature Near Ceiling.

But it would take too much of your space to expose all the other evidences of absolute incapacity to deal with his subject on the part of B. H. Thwaite, though there are two which are exceedingly racy, and beat anything that I ever came across in my life, and which is saying a good deal.

Your correspondent tells us that the expenditure of gas was 22 cubic feet per hour for 2 66 hours, whereas there are 2¾ hours between 20 minutes past two and ten minutes past five This does not matter much, however, and I will assume, as correct, that there were 40,964 units of heat expended in so far as gas consumption is concerned.

Mr. Thwaite then says, "We will now approximately determine the distribution of this heat;" and he also notes that "No allowance is made for the human absorption of heat, because the general temperature never exceeded that of blood heat." I should think not indeed, considering that, according to M. Dumas, two average human beings give out, and not absorb, 382 units per hour, or for 2¾ hours 1082 units. Now comes the masterpiece. B. H Thwaite takes the volume of air at 2765.75 cubic feet, multiplies this by 21, the rise in temperature, and by 0.2375, the specific heat of air under constant pressure. The result, as he correctly remarks this time, is 13 785, which he considers as units of heat, totally ignoring the fact that 0.2375 is the decimal of a unit of heat that is required to raise a pound and not a cubic foot of air through 1° F. at constant pressure.

A pound of air at, say, 70° F. and ordinary atmospheric pressure occupies a volume of about 13.3 cubic feet, and, therefore, your correspondent's figure, 13,795, must be divided by 13 3 to give the number of units of heat required to raise the temperature of the 2765 75 cubic feet of air in this room by 21° F. This, in round numbers, is 1004 units, or actually less than that supplied by the respirations and bodies of the two men in the room; so away goes Mr. Thwaite's first efficiency of 33 6 per cent. Without the presence of the men it could only amount to 2 45 per cent.

He makes just the same blunder almost immediately afterward, besides assuming that the volume of the air supplied to the fire is only slightly more than four times that of the gas consumed. This is very absurd; for air to the extent of four times the volume of the gas, we well know, would not even be capable of completely burning it, and an enormous quantity in excess of that required for complete combustion always passes through and over an open fire. Twenty-four times would be much nearer the actual truth, as is evidenced by the low temperature of his products of combustion.

Assuming this, however, and it is all in favor of Mr. Thwaite's great efficiency, we have the fact that 58 52 × 25, or 1463 cubic feet per hour of, practically speaking, air is taken into the room at 59° and discharged into the chimney at a mean of 220°, representing for 2¾ hours 12,190 units of heat expended, while only that portion of it which is employed to heat up the incoming air to the temperature of the room—viz., 1590 units, or about 3.0 per cent. of the total heat of combustion of the gas—can be considered to be useful, and that mainly on the score of ventilation.

So much then for the efficiency of 57 per cent., which dwindles down to a possible 2 45 + 3 9, or 0 35 per cent if no one is in the room. Surely we are not so far gone in these days of science as to fondly imagine that the heating of a room depends upon the heating of the air that was primarily in it and of that which afterward passes through it.

If Mr. Thwaite understood anything at

TEST OF AN OPEN GAS FIRE.

on this kind of gas fire, which, while having the open-glow characteristics so dearly beloved by Englishmen, is essentially scientific and healthy. No part of the stove in contact with the air of the room can become sufficiently hot to cremate the organic suspended matter always present in the atmosphere, and whose contact with ordinary closed gas fires sets up the disagreeable odor of organic cremation.

MR. THWAITE CRITICISED.

In a following issue of our contemporary Anthony J. Bower publishes a letter severely critical of Mr. Thwaite's test, which we reprint below. The letter points out some errors, but is unfortunately personal to an inexcusable degree:

his head against. All that he requires is merely a little schoolboy's arithmetic, without any necessity existing for the consideration of absolute temperatures. The efficiencies of the gas or stove fire, still retaining Mr. Thwaite's erroneous method of putting the matter, would then be 0 932 and 0 875, not 0 8 and 0 905, as he says. But then B. H. Thwaite is far above schoolboy's arithmetic, since a little later on we are told that

$$(13{,}795 + 10{,}505) - 40{,}764 = 16{,}664.$$

I recommend this result as a convenient one for various fraudulent societies, as it might help them out of their difficulties when such have to be seriously encountered.

Again, we have 13,975 + 8715 = 23,442.

all about his subject he would know that nearly all the remaining available heat, or 40,964 — 12,190 = 28,774 units, is expended, firstly, in heating up the walls and windows, and afterward in maintaining a certain desired temperature within the room against the outflow of heat continually taking place through the walls and glass. This it is that constitutes the main useful work of the fire.

I recommend your correspondent to study a practical treatise on heat by Thomas Box before he again inflicts upon us his ideas about heating rooms with open gas fires. Either Mr. Thwaite's arithmetic or carelessness is abominable, and such an exhibition as this last is a disgrace, not only to science, but to Englishmen generally, for foreigners are not slow to take advantage of, and jeer at, such things.

There are many readers of the *Gas World*, and of other scientific papers, who think that some restraint should be placed on this gentleman's gaseous ebullitions, and, to use his own words, there may not have been "the disagreeable odor of organic cremation" round about this gas stove, but there certainly must have existed in the room the very offensive one of cremated common sense.

Strikes in New York State.

The annual report of Labor Commissioner Peck, recently issued, presents an interesting table, showing the number of strikes which occurred in various establishments and industries in the State of New York during the year 1892, with the number of persons involved in them. The information given is the result of a systematic investigation made by the Labor Bureau of the State of New York, and is summarized as follows, each strike representing a separate establishment:

Total number of strikes	1,768
Of these were	
Successful	1,138
Unsuccessful	596
Compromised	28
Pending	6

The total number of persons involved is given as 25,764, or an average of 14.57 individuals to each strike. Final returns are still to be rendered for about 250 minor strikes, in as many establishments, but these will not materially affect the results given as to the number engaged in them and the proportion of successful and unsuccessful.

We extract from the table and present below such information as directly affects the interests represented in *The Metal Worker:*

Trade or industry.	Number of establishments involved in strike.	Number successful.	Number unsuccessful.	Number of persons engaged.
Cement masons' laborers	71	54	17	1,108
Elevator constructors	25	22	3	577
Engineers (stationary)	5	1	4	6
Foundrymen	1	..	1	82
Galvanizers	1	..	1	20
Gas fitters	16	8	8	59
Iron workers (architectural)	8	6	2	285
Iron workers (molders)	1	..	1	35
Machinery constructors	1	1		20
Machinists	3	..	3	47
Pattern makers	1	..	1	8
Plumbers	3	2	1	21
Roofers (slate and metal)	11	9	2	74
Skylight and cornice makers	10	8	2	48
Steam fitters	42	34	8	171
Steam fitters' helpers	42	35	7	199
Tile layers	31	28	3	232
Tile layers' helpers	30	27	3	210
Tin and sheet iron workers	14	7	7	62
Tinware makers	1	1	..	250

Manufacturers' Perplexities.

The Western jobbers and Eastern manufacturers of standard hardware have encountered a difficult problem. The trouble has grown out of the rapid development of important jobbing centers along the upper Mississippi and Missouri rivers and even further West. As long as Chicago and St. Louis houses dominated the West, even serving as depots for the supply of small jobbing houses on the frontier of civilization, there were no conflicting interests to disturb the relations of manufacturers and jobbers. Chicago, of course, resented the ambition of St. Louis in sending traveling salesmen into Northern Illinois, Wisconsin and Minnesota, while St. Louis felt aggrieved when Chicago salesmen were encountered in Southwest Missouri, Arkansas and Texas. Certain territory seemed to belong naturally to the merchants of a particular city. Its invasion by the representatives of a rival city was, however, a matter which concerned only the jobbers and did not involve the manufacturers.

The upper Mississippi and Missouri river jobbers have now become of sufficient consequence to change the situation very materially. They refuse, and have refused for some time, to regard themselves as secondary to Chicago and St. Louis, demanding to be placed on an even footing with the merchants of those cities and claiming territorial rights over trade.

The consequence is that manufacturers have been obliged to concede to their demands and to make prices lower for delivery to these comparatively new jobbing centers than the Chicago or St. Louis price, with freight thence added. In some instances it is known that Omaha, St. Joseph, Kansas City and Sioux City jobbers have secured Chicago or St. Louis prices on their deliveries. They are thus able to sell in competition with Chicago and St. Louis not only further West, as heretofore, but also to the eastward in territory in which their influence had been felt but slightly. It is not surprising that a vigorous protest is uttered by the Chicago and St. Louis merchants against the manufacturers' action in building up still further their young but active competitors.

Manufacturers say that the matter cannot be adjusted in any other way. They are not animated by any spirit of hostility to the jobbing interests of Chicago and St. Louis, but are compelled to recognize the growth of the wholesale trade in what were once known as frontier cities, but are now centers of populous sections. They are obliged to meet new conditions which they have not created, but which they find springing up. On the other hand, they say, if they were to adhere to a rigid policy of billing goods on board factory, with buyers paying freight thence to their own cities, they could be justly charged with refusing to acknowledge the importance of any jobbing center whatever.

Another consideration probably exists for the policy which they have adopted. By making prices for goods delivered in the far West as low or nearly as low as if delivered in Chicago or St. Louis, a strong incentive for the establishment of competing factories is removed. Manufactures are pushing West with sufficient rapidity now and the stimulus of very high prices, if full freight rates from factory were borne by jobber or consumer, would accelerate the movement unpleasantly for those who now have their money invested in such factories. It cannot be disputed that a fixed price to all comers, "f.o.b. factory," would be an ideal arrangement if it could be maintained, as all sections and all jobbing centers would then be placed on an even footing in their own immediate territory. But to complete such an ideal arrangement, a much more ideal condition would be necessary, namely, that there should be no change in the character of manufactured goods, no development of new manufacturing enterprises and particularly no springing up of competing manufacturing enterprises in the West.

A STANDARD PRICE LIST, possessing novel features, has just been issued by Randolph & Clowes of Waterbury, Conn. It embraces their Seamless Drawn Brass and Copper Tubing, Sheet Copper Brass and German Silver, Brazed Tubing, Moldings, &c. To illustrate the general arrangement of the price list, we will take a page of Seamless Drawn Brass and Copper Tubing. This is arranged in seven columns, the first giving the outside diameters, the next three giving "extras over basis price per pound," the "approximate weight per foot No. 8 Stubs' gauge," and the "approximate weight per foot No. 6 B. & S. gauge" for Brass Tubing. The other three columns give the like figures for Copper Tubing. All are printed in black ink, except the two columns giving B. & S. gauges. Pasted in the book at the beginning of this list is the basis price of Brass and Copper, 16 and 19 cents respectively. The figures in the column headed "extras over basis price per pound" are to be added to the basis price. Thus to find the cost per pound of 1 inch Brass Tubing No. 8 Stubs', or No. 6 B. & S. gauge, we add 6 cents to the basis price of 16 cents, getting 22 cents as a result. The main advantage derived from this arrangement is that, should any fluctuation in the market make necessary a change in the basis price, a new basis slip could be sent to customers to take the place of the old one, all the rest of the price list remaining unchanged.

THE THOMPSON MFG. COMPANY, Cleveland, Ohio, issue a notice to the trade that they have opened a New York office at 136 Liberty street under charge of G. M. Maicas, who is the Eastern sales agent. Mr. Maicas has had lengthy experience in this line of business, and is prepared to answer all inquiries. He can furnish an illustrated catalogue of the Thompson Mfg. Company and give prices on corrugated iron and iron and steel roofing, siding, &c. The territory under the direct control of the New York concern includes Eastern New York, New Jersey and the New England States.

The California Legislature has passed a bill appropriating $100,000 for the maintenance of a nautical school at San Francisco. Graduates of the school, it is expected, will obtain positions as junior officers in the merchant marine on the Pacific Coast.

There is no direct trade between the United States and Paraguay, although American merchandise received by way of Montevideo and Buenos Ayres is preferred to European. The consul there says that a sample house should be established in that country where American goods can be displayed and ordered through one large shipping firm.

It is understood that the "City of New York" was recently fitted out with new propellers having three blades each, and great speed was expected as the result of this change. The new propeller's, however, instead of adding to her speed, retarded her almost 3 knots an hour. She arrived in New York last week 15 hours behind her rival, the "Majestic" of the White Star Line.

A statement compiled for the "London and General Freight Report" shows that at the beginning of this month there were laid up in British ports idle steamers to the number of 522, with an aggregate net register of 532,281 tons.

The Relations of Chemistry to Foundry Practice.—II.*

BY CLEMENS JONES, M.E., EASTON, PA.

From this view we have rapidly taken of the chemical elements with which this discussion treats, we are equipped to scan the horizon that now spreads out rather broadly before us, and recognize in approaching objects an intelligent significance of the signals they display, let us hope, in accordance with the codes laid down by the founder's tools and the machinist's lathe. We know pretty well about what objects to expect, and we will proceed in an endeavor to interpret not only the meaning of their appearance, but also to inquire what amounts of each, or all, fulfill the requirements of our search.

Pig Iron.—Pig iron is the raw material out of which the foundryman is required to make a finished casting. What is pig iron? Pig iron is impure cast iron. It is metallic iron combined with nearly all of the metals and metalloids that were contained in the raw ores, the flux, and the combustibles employed in its manufacture. As it comes from the furnace it is unfit for any but the simplest castings. Uncertain in quality and weak, it contains blow holes, is liable to chill and to excessive shrinkage, and is full of foreign fragments floated on its molten surface, as it rises to the top of the mold. This crude iron is in a condition to be cheaply purified and converted into articles most needed in the arts. In the early centuries, before cast iron became in vogue, pure iron was sought as a direct product. The direct process was used until the fifteenth century, and is still extant, notably in China, India and Africa. But these charcoal bloomeries required the finest selected materials, and involved tremendous labor and great expense. Besides, there is no use for chemically pure iron in the arts. On this account its manufacture is not attempted. But iron is combined with other elements, which we regard as impurities, until it has a required hardness, combined with a required strength. The elements employed to effect this change in the physical properties of iron are commonly carbon, silicon, phosphorus and manganese. As we have seen, there are other accidental impurities possible, which may comprise the whole list of elements we have discussed. Nature, provident in this, the greatest need of mankind, disposed of these needful elements in such relation to the deposits of iron ores that crude iron—the alloy with requisite properties—is readily produced, suited to the needs of the artisan. Indeed, so wide is the range in this respect that in earlier days quantity only, without respect to the quality, of the pig iron, was the sole object. Materials were tumbled into the blast furnace without rhyme or reason, and in utter disregard of those self controlling conditions of the process itself which alone were often responsible for a product that was fit for any purpose. Or, on the other hand, the founder's complaints to the furnaceman prevailed in such incessant changes of materials that by an accident of experiments the proper iron was at last made. Without doubt this state of affairs retarded any considerable progress in foundry practice. But blast-furnace practice has undergone a revolution. Chemical knowledge has brought it about. To day the foundryman is in a position to say to the pig-iron makers, "I want such a quality of iron;" and the furnace manager is in a position to light his fires and make it. The pig-iron industry is of such great importance that, independent of economical considerations, he will be obliged to make it. The report of the mineral products of the United States just distributed places the production of pig iron for the year 1891 at nearly 8,300,000 tons, having a value at this city of over $128,000,000. We may, therefore, look confidently to the present day as the dawn of light upon subjects long in darkness. Good workmanship in the foundry requires intelligent methods. These begin with the selection of appropriate materials—those having the right composition. It stands to reason that foundrymen are restricted when they undertake to handle material concerning which they do not possess any chemical knowledge.

While pig iron is usually weak and unreliable, there are instances on record of very strong irons. A good pig iron should stand a breaking strain of at least 15,000 pounds to the square inch. A well-known brand of Pennsylvania iron has an average tensile strength of 17,000 pounds to the square inch. The first remelting of this iron gives a strength of over 22,000 pounds. One test of this brand of iron gave in a gray forge iron the unusual strength of 52,000 pounds to the square inch.

We will not spend much time on the subject of the grades of pig iron. Grading at best is but a local designation. It has the advantage, however, of approximating to the end in view. The grades of pig iron with reference to fracture, may be classed in the following order: Silver gray, brittle, large bright crystals, open grained. 1x, tough open grain free to edges; torn fracture, jagged to the touch. 2x, similar to 1x, but having close-grained spots. 2; even close grained. 3, or gray forge, hard and finely grained. 4, or mottled and white irons. The composition of pig iron, taking the average of the Pennsylvania brand mentioned, for foundry use is about as follows:

	Per Cent.
Carbon, graphitic	3.75
Carbon, combined	0.20
Silicon	2.50
Phosphorus	0.75
Manganese	0.30
Sulphur	0.06
Total	7.29
Iron, &c.	92.71
Total	100

Iron of this composition will answer for general use, will be fluid and make a strong, soft casting. We find from the analysis the amount of each ingredient. Now, in actual practice, we will suppose that this given iron is entirely satisfactory when made into castings for a certain purpose. It melts easily, requiring a modicum of fuel, fills every crevice in the mold, comes out a perfect casting, and can be readily shaped on a lathe. This quality of iron, then, would naturally be sought for similar work. What is there in the appearance of pig iron to indicate its quality? Grading by fracture will not determine quality—that is, composition. Grade alone, judged by the fracture, is of no practical service whatever. Taken in connection with known composition it is of valuable assistance. There are claims held by reputable iron men that the fracture indicates carbon, silicon and every other constituent, presumably to the practiced eye. Still others hold that the face of the pig is an infallible guide for everything. Relied upon by itself there can be nothing more deceptive; the eye, no matter how finely educated, cannot see phosphorus, sulphur, silicon or anything else in an opaque, solid mass. If the blast furnace produced iron at each successive cast of perfectly uniform composition there might be a shadow of validity to such claims, since the free carbon as graphite under regular conditions, is a fairly good indicator. But it has been clearly shown by the best authorities that the two principal ingredients, carbon and silicon, are liable to be affected not only by the temperature of the iron, but the rate of cooling and other physical causes, other conditions being constant. As a matter of fact, not only do graphite and silicon vary in different casts, when using the same mixture of ores, &c., but there is even marked variation between the pigs in the different beds. It is asserted on good grounds that graphite is an index of silicon, for the reason that in certain amounts it changes the combined carbon to graphite—that is, precipitates it. But what visible means is there of determining exact amounts of silicon? There are many recorded cases of rich open grained irons that in reality contained hardly enough silicon to make the melted iron pour without clogging. Analysis from this array of facts is the only true guide. In these connections the relations of chemistry to foundry practice cannot be misapplied. Here a practical illustration may be of service. Pig iron is introduced into a cupola, fuel is added, flux is added to take up the excessive impurities, a current of air is blown in to increase the heat. The pig iron was smelted from its ores—chemical forces operated to produce it. The fuel, as we have seen, is a form of carbon—a chemical substance. Lime is the base of the flux employed; it unites with the acid impurities to form a liquid purifying bath—by chemical reactions. Oxygen, the tireless vital principle of the air, causes the combustion of the fuel with generation of intense heat—a type of chemical energy. The molten fluid metal, sparkling in the ladle, fills every crevice of the mold, and is at last uncovered from the steaming sand—a chemical product.

Cast iron is that kind of iron which neither tempers nor welds. This is rather a distinction than a definition. It compares with steel, which is that kind of iron capable of assuming temper, and with wrought iron, which may be welded, but will not take temper by chilling. There are, however, qualities of steel which may be welded, bent, and do not take temper. But to a certain extent these distinctions are caused by the behavior of carbon, and at the same time the absence of certain other elements. White iron becomes steel when its carbon is reduced to about 1.5 per cent., at which point it has slight weldability and great hardness. We may say that cast iron is a compound with varying quantities of carbon and silicon. Steel may contain silicon, but has less carbon than is needed to form cast iron. Wrought iron is nearly pure.

Let us now briefly examine the influence of the chemical elements with which we have become acquainted upon the quality of cast iron. When pig iron is melted in a cupola we look for a slight change of composition in the resulting cast iron, owing to oxidation caused by the blast of air. The tendency of this effect is to lessen the amounts of the more readily oxidizable elements, such as manganese and sulphur. Silicon and combined carbon afford combustible material to oxygen, and these elements are burned and also reduced in quantity. The practical effect, when a mixture contains the right proportion of carbon, silicon, phosphorus and manganese, is a uniform iron, in which, so to speak, the carbon as graphite is finely subdivided. This state of subdivision, in which all the carbon is still graphite, increases the tenacity between the particles of surrounding metal by placing them in closer contact and imparts a texture resulting in greater strength. By the same process, it is well known that up to a certain point subsequent remeltings give greater strength to cast iron, which from the first melting may be even doubled. We do not know accurately whether in addition to this the alloy may not be said to

* An address before the Foundrymen's Association of Philadelphia.

be intensified and a firmer grasp upon each other given to the combining elements. But the texture is improved by a rearrangement in molecular structure, and the actual composition may not have varied to any considerable extent. Illustrative of the effect of melting on pig iron, the following analysis, quoted by one of the greatest authorities on the subject of iron, will be instructive in several ways. The iron was graded as No. 1 pig. On remelting, it turned hard and white. The analysis of the original pig, and as remelted for castings, was as follows:

	Pig.	Castings.
Carbon	1.61	1.65
Silicon	0.98	0.61
Phosphorus	1.37	1.95
Sulphur	0.16	0.29
Manganese	0.12	0.47
Calcium	0.40	0.81
Magnesium	0.29	0.43
Total	4.93	5.51
Iron	95.15	94.42
Total	100.08	99.93

Observe that phosphorus and silicon sustained a loss, but the carbon remained practically the same, and sulphur and manganese increased, as well as the other two ingredients. Now, the phosphorus and silicon were oxidized, but the carbon was in all probability entirely graphitic. The gain in sulphur and manganese was undoubtedly due to bad fuel—a frequent source of trouble to the foundryman. Previous analysis of this particular pig iron would have avoided all difficulty. A critical study shows that it was deficient in carbon—should have contained twice as much. With the low silicon—of which the same holds good—this iron would have turned white, supposing that sulphur and phosphorus were not excessive. The abnormally high phosphorus and sulphur only increased the hardness of the metal. The gain in manganese is unusual, and had reached a point where, with the other constituents normal, chilling is so often sure to follow. Of calcium and magnesium, aside from the correctness of the analysis, the effects need not concern the result. But it is highly probable that had carbon and silicon been normally high, the increase in these elements, as well as sulphur and manganese, would have been prevented. Now, the analysis would have shown the deficiencies in this iron. With a knowledge of the chemical effects of these elements on cast iron, no foundryman would have attempted to melt this iron alone. It is important to understand clearly the fact that these chemical effects produce physical properties. The remedy is simple. The analysis points it out. A mixture of this iron with another iron containing more carbon and silicon and less phosphorus and sulphur, so as to result in a composition corresponding to that of the Pennsylvania iron, would have made soft, strong castings. Hence the practical application of chemical analysis to the materials used in the foundry is apparent.

The quantities of the chemical elements in cast iron giving the best physical and economic results have been fairly well established. They may be considered in their relation to cast iron as hardeners and softeners. Carbon is a hardener. In pig iron carbon rarely exists over 5 per cent. Metallic iron is capable of combining with even 7 per cent. as a maximum. Beyond this amount it separates outas graphite, of which "kish" is an example. But part of the carbon is replaced by the other elements, as already pointed out. As a consequence it rarely exceeds 4 per cent. In the condition of graphite the range in cast iron is from 3 5 to 4 per cent., in which amounts it imparts the greatest strength, for which purpose it is necessary. Carbon makes iron work hot and gives it fluidity. It makes it soft and easily cut by a tool. Silicon is the regulator of carbon in cast iron. Cast iron comparatively free from other elements and high in combined carbon is white, crystalline, hard, brittle and may be specular. Silicon appears to change the combined carbon to graphite and produces gray iron. It therefore adjusts carbon to make cast iron hard and strong or soft and tough. The range of silicon is wider than that of carbon. Over 3 per cent. of silicon gives hardness to cast iron and increases shrinkage. At 2.5 per cent it gives maximum fluidity to cast iron, which can be used for the thinnest castings. But if a large casting, to be subjected to tensile strength or to resist a great crushing weight, the amount of silicon should be less. Silicon thus plays the part of both hardener and softener. Cast iron is soft and easily worked, containing from 2 to 2.5 per cent. of silicon. For common castings, such as pipe, &c., even 1.75 gives good results. Phosphorus should always be well controlled. With proper adjustment of the other ingredients it makes iron hard and causes excessive shrinkage. Some authorities consider 0.50 per cent. all that is necessary, but more than this amount may be safely employed. The range, however, is more limited, and, except where very fluid iron is required, should not exceed 0.80 per cent. High phosphorus sometimes results in hard spots in castings. Manganese makes iron brittle and increases shrinkage, chilling and hardness. It weakens iron and reduces its ability to stand stress. On this account more than 0.40 per cent. is undesirable in ordinary cast iron It is a useful ingredient in making chilled castings, such as rolls, &c. Above 1 per cent. the hardening properties are lessened. Sulphur is one of the ingredients whose presence is not sought. It is a great hardener, and appears to increase combined carbon, which, as seen, is inimical to soft iron. It is always injurious to iron. In wrought iron sulphur causes brittleness at a red heat, and makes it "red short." This property is opposed to the influence of phosphorus, which makes it "cold short" at ordinary temperatures. But these terms do not properly apply to cast iron, although there is an old foundry saying, that a neutral iron may be made by combining red and cold short iron. Aluminum exists in such small proportions in cast iron that its influence is not often felt, but it appears to impart strength and elasticity. Introduced into melted iron, it is considered to act beneficially by collecting scum and slag, and produces sounder castings free from blowholes. Arsenic acts very much like sulphur on cast iron and is as greatly to be avoided, although but seldom encountered. There is no evidence to show that titanium injures cast iron, perhaps one reason being that it occurs in only small quantities. Copper is a hardener of iron, and in appreciable amounts weakens it. The other rarer elements, nickel, chromium, tungsten, &c., are so rarely to be found that their effects on cast iron are not accurately understood. They have been more used in connection with steel, the strength of which they appear rather to increase than diminish. But their occurrence in pig iron, and our knowledge of the fact, will pave the way to any future enlightenment concerning the effects they may produce. Cast iron, with the properties generally required, we may consider to be of a composition of from 3 to 4 per cent. carbon; 1 75 to 2.75 per cent. silicon; 0.25 to 0.85 per cent. phosphorus; 0.15 to 0.35 per cent. manganese, with as few other impurities as possible. The final point in our discussion is, as to whether it is better to depend on chemical analysis or upon practice in making iron castings. There will be no dissent from the opinion that they must and will go hand in hand. Since we can govern the amounts of the ingredients of cast iron, any desired property may be given to castings of which it is composed.

There is no law as yet resulting from the commerce between the laboratory and the foundry. Without doubt, there is too much to learn that prevents the formation of simple, definite rules applicable to modern foundry practice. But these will come in time as the relations of chemistry to foundry practice become better and more generally understood. There are a thousand minds at work on the problems of science—chemists thinking in every language of the civilized globe of the subjects we have here discussed. Science improves every industrial condition to which it is applied. It is not possible, with accumulating facts rising to activity, that even in so humble a factory as the iron foundry they may not find practical application from day to day.

Ocean steam navigation as concerns the United States is passing through a new stage of development. There is a louder call than ever for increased service, particularly in the coastwise trade on both sides of the continent, and railroad corporations are more than ever inclined to have a transatlantic service under their own control. Unfortunately, the new tonnage called for will be largely the product of foreign yards. First in prospect are the new ships of the Inman line, to be of American build. Then there are the new freight steamers for the Chesapeake & Ohio Railroad, to be built on the Clyde, at once. And besides a proposed line between Philadelphia and Jacksonville, Fla., for fruit transportation, the Trades League of that city are making an earnest effort to establish a first-class line to Havana, Mexico and other Southern points. From San Diego, Cal., word comes that a through line is just going into operation between that port and Mazatlan, in Mexico. Of deeper significance is the rivalry taking place to secure control of the California trade by water routes, as the clipper lines seem destined to contend with a stronger opposition growing out of the disruption of the old joint arrangement between the Panama Railroad and Pacific Mail Steamship companies. The latest scheme is to start a line of English built steamers from New York around Cape Horn to Chili and Peru. The pioneer steamer, "Coya," from Swansea, to sail in a few days, will be followed, it is stated, by vessels which have been contracted for in English yards at a cost one-third less than it could have been five or six years ago. As an experiment this long-voyage business, covering about 8000 miles, will be interesting.

A light, cheap and ornamental shelf, adapted to be attached to a stove pipe, forms the subject of a patent recently granted to Edward A. Loebs of Rochester, N. Y. The shelf is indented at its edges to meet the pipe, and has downturned tines and brace rods in combination with the frame to hold the shelf. The shelf may be readily detached from the frame or holder upon which it rests when desired. The construction is such that the frame or holder may be directly attached to the stove pipe.

The Pacific Mail Steamship Company decline to receive freight at San Francisco for New York via the Isthmus.

Never but once before since the white man settled the country was the Mississippi frozen from shore to shore and an ice gorge formed at Memphis.

At Springfield, Mass., the National Needle Company make and finish every year 30,000,000 machine needles.

TRADE REPORT.

The Iron Market.

There have been no features developed in the market of especial interest during the past week, and while no advance is noticed in values, prices of a week ago very generally represent the market. The feeling seems to be gaining ground that higher prices are not to be expected in the near future, and that outside of standard brands of Pig Iron at least, orders will continue to be for small quantities. The outlook for business is fairly satisfactory and a good demand is anticipated, though orders may cover immediate requirements rather than future deliveries. In the West the recurrence of severe winter weather the past week has caused another congested period in the operations of railroads, and merchants report more trouble than ever before with the prompt transmission or receipt of freight. This difficulty is becoming more serious, especially as the best-managed and best-equipped roads appear to be unable to improve the situation. There is a scarcity of both cars and motive power, which is becoming more pronounced every week.

In the New York market trade is quiet, generally speaking, with a somewhat easier market. The Thomas Iron Company are booking orders from their old customers for delivery during the balance of the year at last year's prices, although the figures for the current year have not been officially announced. New York quotations are as follows: Northern brands, $14.75 @ $15 25 for No. 1; $14 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14 75 @ $15 for No. 1; $13 75 @ $14 for No. 2 and No. 1 Soft; $13.25 @ $13 50 for No. 2 Soft.

The situation of Pig Iron in the Philadelphia market could almost be defined in the single word "unchanged," but even that will bear some little qualification. Prices are certainly unchanged, but it is open to doubt whether the feeling is as steady as it was a week ago. With some sellers it may be a little firmer, with others there is more nervousness and perhaps more of a desire to get out at some price. The best brands are handled without the slightest necessity for shading, but with others the supply is so liberal that buyers require coaxing, and when a sale can be made at last week's figures holders are quick to accept. The local trade appear to have covered pretty freely within the past 30 days, and while there is no extraordinary pressure to realize there is also an absence of demand, except for the general run of trade, which is chiefly for small and medium sized lots of standard qualities. The feeling in regard to the future seems to be that prices are not likely to be higher, and as there is a possibility of somewhat cheaper ores consumers require special inducements before they will negotiate for large lots. Producers are not in a position to anticipate lower figures, any more than consumers are under the necessity of discounting their future requirements. For Philadelphia and near-by deliveries quotations are as follows:

American Scotch, No. 1X.....	$17.00 @ $17.25
American Scotch, No. 2X.....	16.00 @ 16.25

In the West an excellent business is reported for the past week in local Coke. The volume was, perhaps, not so large as that of the previous week, but was deemed quite satisfactory by the furnace companies. Negotiations are pending for additional quantities, so that the end of the season of activity is not yet visible. A retrospect of the trade of the past two months is rather encouraging to the makers. They started in January with a weak market, which looked as if there would be a very considerable decline in order to meet the views of buyers. The large transactions which have since taken place on a much better basis than feared have checked the tendency to very low prices, and it now looks as if there would be no further decline, unless very unfavorable conditions should arise.

At Chicago, sales of Southern Coke are reported of larger size than for some time. These sales were effected by concessions on the part of small Southern companies having an accumulation of Soft Iron which they were anxious to move. The transactions are believed by the sellers themselves to be exceptional, and not to fully represent the market. The prices made were but little above the level of those of last September. Lake Superior Charcoal has been considerably less active than Coke Iron, but consumers are known to be in early need of renewing old contracts, and considerable business is therefore expected in the near future. Makers of this class of Iron are feeling increased confidence in the prospects for this year, and some of the most discouraged among them are now making predictions of higher prices, which are rather sweeping in view of the general condition of trade. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal.....	$16.50 @ $17.00
Local Coke Foundry, No. 1.....	13 25 @ 13.75
Local Coke Foundry, No. 2.....	12 75 @ 13.25
Local Coke Foundry, No. 3.....	12.50 @ 12 75

In Southern markets there is nothing new to report of the Pig Iron market, there being a light volume of business, and the existing demand is fully supplied at quotations of a week ago. The current consumptive orders have been even smaller than the preceding week, and as there is no large buying for forward delivery the aspect is anything but encouraging, though prices seem to be down to rock bottom, and there appears to be no disposition on the part of the furnaces to stimulate trade by offering to make further concessions. Doubtless the new departure recently made by the Northern furnaces to meet all competition has turned much consumption into new channels, but there are evidences that consumption is large for nearly every purpose, and if the demand is comparatively light for forward delivery it must be made up by increased buying for current consumption before long. Quotations are unchanged, as follows:

Foundry.

Southern Coke, No. 1.....	$13 25 @ $13.50
Southern Coke, No. 2.....	12.00 @ 12.25
Southern Coke, No. 3.	11.50 @ 11.75
Ohio Soft Stone Coal, No. 1.....	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2	15.00 @ 15.25
Mahoning and Shenango Valley...	15 25 @ 16.25
Hanging Rock Charcoal, No. 1....	18 00 @ 19.25
Hanging Rock Charcoal, No. 2....	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1...	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2.....	14.50 @ 14.75

Billets and Rods.—The market has been particularly quiet, both in foreign and in domestic material. We quote Steel Billets, tidewater, $24.50 @ $24 75; foreign, $29 @ $29.50; Wire Rods, $32.25 @ $32.75; foreign Wire Rods, $40 @ $40.50, and Swedish Rods, $54.50 @ $56.

Steel Rails.—The only transaction referred to by any Eastern mills is the sale of about 3000 tons to a Southern road at private terms. At the present time there is very little business in sight, and it is not likely that any marked activity will prevail. From the West come reports that considerably more business has been placed than is generally known, and that as a matter of fact the works have larger orders on hand now than they had at the corresponding period last year.

Metal Market.

Copper.—The market has remained quiet, and there is no sign of change in any particular. Small spot lots offered at prices as low as any that have been quoted thus far this month seem to virtually go a begging, and the presumption is that if consumers are as busy as they are represented to be, and using up large quantities of Ingot, they must either have a good stock of material on hand or be quietly supplied by some private arrangement with leading producers.

Pig Tin.—The situation is wholly unchanged. Values have fluctuated within

very narrow bounds, speculation has been confined almost wholly to a limited circle and the movement of Tin into the channels of consumption has proceeded in about regulation manner. Apparently the tendency is to keep an even keel until some word comes from Washington as to the probability of an extra session of Congress, and if one is called, receipt of information as to what may be done in the direction of repealing the duty prescribed in the McKinley Tariff act.

Pig Lead.—There has been only a moderate business and the status of the market is practically the same as it was a week ago, with buyers and sellers evidently inclined to follow a conservative policy for the time being.

Spelter.—No change for the better is visible in the market for Western brands.

Antimony.—The market has remained quiet and unchanged.

Tin Plate.—Fairly large sales have been made of 100 lb and lighter Bessemer, Coke finish Plates for May and more distant future shipment. The prices, it is understood, were very close to those quoted for spot stock. Otherwise business has continued quiet and hardly any change in values has taken place.

Coal.

The Coal trade is not disturbed by the sudden rupture and collapse of the Reading "combine" under the ambitious management of President McLeod. One of the Coal company presidents remarks that a natural effect will be to deaden trade for the moment, as consumers will be on the lookout for a drop in prices, especially as the spring season is approaching, when a drop is expected from natural causes. At present there is a plenty of Coal, the small Steam sizes being in better supply. The best grades of the latter may be quoted: Pea, $3, alongside; Buckwheat, $2.20, alongside. The common understanding of the situation is this: That the inevitable has happened to the "combine" launched one year ago with much trumpeting; only the dissolution now chronicled occurs sooner than was anticipated. The scheme to absorb all New England via the Poughkeepsie Bridge was impracticable. Thereupon, reaching out for one railroad after another, with credit already strained to the utmost, invited a catastrophe. But radical changes in the Coal business are not looked for, as Mr. Wilbur of the Lehigh, who is associated with Mr. McLeod in the receivership, also Mr. Paxton, are recognized as conservative, but operations will be conducted on a comparatively limited scale.

Shipments of Anthracite Coal for month of January, 1893, compared with the corresponding period last year:

Wyoming region	1,875,094	Inc. 354,166
Lehigh region	407,794	Inc. 11,402
Schuylkill region	786,690	Dec. 147,476
Total.	3,069,579	Inc. 218,092

The stock of Coal on hand at tidewater shipping points January 31, 1893, was 532,375 tons; on December 31, 1892, 657,868 tons; decrease, 125,493 tons.

The first shipment of Coal by the Lytle Coal Company from their new colliery at Primrose, near Minersville, has been made, and when fully in operation the colliery will be one of the largest producers of the region.

Bituminous Coal is unchanged. A contract has been made for the delivery at London, England, of 40,000 tons of Cannel Coal from the Jellico district, Southern Kentucky. It will be shipped via the Chesapeake & Ohio from Norfolk.

The Dominion Coal Company, Limited, who have secured control of the Cape Breton Coal mines for the next 100 years, have organized with the following officers: President, Henry M. Whitney, Boston; treasurer, John S. McLennon, Montreal; secretary, B. F. Pearson, Halifax, N. S.; chief engineer and general manager, F. S. Pearson, Boston; resident manager in Nova Scotia, David McKeen, Cape Breton.

Financial.

Outside of speculative circles the markets are undisturbed. Business is in good volume, and, irrespective of currency questions, general conditions are favorable to an active spring trade. In Wall street uneasiness is felt on account of the low stock of gold in the Government Treasury, and many express disappointment that Secretary Foster should hesitate to issue gold bonds as a measure of temporary relief. The Senate on Saturday evening passed an amendment to the Sundry Civil bill authorizing the Treasury to issue five-year 3 % bonds. Pending further action gold shipments are undiminished, and it does not yet appear that local bankers are disposed to co-operate on the line recently marked out in tiding over any temporary difficulty. It also remains to be seen whether the House will pass Mr. Sherman's amendment, or whether the authority intended to be conferred will be exercised either by the present Treasurer or his successor. Again, from what source are additional supplies of gold to be derived? And why should gold be borrowed for the purchase of silver rather than suspend the monthly purchases? Certain it is that, whatever the cause, the drain of gold continues and that the issues of paper therefor, virtually redeemable in gold, only aggravate the difficulty.

The subject next in importance bearing upon questions of finance is the supposed collapse of the Reading "combine," resulting in enormous sales of Reading stock, equal to something like one-half of the entire transactions on the Stock Exchange during the week. The trouble is supposed to have originated in the lease of the Lehigh Valley and New Jersey railroads a year ago, with the object of controlling the trade in coal. In consequence of this expansion the Reading management, as reported, was compelled to resort to a loan for the payment of its annual interest, hypothecating valuable assets for this purpose.

Banks, trust companies and other corporations loaned on real estate in New York and Brooklyn last year $68,000,000.

Chicago Report.

Scrap.—Prices are weak under large offerings. Rubber is an exception, being dearer. Dealers quote the following buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12.00	....
Old Gas-Pipe and Boiler Tubes	9.00	....
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	13.00	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—Very active business is reported, with the continuance of severe winter weather, but quotations remain as follows on carload lots of 12 net tons:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

The production of cypress lumber in Louisiana and Arkansas is becoming important. In Delaware cypress logs are obtained by probing with a long pole in the swamps.

John Huntington of Cleveland has bequeathed $700,000 to be used in building an art and polytechnic school in that city, and a further sum of $800,000 as an endowment fund for it.

A treaty has been formulated for the annexation of Hawaii to the United States, and for the purposes of government extending to that country the laws now in force in Alaska. The royal family are to be pensioned and the indebtedness incurred by Hawaii in England shall be assumed by the United States, compensation therefor to be obtained by appropriating the revenues of the islands, said to be about $10,000,000 per annum.

Mr. Giffen, the English statistician, has given some recently compiled figures of the cost of strikes in Great Britain before the English labor commission. During the years 1890 and 1891 he estimates that a sum of nearly $13,000,000 was lost to wage earners in England by strikes, without bringing into the reckoning the loss caused by the consequent diversion of trade into different channels.

CONDITION OF THE

Hardware Trade.

THE PAST WEEK has made little change in the general situation, there being, however, something of an improvement in the volume of business. Travelers are busily engaged in their different fields, and the result of their activity is the obtaining of many orders, which are keeping jobbers and manufacturers fairly busy. Notwithstanding the fact that the market is devoid of special strength, and is characterized in a good many lines by more or less weakness, the trade are purchasing for their early requirements, the general impression being that prices on the whole are not likely to settle much lower. It is also recognized that some goods are abnormally low, with a possibility of recovery at any time. Business has to some extent been interfered with by prevalent storms and the backwardness of the season, but the tone of the trade is confident, and it is expected that the season's business will be large.

Advices from Chicago. — The Shelf Hardware trade is considerably better in this locality than up to the same time last year. Trade, however, has been light from Northern Michigan, Wisconsin, Minnesota and North Dakota, on account of the heavy snows, which have interfered with almost all traffic in that part of the country. This has checked the Hardware trade at Milwaukee and other points in the Northwest, from which complaints are heard of decided dullness. Other sections of the West are buying more plentifully, so that the average trade of Chicago jobbers is now ahead of last year, as stated. The movement consists principally of straight Hardware and seasonable goods, but a little better inquiry is reported for staple articles. The demand for the latter is not for immediate shipment, but generally for future delivery. Buyers think that it is now a good time to place their orders at prices probably as low, if not lower, than they will be next month. Heavy Hardware jobbers report matters rather quiet in their line, although some are in receipt of special business which keeps them fairly active. Their customers, such as wagon makers, carriage makers and other manufacturing establishments, anticipate a very heavy year, but are not buying just now, being inclined to wait until spring opens, and the crop question is a little better determined.

Notes on Prices.

Cut Nails.—It is difficult to report accurately the ruling prices for Cut Nails, in view of the uncertainty which for the past two weeks has characterized the market in regard to the basis for transactions. At a meeting held in Pittsburgh on the 15th inst. the Nail manufacturers, principally from the West, took action which was somewhat of a surprise to the trade at large, although those who were best informed in regard to the matter knew that it was under contemplation. At this meeting the Wire Nail card was adopted as the basis for Cut Nails, disposing at once of the National Price-List adopted two weeks before, and the regular Cut Nail card which has been in use for some time. In addition to the adoption of the Wire Nail card it was agreed that no sales or quotations should be made on any system of average. The mills pledged themselves to sell simply at a base price without regard to extras. This was regarded as an essential part of the action, as the manufacturers are very desirous of doing away with the system of averages, which in their judgment is detrimental to their interests as well as very inconvenient to the trade. The above action was unexpected by the Eastern manufacturers, and there has been some difference of opinion as to their course in view of it. A meeting was held in Philadelphia on Tuesday, in which the matter received careful consideration, and as a result the action of the meeting at Pittsburgh was ratified with some slight modifications in the card to adapt it more fully to Cut Nails. By this action substantially the same card is to serve for both Cut and Wire Nails. It was also decided by this meeting at Philadelphia that the base price for large lots should be $1.40, on dock, New York. It is as yet, however, too early to give a definite quotation on the new basis. During the past week there has been a good deal of confusion in basis for quotations, each manufacturer using his own judgment in the matter. On the whole, the tone of the market is not different from what it has been. It remains to be seen what effect the adoption of the Wire Nail card will give to prices.

Advices from Chicago.—The new Cut Nail card was adopted at once by the trade here, both by the manufacturers and merchants. General satisfaction is expressed at the action of the Cut Nail Association in adopting the Wire Nail card, as there will be now no necessity of comparing two cards and doing a great deal of figuring to determine which offers the most inducements. The Cut Nail and the Wire Nail will be compared from this time on precisely the same basis of cost. Manufacturers report many inquiries, but buyers are slow to place their orders. It will probably take a little time for the trade in general to adjust themselves to the new conditions. The price on factory lots made here is now $1.42½, Chicago, with no regard to average. The merchants have adopted the price of $1.50 from stock on the new card on any quantity.

Wire Nails.—The Wire Nail market continues in excellent condition, the lowest quotation being $1.40 for carloads, f.o.b. Pittsburgh, an advance of 2½ cents being made for Nails at Cleveland or Salem. Small lots from store in New York are held at $1.75, and carload lots at $1.65. The agreement among the manufacturers is promising well for the stability of prices.

Advices from Chicago.—Manufacturers of Wire Nails report orders coming in at the higher prices. These orders are frequently accompanied by specifications showing that the Nails are wanted immediately. The outlook is decidedly better, and every indication exists that the quoted price of $1.57½, Chicago, from factory, is being strictly maintained. Merchants quote $1.60 for carloads for mixed cars and $1.65 for small lots from stock. They observe remarkable fluctuations in the demand, according to the weather. Whenever a break of two or three days occurs in the rigorous weather the demand immediately springs up in considerable proportions, but the recurrence of winter weather causes it to shrink as rapidly.

Barb Wire.—The Barb Wire market is in good condition and competition is less active than some time ago. Trade is fair, though not specially heavy, but we are advised that stocks are not accumulating. Some of the manufacturers are making efforts to secure better prices, and the market, on the whole, is somewhat stronger. Quotations remain, however, without important change.

Advices from Chicago.—Manufacturers state that orders are now liberal, with an increasing volume of business from week to week. Reports from their salesmen indicate that as soon as spring weather makes its appearance the demand will be very heavy. They continue to quote on the basis of $2.20 and $2.60 for Painted and Galvanized, from factory, with 10 cents advance on less than carloads. The extremely low prices made by some of the Northwestern jobbers have been withdrawn, but there are still some who are quoting Galvanized on the basis of $2.60 to $2.65, for immediate shipment.

Tackle Blocks.—The Tackle Block market continues in an unsatisfactory condition. The termination of the agreement between the different manufacturers leaves them free to make such prices as they choose, and the result has been considerably lower quotations. A discount of 70 and 5 per cent. is thus made on ordinary lots, and a discount of 70 and. 10 per cent. on larger orders.

Standard Fiberware.—The Standard Fiberware Company, Mankato, Minn., have recently announced reduced prices on their line of Flax Fiberware. No. 1, or plain, is made assorted colors, maroon, brown and gray ; No. 5, or decorated, is made assorted, red, blue, black, brown, maroon, old gold and green, selected, with hand-painted decorations and with extra finish or striping as suits the article ; No. 5X, or white, is similar to No. 5 except color. The company's revised price-list is as follows :

	Price per dozen. No. 1	No. 5	No. 5X
Water Pails, 12-quart	$3.00	$4.00	$4.75
Dairy " (yellow), 14-quart No. 3, $4.00	....	4.50	....
Fire Pails, No. 1, $4 ; No. 2, 14-quart, $4.50.			
Sugar Pails (with cover)	5.50	6.00	....
Horse " (short, wide and heavy)	4.50	....	....
Buggy Pails (short and light)	3.50	....	....
Prison " (with cover)	7.50	....	....
Slop Jars (bal. trap), No. 5 and 5X, 14-quart	7.50	8.50	9.50
Chamber Pails, Slop Pails, Commode Pails, Nos. 5 and 5X, 14-quart	6.00	7.00	8.00
Commode Rings	1.50	1.75	2.00

Wash Basins, 10½-inch	1.80	2.00	2.50
" 12-inch	2.00	2.50	3.00
" 13½-inch	2.50	3.00	3.50
" 15 inch	3.00	3.50	4.00
Wash Bowls	....	3.75	4.25
Pitchers	....	5.25	5.75
Milk Pans (Old Gold, in No. 5)	....	2.25	2.75
Fruit Bowls	....	2.00	2.25
Keelers, 11½-inch	....	3.50	4.00
Waste Paper Baskets, 13 inches high	....	5.50	6.00
Mats, 8½-inch (for table use)	1.00	1.25	1.50
" 15 inch (for cuspidors, &c.)	3.00	3.50	4.00
" 17-inch (for slop jars, spittoons &c.)	3.50	4.00	4.50
" 2 -inch (for slop jars, spittoons, &c)	4.00	4.50	5.00
Cuspidors, 8½-inch by 7¼ inches high	....	7.50	8.50
Spittoons, " Daisy," 8-inch (pressed)	3.50	4.00	4.50
Spittoons, 10 and 11½-inch	5.50	6.00	6.50
Peck Measures	3.50	....	....
Half-Peck Measures	3.00	....	....

The Lee Filter Joint —The following is the price-list of the Lee Filter Joint, manufactured by Thomas Lee, 79 and 81 Race street, Cincinnati, Ohio. It is subject to a discount of 33⅓ per cent.:

	Per dozen.
3 inches, IX Tin	$18.00
4 inches IX Tin	20.00
5 inches, IX Tin	24.00
6 inches, IX Tin	28.00
2½ inches, Galvanized Sheet Steel	18.50
3 inches, Galvanized Sheet Steel	20.50
4 inches, Galvanized Sheet Steel	22.50
5 inches, Galvanized Sheet Steel	25 00
6 inches, Galvanized Sheet Steel	27.50

American Roofing Plates —James B. Scott & Co., 122 and 124 Second avenue, Pittsburgh, Pa., quote New York prices on their American Roofing Plates as follows:

Scott's Terne, all Stamped.

Scott's Extra Coated, resquared, IC, 14 x 20	$9.25
Scott's Extra Coated, resquared, IX, 14 x 20	10.75
Scott's Extra Coated, resquared, IC, 20 x 28	18.50
Scott's Extra Coated, resquared, IX, 20 x 28	21.50
Neville, IC, 14 x 20	6.00
Neville, IX, 14 x 20	7.25
Neville, IC, 20 x 28	12.00
Neville, IX, 20 x 28	14.50

Prices at Chicago are 25 cents advance on 14 x 20, and 50 cents advance on 20 x 28 sizes, over prices in New York.

W. P. Loughry, 81 John street, New York, representing the Glendale Tin Plate Company, quotes prices on their Terne Plates in New York as follows:

Optimus Best Redipped	IC, 14 x 20	$8.25
Optimus Best Redipped	IC, 20 x 28	16.50
Optimus Best Redipped	IX, 14 x 20	9.75
Optimus Best Repipped	IX, 20 x 28	19.50
N. F. Old Style Redipped	IC, 14 x 20	7.50
N. F. Old Style Redipped	IC, 20 x 28	15.00
N. F. Old Style Redipped	IX, 14 x 20	9.00
N. F. Old Style Redipped	IX, 20 x 28	18.00
Bonus Extra Coated Roofing	IC, 14 x 20	6.75
Bonus Extra Coated Roofing	IC, 20 x 28	13.50
Bonus Extra Coated Roofing	IX, 14 x 20	8.25
Bonus Extra Coated Roofing	IX, 20 x 28	16.50

H. R. De Milt & Co., 238 Water street, New York, quote the following prices on their American Roofing Plates at New York:

De Milt's First New York	IC, 14 x 20	$5 75
De Milt's First New York	IC, 20 x 28	11.50
De Milt's First New Jersey	IC, 14 x 20	5 75
De Milt's First New Jersey	IC, 20 x 28	11.50
De Milt's Manhattan	IC, 14 x 20	7 25
De Milt's Manhattan	IC, 20 x 28	14.50

Augers and Bits —The market for Augers and Bits, which has been fairly steady for some time, has recently shown signs of weakness and slightly lower prices are made by some of the manufacturers.

Rosin.—Another advance has taken place in the price of Rosin. The market is represented by the following quotations (₱ 280 lb), which are announced by F. W. Blossom, 124 Water street New York:

	In store.
A, black	$ .50
B, common	1.51
C, strained	1.52
D, good strained	1.54
E, No 2	1.55
F, good No. 2	1.65
G, low No. 1	1.75
H, No. 1	2.15
I, good No. 1	2.55
K, low pale	3.20
M, pale	3.85
N, extra pale	4.05
WG, window glass	4.30
WW, water white	4.60

Glass —The condition of the weather during the past week has necessitated a stop of all building operations, so there is no demand for immediate delivery of Glass. The new prices of the National Window-Glass Company have gone into operation, and early enough in the year for dealers to figure with certainty upon the cost of American Glass during the coming year. Those interested in the new company express themselves satisfied that the organization will prove a success, and that it will not conflict with any of the anti trust laws. It is understood that manufacturers are permitted to sell their product to jobbers who are members of the National Window Glass Company at any price agreed upon between the manufacturer and jobber, but that no Glass is to be sold to others than members of the company for less than schedule prices. This is certainly an inducement for jobbers to become members of the company, as it will pay them a good profit if they can buy Glass, say at 85 per cent. discount and sell it at 80 and 5 per cent. discount, besides putting them on an equal footing with others to obtain the best price they can in an open market. No official announcement has been made of the plans under consideration in forming the Imported Window Glass Association in this city, but it is reported that members will be under bonds not to transgress any rule made by a central committee, and that prices shall be on a sliding scale based upon quantities. The prices on imported Window Glass show no improvement up to the present time, sales being made from 80 per cent. discount to 80 and 5 per cent. discount. From reports it appears that the Plate Glass general agency plan has already stopped the ruinous cutting of prices, which was the object aimed at, without advancing them. Present quotations on Glass are as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; 100 boxes or over, 80 and 10 per cent. discount; less than 100 boxes, 80 and 5 per cent. discount. French Window Glass, 80 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ₱ lb.	....	@	$0.03½
Rubber Shoes, in ton lots ₱ lb.	....	@	.03

On What Basis Shall Cut Nails be Sold?

IN THE PRESENT confused condition of the Cut Nail market Nails are sold on three different systems. First the old Cut Nail card. Then at their meeting January 31, the Eastern Nail manufacturers adopted the National Price-List, which, however, has not come into general use. Again, at Pittsburgh February 15, at a meeting composed principally of the Western Nail manufacturers the Wire Nail card was adopted for the sale of Cut Nails, when the following resolution was passed:

Resolved. That the Wire Nail schedule of extras be adopted by the Cut Nail manufacturers and that such a card be issued immediately, and that each manufacturer of Cut Nails pledge himself and his company that he will not quote nor will he permit any quotations to be made for his account on any basis of average.

The fact that the Western makers have not regarded the National Price-List for Cut Nails with favor practically disposes of it for the present at least, and the action of the Eastern mills in following the Western mills in the adoption of the Wire Nail card, as is referred to under Notes on Prices, leaves the Wire Nail card, for the present, at least, as the basis for business in this line.

While there is a good deal of difference of opinion among the manufacturers of Cut Nails in regard to the proper basis for their sale, there is a general desire on the part of the trade to have some method adopted which will simplify matters, and if possible dispense with the troublesome though time-honored system of averages. The Cut Nail manufacturers are desirous, as far as possible, to meet the views of the trade in this regard, hoping that thereby the sale of Cut Nails will be promoted and the tendency toward the use of Wire Nails checked. At the same time they are naturally desirous of having some method by which they will be aided in obtaining a better price for Nails, it being conceded that for some time the sale of Nails has been attended with little, if any, profit, and in many cases with absolute loss.

In order to show the difference between the three methods of selling Cut Nails which are now before the trade, we give below the cost of an assorted carload, estimated in the three methods. The following is the cost of an assortment of 250 kegs on the old Cut Nail card at $1.40 basis, f.o.b. mill, with a 35 cent average :

3d	Fine,	10	kegs	$1.50 extra	$15.00
4d	Flat,	5	"	.60	3.00
4d	Common,	5	"	.60	3.00
5d	"	5	"	.60	3 00
6d	"	25	"	.40	10.00
8d	"	60	"	.25	15 00
10d	"	70	"	.20	14 00
12d	"	30	"	.15	4.50
20d	"	10	"	.15	1.50
40d	"	5	"	.05	.25
8d	Finishing,	10	"	1.60	16.00
10d	"	10	"	.85	8.50
60d	Common,	5	"		
		250	" at	1.40 basis	350.00
					$437.75

The following is the cost of the same assortment purchased at a discount of $1.25 from list, January 31, 1893, f.o.b. mill :

3d	Fine,	10	kegs	$4.00	$40.00
4d	Flat,	5	"	3.35	16.75
4d	Common,	5	"	3 35	16.75
5d	"	5	"	3.35	16.75
6d	"	25	"	3 20	80 00
8d	"	60	"	3.10	186.00
10d	"	70	"	3 00	210.00
12d	"	30	"	3.00	90.00
20d	"	10	"	3 00	30.00
40d	"	5	"	3 00	15.00
8d	Finishing,	10	"	3.20	32 00
10d	"	10	"	3.10	31.00
60d	Common,	5	"	3.00	15.00
		250			$772.25
250 kegs at $1.25 per keg					312.50
					$460.75

The following is the cost of the same assortment sold on the Wire Nail card at a base price of $1.25 :

3d	Fine,	10	Kegs	$1.60 extra	$16.00
4d	Flat,	5	"	.90	4.50
4d	Common,	5	"	.90	4.50
5d	"	5	"	.90	4.50
6d	"	25	"	.75	18.75
8d	"	60	"	.60	36.00
10d	"	70	"	.50	35.00
12d	"	30	"	.45	13.50
20d	"	10	"	.35	3.50
40d	"	5	"	.25	1.25
8d	Finishing,	10	"	.90	9.00
10d	"	10	"	.75	7.50
60d	Common	5	"	..	....
		250	"	at $1.25 basis,	$312.50
					$160.50

It will thus be seen that this lot of Nails costs approximately the same amount in the three different methods, the cost being as follows, in each case:

At the old Cut Nail card, $1.40 basis, 35 cent average	$437.75
At National Cut Nail Price-list at a discount of $1.25	460.75
At the Wire Nail card, $1.25 base	460.50

Trade Notes.

THE MONROE REFRIGERATOR COMPANY, Lockland, Ohio, make an announcement elsewhere relating to the Monroe Patent Stone-Ware Lined Refrigerator of their manufacture. The characteristics of this Refrigerator are noted in the text of the announcement.

KIRTLEY BROTHERS, 1213 Walnut street, Kansas City, Mo , in an announcement elsewhere show a sectional view illustrating Neff's Patent System of Elevating Water, and give a brief description of the system.

OATMAN'S ADJUSTABLE WROUGHT IRON EAVE TROUGH FASTENER is illustrated in an advertisement elsewhere, and a list of agents handling the device is printed in connection with the announcement.

THE UTICA, N. Y., PIPE FOUNDRY COMPANY have elected the following directors for the ensuing year: William M. White, Nicholas E. Kernan, J A. Williams, John L. Murray and Henry W. Millar. The board has organized by electing: Henry W. Millar, president; W. M. White, vice-president; John L Murray, secretary; N. E. Kernan, treasurer; inspectors of election, Charles I. Williams and John A. Kernan. The last year has been a prosperous one, according to the annual reports of the company. During the coming year the output will be increased between 40 and 50 tons daily, and 130 men will be employed during the entire year. Improved appliances are soon to be put in.

H. R. DE MILT & Co., 238 Water street, New York, announce to the trade that they have now in stock and ready for shipment the following brands of American Roofing Tin made in New York, namely: De Milt's First New York, De Milt's Manhattan, and De Milt's First New Jersey. These brands are stated to be a superior quality of Terne Plates. Messrs. De Milt & Co. are also sole agents for P. H. Laufman & Co.'s American Roofing Tin.

HUGH ARMSTRONG, Room 23 Laclede Building, St. Louis, Mo., has been appointed agent for St. Louis and vicinity for Gummey, Spering & Co., the proprietors of the Continental Tin Plate Works, Philadelphia, Pa. He will handle the various products of these works, which include the Eagle, Liberty, Phenix and Climax plates.

CINCINNATI MFG. COMPANY, Cincinnati, Ohio, issue a spring supplement, 1893 The supplement is devoted to Paint, Whitewash, Shoe, Scrub, Horse and Window Brushes, Cotton Mops, Whisk Brooms, Turkey Dusters, &c. Also, Nested Wood Bird Cages, Breeding Cages, Galvanized Poultry Netting, Screen Wire Cloth, Riddles, Sand Screens, Rat and Mouse Traps, Wire Moss Baskets, &c. A discount sheet accompanies the catalogue.

AMONG recently authorized corporations in Illinois are the following: Magney-Cate Mfg Company, at Freeport; capital stock, $50,000 for the manufacture of hardware specialties; incorporators, Rufus L Cate, Joseph P. Magney and Clarence E Calhoun. The Bradford Stove Company, at Chicago; capital stock, $100,000; for the manufacture of stoves and fittings; incorporators, Francis Jackson, Thomas E. Paxton and Arthur C. Conway. The Anderson Coke, Gas & Power Company, at Chicago; capital stock, $1,500 000; to purchase the patented inventions of James C. Anderson as far as they relate to coking coal and the recovery of the by-products therefrom ; incorporators, J. C. Anderson, J. F. Anderson and J. C. Cushman. The Excelsior Machinist Company, at Chicago; capital stock, $10,000; for the manufacture of machinery, tools and merchandise; incorporators, Reinold F. Paulson, Jens L. Christensen and Jesse Cox. The Ludowici Roofing Tile Company, at Chicago; capital stock, $40,000; for the manufacture of clay; incorporators, Henry B. Skeele, Harris Pomeroy and Charles W. Allen. The Gillespie Mfg. Company, at Chicago; capital stock, $50,000; for the manufacture of burglar alarms; incorporators, Henry R. Gulleepie, Thomas Robinson and Edward W. Gillespie. The Althouse Automatic Car Coupler Company of the United States and Canada, at Chicago; capital stock, $3 000,000; for the manufacture of cars, car couplers and railway supplies; incorporators, Henry Vincent, William Bannerman and John C. Amendt. Bracey Improved Spike Company, at Chicago; capital stock, $100,000; for the manufacture of railroad spikes and supplies and for general manufacturing; incorporators, M. J. Frost, B M. Taussig and W. N. Williams The Ruebs' Molding Sand Papering Machine Company, at Chicago; capital stock, $100,000; for the manufacture of sandpapering machines; incorporators, Lester A. Brown, Robert H. Wiles and Harry Bitner. The Lake Superior Fuel Gas Company, at Chicago; capital stock, $3,000,000; for the manufacture of fuel and illuminating gas, the erection of gas plants and the erection and operation of plants for the production of electricity for light, heat and power; incorporators, Faye Walker, Robert H. Harris and L. B. Langworthy. John A. Brown Novelty Company, at Decatur; capital stock, $18,000; for the manufacture of hardware specialties and stamped goods; incorporators, John A. Brown, Lewis S. Bonbrake and James L. Thayer.

ON FRIDAY of last week Robert L. Walker, president of the Youngstown Stamping Company, Youngstown, Ohio, and of the Girard Stove Works, at Girard, Ohio, made a personal assignment to H. K. Taylor of Youngstown, Ohio. As a result of the assignment of Mr. Walker, the Youngstown Stamping Company also made an assignment, and W. C. Hine, secretary of the concern, was appointed assignee. The Girard Stove Works also made an assignment, with assets stated at $30,000, and liabilities unknown. The Youngstown Stamping Company were established in that city on March 1, 1887, with a capital stock of $40,000, which was later increased to $50 000. When operations were first commenced only 25 persons were employed, but the business of the concern grew rapidly and at the time of the assignment about 150 persons were on the pay roll. The concern manufactured a general line of sheet metal goods and glass oil cans. It is thought an arrangement will be effected whereby the plant will continue in operation under the management of W. C. Hine, who has been secretary since the organization of the concern.

A CONVENIENT household article known as the hamper and toilet case combined is put on the market by the Folding Bath Tub Company of Marshall, Mich. The cabinets are made of ash with natural or antique finish, with the lower compartment for holding soiled clothes, pivoted at the bottom to fall forward. There is a ventilating flue at the top. It is designed to be placed in either bath or sleeping room, affording as it does a toilet case in connection with a hamper.

IT IS ANNOUNCED that the Stuart-Peterson Company, who recently sold their property on Noble street, Philadelphia, Pa., to Hoopes & Townsend, have purchased the large brick building of the National Bureau of Engraving Company, Burlington, N. J., and will remove their plant there in a few weeks. The building is now being put in readiness. The company, it is stated, will continue the

manufacture of Hollow Ware and Porcelain-Lined Goods, employing about 150 hands.

UNDER DATE FEBRUARY 15 the Iron Clad Mfg. Company, 22-24 Cliff street, New York, announce in a circular letter to the trade that they have commenced suit against the Haberman Mfg. Company for infringement of letters patent No. 296,206 of April 1, 1884, and No. 386,023 of July 10, 1888. The trial of this suit is to determine the questions of validity of the Iron Clad Mfg. Company's patents, and infringement by the Haberman Company.

THE STANDARD FIBER WARE COMPANY, Mankato, Minn., favor us with specimens of the wall calendars which they are distributing. These are composed of large cards, on the margins of which are printed numerous cuts of the company's specialties, making a very attractive border. The upper portion of the center of one of the cards presents a copy of Gerome's picture, "Last Prayer of the Martyrs." Another shows Herring's, "A Winter Farm Yard." Leaves for each month are attached to the lower part of the cards.

THE NUBIAN IRON ENAMEL COMPANY'S Works, at Cragin, Ill., were destroyed by fire on the 17th inst. The fire was discovered in the vat room at noon, and the Chicago fire department was immediately notified, but the icy condition of the streets and a blinding snow storm caused considerable delay in the arrival of the engines, and the works were completely destroyed. The loss on buildings and stock is stated to be fully covered by insurance. The manager, Charles E. Bonnell, is noted for his energy and enterprise, and it is not likely that he will suffer much time to elapse until manufacturing operations are resumed.

THE GOSHEN SWEEPER COMPANY of Grand Rapids, Mich., report having had a successful year in 1892, and are prepared to do a much larger business in 1893, having added materially to their machinery and other necessary fixtures. They, like some other manufacturers, are dissatisfied with the space allotted them at the World's Columbian Exhibition, claiming to have put in an application for 400 feet and being awarded but 48 feet of space. Other manufacturers of Carpet Sweepers have secured 80 feet, and the Goshen Company have concluded that unless they can have the same opportunity as their competitors they will save the money which will be required to make a creditable showing. They are still in hopes to have their space increased, as a number of applicants among their neighbors have concluded not to use the space awarded them. The number of improvements made in Carpet Sweepers by the Goshen Company within the past year have made them very popular with users, and they now receive a large quantity of orders by mail, whereas, when they first began manufacturing them at Grand Rapids, their business was entirely done by salesmen. They now have six representatives traveling from the home office, with selling agents in New York, Boston and Philadelphia, and expect to open an office and carry a stock in New York City at an early date.

A FIRM at Atlanta, Ga., engaged in the Tin Plate and Tinware business, as manufacturers and importers, write us under date of February 8th, respecting the business outlook in that section, as follows: "The South has had a spell of unusual depression, supposed by people generally to have been caused by the low price of cotton ruling for some time past. We are pleased to say, however, that the outlook is now much more encouraging. Reports from all sections of this and adjacent States where we seek trade indicate increase of business in the mercantile line, and good prospects for same in the future. Also good prospects in the way of building. Our own business for the month of January showed an increase of 60 per cent. over that of the corresponding month of last year."

JAMES A. COE & Co., Newark, N. J., well-known jobbers in Iron and Steel, have added a new department to their business and will hereafter handle and deal in Tin Plates. They have already arranged with one of the prominent manufacturers in the East for a Roofing Plate, which they are selling under the name of Staple. This is described as a high grade rolled Terne Plate, made by the palm-oil process and with a large percentage of Tin in the coating. Messrs. Coe & Co. intend to add immediately other brands of Ternes, as well as Brights, to meet the demands of roofers and sheet-metal trades for Tin Plates.

THE JOHN TORREY COMPANY of South Newmarket, N. H., send us circulars of what is known as Stovene Oil Stove Polish. It is said to be the great iron preservative and entirely different from any other stove polish offered to the trade. It is claimed that the oil in this polish does for the stove what clear oil does for paint. In the New Hampshire *Republican* of February 2 is a short article relating to the company, covering its location, officers, line of goods manufactured and prospects. In this article the superintendent of the factory, Daniel L. Langlands, is quoted as saying that the present output of the works is 12,000 boxes of Stovene daily.

NORTH BROTHERS MFG. COMPANY, Philadelphia, Pa., issue an oblong circular, bound in colored paper, which they entitled "Seasonable Hints for Household Use." The hints are in the line of recommendations respecting the Gem, Blizzard, American and other Ice Cream Freezers of their manufacture. They also show Ice Chippers, New Keystone Beater, Cake Pans and other articles. A price-list accompanies the illustrations.

H. R. IVES & Co. issue notice, under recent date, that, having resumed control of their business, they will be in a position to execute orders promptly for the coming season. The Longueuil works will be run mainly on staple hardware. Special lines, such as Mrs. Potts' Sad Iron, Iron and Brass Bedsteads, Iron Railings and Crestings, Hot-Water Heaters, Soil Pipe, &c., will receive particular attention.

AVERY STAMPING COMPANY, Cleveland, Ohio, issue a little pamphlet calling attention to a few of the articles of their manufacture in the line of Pressed and Stamped work. They add that they not only do all classes of Light and Heavy Blanking, Pressing and Stamping of Sheet Metal, but also build presses, dies and special tools for this class of work. The goods enumerated in the circular include Cylinders, Troughs, Tanks, Cones, Washers, Bottles, Hay Rakes and Harrow Seats. These goods are illustrated and price-lists given.

RAYMOND & CAMPBELL MFG. COMPANY, Middletown, Pa., make an interesting announcement elsewhere respecting the Sun Steam and Hot-Water Heaters (Lindemuth's patent) of their manufacture. The several advantages of the Heaters are referred to, and a variety of different views of the Heaters constitute the border of the announcement.

N. & G. TAYLOR COMPANY, Philadelphia, Pa., inform us that owing to their increasing business they have decided to open an office in New York City. They have secured facilities at 201 Water street, where in the future they will carry a full stock of their special brands of Bright Tin, Roofing Tin, Solder, Galvanized Iron and Tinners' Trimmings generally. The agency will be in charge of Benjamin B. Morrison, who is fully conversant with the trade in New York and vicinity, having been in their line for many years. Messrs. Taylor & Co. are also represented at Chicago, Omaha, Kansas City, Galveston and New Orleans, besides having numerous sub-agencies. They write us that their Tin-Plate works are in full operation and that the product they are turning out is giving full satisfaction.

Production of American Tin Plates.

We print this week the report of Special Agent Ira Ayer of the Treasury Department on the production of tin and terne plates in the United States during the quarter ended December 31, 1892. The results of the industry, as set forth in this document, may be regarded as eminently satisfactory. The amount of American tin and terne plates proper produced during the three months covered by the report was 19,756,491 pounds, of which a little less than one-third consisted of bright tin plates, as against 10,952,725 pounds in the previous quarter, or an increase of nearly 100 per cent., while the total of the two quarters combined was considerably more than double the whole production for the twelve months ending June 30, 1892. Of the tin and terne plates produced during the past quarter, 8,043,449 pounds, or more than 40 per cent., were made from American rolled black sheets and this amount is likely to be augmented during the current quarter. Thirty-two concerns are reported as actively producing, while ten more are preparing to do so. Eighteen firms are either making or are about to make their own black sheets for tinning; and of the entire product of tin and terne plates during the past quarter 91 per cent. consisted of the lighter class of plates, weighing less than 63 pounds per 100 square feet. A steady and regular increase of production, together with continued erection of new and enlargement of old plants, are features of promise marked by the report of Colonel Ayer.

A Late Spring.

Some weeks ago we remarked upon the then probable severity of the winter of 1892-93, basing the opinion that an unusually severe winter was likely to be experienced upon the fact that large quantities of snow had then already fallen over wide areas of country, and that sound ice of considerable thickness had already formed in large quantities. We, therefore, had accumulated in early winter—almost at the very beginning—a large store of cold, so to speak, which, when the sun should begin to return northward, would, like ice in a refrigerator, neutralize the effect of increased solar heat. The winter has been conspicuous for the infrequency and short duration of thaws; and now, having passed the threshold of spring, large quantities of ice and heavy snow deposits cover nearly all the more elevated regions of the Middle States, while over the Northern and Northwestern portions of the United States, and over the continent northward, wintry conditions stubbornly oppose the advent of spring weather. It is apparent that we may anticipate a late spring.

A Curious Effect of Snow upon Climate.

A curious effect of snow upon climate has been brought to light by observations of the scientist, M. Chaix, at Geneva in Switzerland. He carefully took temperatures of the air at four different hights, of granular, powdery and compact snow, and the surface of bare ground. At a hight of 39 inches and at a hight of 78 inches above the surface of the snow the mean temperature of the air was found the same, and this temperature was nearly always found to be very little higher than that of the snow surface, except when active thawing was in progress. With snow covering land to a depth of 5 inches, the surface of the ground was, on an average, 8 1-10° F. higher than that of the upper surface of the snow. But when the temperature of the surface of bare ground was compared with that of the snow, it was found that it was only 6½° F. higher than the upper surface of snow 5 inches deep. It was found that the presence of humidity in the air decreased the difference of temperature existing between it and the snow immediately below it, while in elevated regions, where air is pure and dry, the radiation of heat from the snow is so rapid as to widen this difference to a marked degree. As the air at a hight of 6 feet above the snow approaches nearly the temperature of the latter, the presence of large bodies of snow over wide areas must exert a great influence upon the climate even of regions where snow is not present, but situated so as to receive the winds blown from the snow fields.

How It Will Affect Trade.

A late spring always benefits the coal trade, particularly if it has been preceded by a hard winter. Prudent householders who practice purchasing a year's supply in the early summer will this year, many of them, find that they did not buy enough to carry them through; this will help to swell the spring trade, while the winter trade has already had an unusual demand from those who purchase in small quantities as wanted, such customers being a numerous class in all large cities. Some other branches of trade will be injured. With a late spring, summer follows so suddenly that articles produced especially for spring use are not bought at all by many who would otherwise be purchasers. The result upon all such branches of trade is usually a surplus stock to be carried over, and frequently sold at a much lower price than otherwise might have been obtained. Articles necessary to agriculture or the mechanical trades are very little affected by seasons. They must be had, all the same, though the demand for them may be somewhat retarded. This spring is likely to be fruitful of damage to property lying along strong flowing streams now firmly locked by ice, as present conditions are favorable for numerous freshets. Unusual delays in the opening of streams for navigation are likely to be the rule, and activity in commerce will thus be more or less obstructed.

Trade Education.

So much has been said and written within recent years—in *The Metal Worker* and elsewhere—about the value and necessity of better technical education for the training of good and efficient workmen, that it seems as if the subject had been so thoroughly threshed out that to refer to it again would be superfluous. Yet, in the opinion of quite a number of our readers, from whom we have recently heard, the matter still requires to be steadily hammered at, for "things are going from bad to worse." This is not our own croak, but it is the reiterated statement of a number of plumbers, tinners and sheet-metal workers, who are employers of labor, in various sections of the United States, and especially in the West. "Why can we not get competent workmen?" "Cannot something be done to raise the standard of the plumber, or the tinner?" as the case may be. These are the pertinent queries we continually receive. The pressing need of a better method of training the younger workmen in these and kindred crafts is evidently keenly felt. The incompetent workingman is a real grievance, and one that demands serious consideration.

The Solution of the Difficulty.

That there is a solution to the problem the records of the New York Trade Schools and its graduates amply prove. Those young men who have received the diploma of efficiency from that institution and who have gone forth to work at the trades there taught them throughout the country, are the best advertisement such a system could desire. A few weeks since we received a letter from a firm doing business in Colorado, in which it was remarked: "Through reading your articles on the New York Trade Schools we were induced to send a younger brother there to learn the plumber's trade, a step we have never regretted, as it fitted him to take charge of our work. He is to-day a first-class plumber." Cannot others similarly situated go and do

likewise? Of course we know that it is only the few who could afford to avail themselves of the New York Schools in this manner. What is really wanted is that similar educational institutions should be brought to them, or to within a reasonable distance of them, so that all beginners may at least have the opportunity of obtaining a thorough training in their craft, instead of picking up their knowledge haphazard, as they too often do at present.

Domestic Ventilation.

Although proper ventilation is receiving more of its due meed of attention in our public buildings and in the large new structures now being put up for office and other purposes, the public still remain, in large measure, callous and apathetic in this connection, when it comes to a question of the houses in which they and their families dwell and pass the greater part of their time. Why this should be so it is hard to say; but it is nevertheless a fact that even men who are particular about the due supply of fresh air in the places where they work during the day, are content to go home and pass their sleeping hours under conditions which are most unsanitary. Houses go up by hundreds in the cities in which no provision whatever is made for the proper circulation of air and the purity of its supply. In the majority of rooms in city and suburban dwellings, during the winter at least, the only source of air supply of any kind is the register, and the air has to escape as it best can through an occasional open door or window, or through any cracks and crannies it may find. The only method of insuring ventilation is the primitive one of opening the windows, and that is not always comfortable or desirable during such severe weather as this winter has brought with it. Especially is this felt at night, where, in a small room, the choice has to be made between inhaling the atmosphere laden with impurities, or sleeping near an open window, with the chance of being snowed under or blown out of bed by a sudden change of weather. Now, it is perfectly feasible to so build a house as to insure this desirable feature of adequate ventilation. Every dwelling should be provided with a proper air shaft, with connections from each room, or flue to carry off the heated and vitiated air which accumulates there.

Unhealthy Sleeping Quarters.

A simple test, which we have seen carried out, should convince the most apathetic of the necessity for a better air supply. Take some of the condensed breath collected on the cool window panes of a room where a number of persons have been assembled, and burn it. It will smell like singed hair, showing that organic matter is present in it. But further, let the condensed breath remain on the windows for a few days and then examine it under the microscope, and it will be found to be alive with animalculæ. It is the inhalation of air containing just such putrescent matter that is being carried on in most of our sleeping rooms night after night in the cold weather. This is the secret of much of the lassitude and headaches felt in the morning, in place of the refreshment which sound sleep should bring. The agitation for fresh air is no "fad." It is an all-important question which needs to be impressed again and again upon the minds of this generation.

Liability of Employers for Accidents to Workmen.

The vast majority of manufacturers are sure to be confronted, sooner or later, with the question as to what they propose to do to recompense an employee who has been injured while in their service. While they may employ every guard and safety device known, and while they may repeatedly caution and conspicuously post printed directions, a more or less serious accident is bound to come.

Accidents occurring in the ordinary machine shop may be said to be due to one of the three following causes: Where it is of an unprecedented nature and could not, therefore, be foreseen and guarded against; when long familiarity with a machine has rendered the operator careless; and finally when, through innate wickedness and perfect laziness, an employee deliberately permits himself to be mutilated, trusting in the prospective suit for damages for his reward. With the second of these conditions we are all acquainted and have seen examples.

As illustrations of the first and third conditions, it is only necessary to mention two cases recently described to us by the proprietor of one of the most prominent machine tool manufacturing establishments in the country. A certain portion of the upper surface of a large casting was being planed. At the end of one of the cuts a piece was detached from the corner of the casting with such force as to permanently injure the eye of the operator, who chanced to be in range. This was one of those strange occurrences that could not be provided for. The firm promptly provided for the relief of their injured workman. The next case, in illustration of the third condition, was injury caused by a large traveling crane. An employee deliberately put his hand upon the track and permitted the wheels to run over it. There was no sudden alarm, of any description, that would offer a reasonable explanation for his seeking support and placing his hand upon the track. His employers conceived that his action was deliberate and the matter was taken to court.

That the employer of men in almost every industry understands perfectly that those working for him may be injured is conceded, as is also the fact that it is the exception when an employer is not willing to repair, as far as lies in his power, any injury to one of his men.

A phase of this subject, more particularly applied to miners, is discussed in a recent editorial in *Engineering*. Our contemporary reviews the German law covering assurance against accident, which has been established about seven years. Employers are compelled to provide an insurance fund from which to reimburse those of their employees who meet with accidents, however they may be caused. In England employers and employed carry on joint funds for insurance against accidents in mining industries. Commenting upon the German method, our contemporary says:

> The most striking feature of the German system of State insurance against accidents is the serious increase of cost that it has entailed from year to year upon the employers, who are compelled by law to provide the whole of the funds required. This is the essential difference between the German system and our own.
>
> In other words, one is compulsory and the other voluntary, as far as the employer is concerned.
>
> Generally speaking, in the absence of State compulsion, the two classes concerned are in Great Britain ready to share the burden, and in the mining industry a considerable part of the workman's earnings are regularly set aside to make this provision. The employer is generally ready to add to whatever fund is thus established, a moiety, at least, of the amount provided by the workmen, and the fund being jointly administered, it affords a desirable and a useful opportunity of bringing the two sides together and enabling them better to understand and appreciate one another. The funds provided in this way in the principal mining districts have been very considerable, but in some localities the recent course of the fund has not been satisfactory. . . .

Mr. Chamberlain would make employers wholly and solely responsible for the indemnification of those who suffer accidents in their employ, and he suggests that the tax so levied upon capital should be recouped by an increase of the price of the commodity produced, so that, in the long run, the expenditure incurred should be paid by the general public as consumers.

The question is a debatable one in almost all industries and in every country largely interested in manufacturing. The exact relationship of the employer to the employee—accidents to the latter only considered—and the proper grading of the nature of the accident, and the "contributary negligence" of the employee himself, are the most important factors of the problem. We do not think these points can be satisfactorily settled by any arbitrary arrangement such as is proposed by the German law.

Crinolines and the Iron Trade.

The rumored revival of the crinoline suggests the possibility of a new impetus being given to that branch of the iron trade which profited so largely from the adoption of this fashion some 30 years ago. Fortunes were made in the hoop-iron business when the metallic crinoline was last in vogue, and it is quite likely that manufacturers of this material may come in for a good thing again. Whether the distension of the female skirt would add, however, to the happiness and content of the race at large is questionable. When we recall the satisfaction with which the average "male creature" contemplated the passing of the crinoline fashion many years ago, we rather incline to the opinion that the resurrection of this article of apparel would not be regarded with the same equanimity by those whose recollection carries them back to the time when they suffered from its inroads on their comfort and convenience in the days of old. In public conveyances, churches, theaters and meetings of both sexes, social and otherwise, its existence was wont to be exceedingly palpable. And how would the fashion accord with the city crowds of to-day? How would a bevy of "be crinolined" fair get on, for example, amid the crush and push prevailing on the elevated railroads of this city, or the Brooklyn Bridge, every evening? It would be an interesting problem to calculate how the already congested condition of these and similar city outlets could be modified to admit of the accommodation of a few thousand iron-circled skirts a yard and a half in diameter. No, we cannot think that even the hidden autocrats, who rule the world of fashion, could be heartless enough to inflict such suffering upon humanity as would result from the wholesale adoption of the time-honored crinoline. However, if the fiat goes forth, and it *must* come, there will be some at any rate who may rejoice. The hoop iron trade will have cause to be exceedingly glad. But such is the innate selfishness of the majority of men, that it will not, we fear, be considered an unmixed blessing by those not directly interested in the manufacture of this product.

Governor McKinley is involved to the extent of about $100,000 by indorsing for Youngstown manufacturers, but friends come nobly to the rescue.

THE LETTER BOX.

Deafening for Floor.

From D. M. F., *Brook, Ind.*—I have put an iron ceiling below the floor separating a general store from a public hall. As a deafening of some kind is required, I propose putting a layer of 3 inches of mortar and sawdust on the iron, but the owner of the building is not satisfied with the plan. What method would be better?

Answer.—A layer composed of 3 inches of mortar and sawdust might answer as a deafening when laid directly on the iron, providing the iron was secured to the joists in such a manner as to resist the weight and there was no danger from the moisture contained in the mixture causing the iron to rust. This danger could be obviated by putting in a false floor between the joists upon which the mixture could be laid. A common method is to first lay a floor on the joists, then lay strips of wood ⅞ x 2 or 2 x 2 inches on the floor, above and parallel with the joist. The spaces between the strips are then nearly filled with a mixture composed of cinders and mortar, after which the floor is laid. There are a number of kinds of deafening felts that can be placed between the floors that are said to answer the purpose. Another material, and one that is highly recommended, is mineral wool. The spaces between ceiling and floor can be entirely filled, or a false floor can be laid between the joist, so there will be about 2 inches of mineral wool used.

A Problem in Algebra.

From H. M., *Paxton, Neb.*—Please solve the following algebraical problem in *The Metal Worker*. The problem is: Given the remainders of any unknown quantities, with divisors of 3, 5 and 7, to find the unknown quantity. In the case in mind, the remainder with divisor 3 is 2, with divisor 5 is 3 and with divisor 7 is 1. Expressed algebraically it would be:

$x - 3a = 2$, $x - 5b = 3$, $x - 7c = 1$.

Answer.—It is impossible to answer our correspondent's inquiry unless he lets us know the value of a, b or c. Take, for instance, where 3 is contained into x a times with a remainder of 2. If he lets us know how much a is, it is very easy to find what x is equal to. Assuming that a is equal to 2, therefore, and substituting in the first equation, we have:

$x - 3$ times $2 = 2$, or $x - 6 = 2$, or $x = 8$.

On the other hand, if we assume that N has any value, say 5, for instance, it will be easy to solve for the other letters, and we have in the three equations:

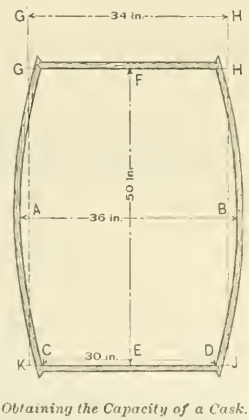
$$a = 1,\ b = \tfrac{1}{2},\ c = \tfrac{1}{4}.$$

To put the case very simply, the following arithmetical rule covers it: Multiply the divisor by the quotient; add the remainder, and the result is the given quantity. All these suggestions, however, do not cover the point. The fact is that we have three equations with four unknown quantities given by our correspondent, and in such a case the unknown quantities cannot be found. It is necessary to have as many equations as unknown quantities for an algebraical solution.

Obtaining the Capacity of a Cask.

From N. O., *Camden, N. J.*—I would like to have a method published in *The Metal Worker* for obtaining the capacity of a barrel or cask in cubic feet, cubic inches and gallons. The curve or bulge of the cask is what bothers me.

Answer.—One method for obtaining the capacity of a barrel or cask is to determine the size of a cylinder having the same capacity as the barrel or cask, and then obtain the contents of the cylinder.



Obtaining the Capacity of a Cask.

Take for example the cask shown in the accompanying diagram, in which A B represents the bung diameter, C D, the head diameter, and E F the length. A cylinder having (nearly) the same capacity as cask is indicated by G H J K. The diameter of this cylinder, G H or G H, represents the mean diameter of cask. The mean diameter of a cask is found by adding to the head diameter two-thirds of the difference between the bung and head diameters, or if the staves are not much curved, by adding six-tenths. This reduces the cask to a cylinder.

In the diagram, the bung diameter of cask is 36 inches and the head diameter 30 inches. The difference between the two is 6, and two-thirds of $6 = 4$. This number is to be added to the head diameter of cask. Then $30 + 4 = 34$ inches, the mean diameter of cask. Then to find the contents of cask shown in diagram we have simply to find the contents of the cylinder G H J K, which is (nearly) the same capacity as the cask. In performing the operation, if the dimensions are given in inches, the result will be in cubic inches. If the dimensions are given in feet and fractions, then the result will be in cubic feet. As there are 231 cubic inches in a gallon, the former method may be found the most convenient.

To find the contents of a cylinder, multiply the area of the base by the hight. To find the area of the circular base, multiply the circumference by one-half the radius. To find the circumference of a circle, multiply the diameter by 3.1416. By the above rule it is necessary to find the circumferenceof the circle in order to obtain the area. This is obviated by another rule, which is as follows: To obtain the area of a circle (base of a cylinder) multiply the square of the diameter by the decimal 0.7854. The square of a number is obtained by multiplying the number by itself. Then to find the contents of a cask in gallons, we multiply the square of the mean diameter by 0.7854, and the product by the length. This gives the contents in cubic inches. Then, by dividing by 231, we obtain the contents in gallons. A more convenient way of performing the operation is as follows: Multiply the length by the square of the mean diameter (in inches), then multiply this product by the decimal 0.0034. The product will be the contents in gallons and decimals of a gallon.

Flux for Soldering Roof.

From W. C., *Jacksonville, Fla.*—I see by the Letter Box article on soldering a roof, contributed by "B. E. H.," Philadelphia, in *The Metal Worker* of February 11, that he has been somewhat troubled with a tin roof rusting out every three years. If he has to put on the roof again, as I think he will probably have to do, I would advise him to cover the roof first with some kind of building paper, then put on the tin, and he will not be troubled so soon with it wearing out. The paper will prevent the dampness condensing on the under side of the tin and rusting it. I have used it a long time here and find it better than painting the under side of the tin. But do not use tar paper. I have used sperm candle as a flux occasionally, and have always found it to work well.

Removing Water from Cellar.

From J. E., *Confluence, Pa.*—I have a wet cellar that has at present from 4 to 8 inches of water in it. We cannot drain it on account of the cellar being lower than the high-water mark. The water comes in from the lowest point of cellar and at a point to which the floor drains. No water comes in through the side walls. Do you know of any arrangement for lifting the water and throwing it out that does not depend upon city water pressure, or can you suggest any remedy for the difficulty?

Note.—Our correspondent's reference to high water is evidently the high water of some neighboring river. If it was tide water it would be a simple matter to put in a drain with a back-water valve, so that the cellar would drain at low water, and nothing would enter at high water

However, that suggestion is impracticable, and likewise it does not appear that the cellar drainers on the market would be of use, from the fact that they depend upon water or steam pressure for operation. To remove the water, we fear our correspondent will have to use a pump or bucket, and as to the prevention of the evil, perhaps a coat of Portland cement on the cellar floor would prevent the inflow of water. We submit this question to our readers and trust that those who can will assist with their experience.

Roofing Cement.

From O. B., *Cincinnati.*—There are a great many tin roofs so old that they cannot be patched with solder, in which case I use cement. I find, however, it is pretty expensive to buy it all mixed and would like to know some receipt for making a roofing cement of good quality. I would like to mix it in quantities of 50 and 100 pounds.

Will Somebody Tell Him?

From O. I. C., *Clearwater, Ill.*—As your paper is quite interesting reading, many an old, experienced hand will probably see this, and can, if he will, give for the benefit of the craft at large the proper size for a hot-air pipe leading from the furnace to heat a room 15 feet square with a 10-foot ceiling. I don't want the cut and dried observation of the pen and ink expert that the question is vague, and it depends on conditions, &c. The question is asked just as a young workman asks his boss, and the boss has to answer it by taking in all the possible conditions and telling him how to provide for every one of them, bay window and all. I want just that kind of instruction in the hammer and shears style from the know-how of those who have done the work and felt the consequences. I have been waiting some time for things to get a little quiet in the shops all through the country, so my question would receive attention and the old hard workers would have time to write the size they would use under different conditions, with the conditions and the why of them. They have some advanced laws on heating in Massachusetts, and I hope some Yankee will give us a line and that your paper will be pushed a little for space to give us all a little education.

Preserving Tin Roofs.

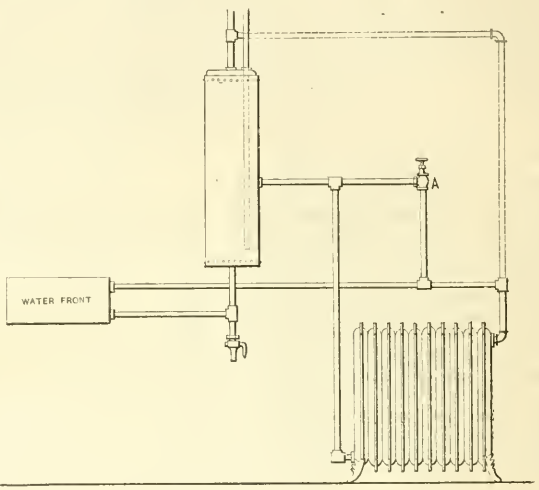
From E. F. B., *Greenville, Pa.*—In answer to the question of "C. L. F.," who asked what good the sand will do on the last coat of paint on a tin roof, would say that if the painting and sanding are properly done, the sand will form a solid body on the surface which will protect the roof. Were your correspondent here I could show him a roof made in this manner 22 years ago, which has never been painted since and is still in good condition.

Leaking Cans.

From J. W., *Wappinger's Falls, N. Y.*—In *The Metal Worker* of April 20, 1889, you will find a letter from me describing the same trouble that "G. A. K.," of Akron, Pa., whose communication was published in *The Metal Worker* February 18, 1893, complains of. I wrote for help to my fellow-craftsmen, but received none. I asked a manufacturer of acids, who is also an expert lead burner, what to do, and he advised me to wax the joints. Later I had another 14-ounce copper tank, 3 x 4 feet, double seamed and locked, with corners heavily soldered inside and fitted tightly in a wooden box made of 2-inch boards. This tank sprang a leak on me and I discovered that the solder was all gone from some of the seams. Instead of trying to resolder them I simply warmed the seams with a gas jet and waxed them smoothly with common beeswax, and I have had no trouble since. The water used in the tank was well water pumped in through iron pipes. Your correspondent at Akron will find that wax will resist any acid and is available for cold water tanks.

Radiator and Water Front.

From J. G., *Philadelphia, Pa.*—I would advise "F. P.," East Fairfield, Vt., whose inquiry appeared in *The Metal Worker* of February 11, to arrange his radiator and circulating boiler as shown in the inclosed sketch. He should use not less than 1-inch circulating pipe and locate at the highest point of the top circulating pipe to radiator, a vapor pipe of about ⅜-inch internal diameter, and carry it to a point above the supply tank of the boiler or into the hot-water pipe, as shown in dotted lines. In running the pipes care should be taken to grade them, so that no steam or air can be lodged in them. This arrangement will give all the circulation he desires at the radiator and also at the boiler, if the water front is a good one. The angle valve marked "A" may be opened for summer use when the radiator is not required. If both the radiator connections are at the bottom of the radiator, then he must run an air pipe from the top of radiator and connect it with the air pipe shown in the sketch.



Radiator and Water Front.

A Word to Apprentices.

From E. B. H., *Carmel, Maine.*—I wish to say a few words to the young men who are now serving apprenticeship at the tin business, and who do not have the advantages of the trade schools which are located in several of our large cities. It was my lot to learn the trade in a country shop of a man who was a very good workman, but who did not know or care much about the art and science of pattern cutting. He had been in business some 15 years, and did not have a treatise on pattern cutting of any kind, nor did he take a trade paper. Consequently, what I learned about pattern drawing I had to pick up myself. I learned many problems in this way: I purchased a book on pattern cutting, and after my day's work was done would take a sheet of paper and square and compasses and sit down at the bench and would draw a small design from some one of the problems. I continued in this way until I had mastered all the problems in the book. By following this plan the young apprentice will be surprised at the short time it will take him to become acquainted with the principles of pattern cutting and the vast amount of valuable knowledge he can acquire. It also has this great advantage—it sets him to thinking how to lay out work for an odd job that may come in; and also when he has a job that requires drafting it teaches him to rely on himself. It is a good thing to have help in the study of pattern cutting; but remember that if you take no interest in such work it makes no difference how much help you have, it will do you no good, while if you go at it alone every problem you master will be impressed on the mind and will always be ready when wanted.

Size of Coil Radiators.

From T. F., *New Prague, Minn.*—I wish to know the rule by which I can find how many lineal feet of 1-inch pipe of a hot-water system will be required for a given size of room. I would also like to know how many lineal feet of 1-inch pipe I should use for a given sized room in a heater exclusively made of 1-inch pipe with return bends and branch tees for circulation.

Note.—Our correspondent has not given sufficient particulars for us to answer intelligently. The size of a room is not a safe basis for calculating the amount of heating surface required. The location of a house, the material of the walls, and more especially the exposed glass surface of a room, have a great deal to do with the question of heating it. A certain size of room, for instance, in a house with walls packed like an icehouse would require very little heating surface, while a conservatory of the same capacity would require a great deal of heating surface. As a rough guide, we would say it has been recommended to use 1 square foot of hot-water radiating surface for from 30 to 50 cubic feet of space in dwellings. Figuring on 4 lineal feet of 1-inch pipe to a square foot of radiating surface, our correspondent can make the necessary deductions. As to the size of boiler surface for a given quantity of radiating surface the authorities differ, one well-known rule being 1 foot of boiler surface to every 40 square feet of hot-water radiating surface.

Roofing Contracts.

From H. C., *Pittsburgh.*—"J. J. B.'s" inquiry in *The Metal Worker* of February 28 about roofing contracts started me a-thinking, and I will give you my experience with a verbal agreement.

A party whose name and business I knew and with whom I was on speaking terms (an acquaintance only, no friendship, no knowledge of his standing) came to me stating that he was building two houses out of town and was recommended to call on me in reference to putting in the heating and cooking apparatus and doing the necessary roofing, &c. Who sent you? was my first question. He gave me the name of one of my best customers, one who has given me many a pointer when I needed them in my earlier years, and who is a leading dealer of this city. He also gave him as reference. I went to see the buildings. They were just started. He showed me the plans, but they were worthless. No one could make head or tail of them, neither the owner nor the carpenters. I asked for the size of the buildings and he gave me them. The total square feet over all, allowing for all projections of cornices, &c., was 1500 square feet, with 28 feet of leader. They were to be 5-room houses.

I gave him price on heating same; specified the ranges and also set price: and he said: "That is satisfactory; we will send you word in a few days, for the roof is ready, so that you can be prepared." I then said, "I will send you specifications and estimate what I intend to furnish, and what I will do for that money, and you send me acceptance." That, he said, was not necessary; he was not afraid but I would do what was right. "Well," I said, "now if your houses are any larger than the sizes you gave me I will charge you so much per foot extra. That is what I am figuring on; and the leaders must not exceed 28 feet; and if they are smaller I will allow you the same. There must not be over five runs of pipe from each heater, or I will charge you so much per foot extra; or, if less, I will credit you with the difference." I went over the estimate item by item, and he was perfectly satisfied with my terms—payments to be made as work progressed, and 20 per cent. to remain until houses were finished, as a guarantee of good workmanship, &c.

I started. After a few days' work my foreman sent me word that there was not enough tin. Strange, I thought. I went out and saw the brother of my customer, who was part owner and the paymaster of the firm. "Oh, that will be all-right," was his response. I finished the roofing, 3368 square feet, and 108 feet of leader. I measured the job, handed the measurements to the brother, and called his attention to the difference. He said, "We thought while we were about it we would give ourselves plenty of room, and altered the plans." No money yet! The partition studding was put up, and call made for pipes for heating. Out I went, ten rooms instead of five. I called the boss carpenter's attention to it. He was the father of the owners. He called in the paymaster, who said, "I suppose it is all right; the house will have to be heated, and if it is extra, of course that is all right." In went the pipes. No money yet!

I then stopped, requested some cash and got 50 per cent., and the promise that as soon as heaters were in I should be given the other 30 per cent. A heater intended for five rooms won't heat ten. Without asking any questions, I put in one large enough. Instead of six registers in each house I put in 11 and refused to put in ranges on account of so many changes, and not seeing more cash. I got done and presented the bill to the one I made the contract with.

Bill disputed! Would not pay. His excuse was, I had no authority to do any more than I had agreed to do. His brother or father had no authority to order it and he would not pay one cent over or above the contract.

I employed an attorney, started suit, filed lien, &c. Found out that there was $6000 of judgments ahead of me. They made their defense, filed affidavit, &c. I was not satisfied with my attorney's opinion and got another opinion. Both opinions were that he would beat me. I should have made a new contract, or have stopped. They offered 60 per cent. in settlement, and under advice of my attorney I accepted it and was glad to get it. I thus got a larger percentage of my bill than a few others. After the smoke cleared away I figured the second time. Result: net loss, $134.50. My first figuring showed a profit of $60. I have no comment to make.

Exhaust Blowers in Planing Mills.

From M. F., *Cincinnati, Ohio.*—Please tell me how to construct the blow pipes used in planing mills and other woodworking machine shops for taking up the shavings and dust. What size is necessary for the different machines and what size of blower in speed of fan is required?

Answer.—The piping used for removing chips, shavings and sawdust from woodworking machinery, although sometimes made of wood (and, therefore, rectangular in section) is almost universally constructed of galvanized iron of sufficiently heavy gauge to withstand the wear of the material passing throught it. The size of the pipe should be proportioned to the amount of material passing through it. In ordinary practice the following sizes of pipes will be found to be most satisfactory for the respective machines:

Surfacers or matchers, upper hoods, 7-inch.
Surfacers or matchers, lower hoods, 7-inch.
Surfacers or matchers, side hoods, 5-inch.
Double surfacers or matchers, upper hoods, 8-inch.
Double surfacers or matchers, lower hoods, 8-inch.
Double surfacers or matchers, side hoods, 5-inch.
Tenoners, 6-inch.
Pony planers, 6-inch.
Rip saws and resaws, 6-inch.

These sizes, which are for medium-size machines, may be varied somewhat in accordance with the size of the machine, but a pipe less than 5 inches should be avoided. Sweep up pipes should not be less than 6 inches.

Great care should be taken in the construction of the hoods, bearing in mind the principles that they must be as closely fitted as possible around the cutters and that their cross sectional area must not be increased so much as to decrease the velocity of the air which passes through them and thereby cause the shavings to drop rather than pass up the pipe.

The pipes from the hoods if carried up to a main pipe above, should enter on the side, not on the top, and all pipes should have easy bends, the internal radius of all elbows being equal to the diameter of the pipe. To select the proper size fan, add together the areas of all the branch pipes to the hoods and then choose from the manufacturer's tables a fan whose inlet has an area equal to this combined area.

This method will secure satisfactory results, notwithstanding the fact that some manufacturers or agents recommend that the fan be about 2 inches less than the diameter thus found, while others recommend that it be about 20 per cent. larger.

The truth of the matter is that the larger the pipe that will satisfactorily convey the material, the less the power required, provided the same volume of air is moved under the differing circumstances. Power will be saved by placing blast gates in the hood pipes, so that they may be closed when not in use.

Fans are usually speeded at from 4 to 6 ounces pressure, according to character of the shavings, the heavier shavings calling for the higher speed.

The practice should always be followed of placing the fan as near the work as possible and letting the greatest length of pipe come on the delivery end between the fan and the point where shavings are deposited.

As slight errors in design of piping system, selection of fan and speed at which it runs may seriously affect the amount of power consumed—which is never small—it is usually best to avail one's self of the experience of the manufacturers of planing mill exhausters, who are generally perfectly willing to give all needed advice to a customer.

Practical and Theoretical Furnacemen.

From J. P. C., *Roxbury, Mass.*—I saw a statement some time ago that it wasn't necessary for a man to be a pounder of tin to be a furnaceman. It may not be necessary to be a pounder of tin, but I claim that a furnaceman should have considerable knowledge of the business, and also be a practical mechanic. I have seen so much of those men who are not so that I wouldn't have them round for a moment if I could get a practical furnaceman. If they would sell a furnace, and stop at that, it would be all right. But after awhile they will go and set a furnace in a cellar, and call a tinman and tell him what to do. There's where the mistake comes in. The tinman knows more about the furnace in an hour than the salesman would know in ten years, and it is discouraging to him to receive instructions from such men. There is always more or less trouble with the work, and the employer is put to unnecessary expense. I don't think much of mere book-read mechanics; and the reason such men get into the furnace business is because the employers are usually not mechanics themselves. The young men taking their fathers' places as employers are still less so. Because they have been educated at college and think they know enough, they won't trouble to acquaint themselves with the tin shop and other business. They employ the class of men I speak of, between the workmen and themselves, to the disadvantage of both parties. At any rate, that is the state of affairs in Boston, I am sorry to say, as all tinmen will testify. It seems to me that the less a man knows about the furnace business the better he is off if he wants to make a living at it. These theoretical men seem to know as much about a furnace in fifteen minutes as a practical man would take five years to learn. I have seen carpenters fill the position—or try to do so—also brickmasons, at various times. So it seems to me if a man wants to be a furnaceman, he had better learn some other trade outside the tin business."

Says a correspondent of a foreign hardware journal: "A friend of mine bought some waste tin plates from a manufacturer, and after examination wrote to the maker saying they were simply scraps of tin plate packed in boxes and fit for nothing but to cover bungholes with, and asking what the maker was prepared to do to fulfill his contract properly. To this the diplomatic maker replied that he was obliged for the letter, and would advise his friend to use the plates for covering bungholes, as they seemed so suitable for that purpose. The joke was too good to annoy even the buyer."

WORLD'S FAIR NOTES.

Labor Troubles.

The first labor organization to attempt a hold-up at the World's Fair, with the necessity of being ready by May 1 as the club, was the Electrical Wiremen's Union. The attempt was a flat failure. Director of Works Burnham anticipated the announced strike last week by having all the electrical wiremen in the employ of the exposition to assemble at the Transportation Building. There he made a short address. He told the men he would not be forced to pay equal wages to all; that some earned more than others and were entitled to more pay. When Mr. Burnham had concluded he asked all who wanted to leave to go to one side of the aisle and those who wished to remain to go to the other. The men separated, sixty nine desiring to go and fifty-five to remain. The sixty-nine were paid off and at once left the grounds. At the same time 140 employees of the insulating company, which has the subcontract for stringing the wires for the Westinghouse Company, quit work.

The demand of the union upon both the insulating company and the exposition was the same, being for uniform wages of 37½ cents an hour, time and a half for overtime, and double time for Sunday work.

The pay roll of the Exposition shows that of 69 strikers 43 received 31½ cents an hour, 11 30 cents, 12 35 cents, 1 50 cents, and 2 25 cents. The force had been working nine hours, with time and a half for the last hour, making the daily wages $2.99 for 43 of them.

The strike contagion did not manifest itself anywhere else on the fair grounds, and officials are hopeful of quarantining against it. The bad weather has delayed in some degree a good deal of work on the grounds, and this loss must be made up in short order as soon as the snow and frost disappear. The most important point just now is Machinery Hall, where a force of 325 men is engaged in preparing the foundations for the heavy machinery. Any delay in this work would be critical, as all the time remaining is needed to get the machinery into place.

The work of constructing the exhibit pavilions in the Manufactures Building is being rushed forward as though May 1 were two weeks instead of two months in the future. In fact this particular branch of construction work is being hurried along in every department, but so great is the main building that particular attention is paid to that.

Passes and Admission Tickets.

Sixty thousand passes will be issued by the exposition management to the fair next summer. Every person of prominence who might be expected to have a free admission will secure it. The bulk of the passes will, however, go to the 45,000 exhibitors and their employees.

Each one of these passes will bear the picture of its holder. Within a few weeks a circular will be issued to those entitled to these free admissions and requests for their photographs be made. These will be taken to Jackson Park, rephotographed to vignette size, and then placed on the cover of the pass book. These pass-books will contain one coupon for every day of the exposition and one must be torn off for every admission. In case the holder leaves the grounds within the day he will be given a return check.

Monthly peauss will be issued to employees of exhibitors. They will be renewed every 30 days, in case the bearer retains his connection with the exposition.

Aside from the passes there will be two sets of admission tickets. The first will be handsomely engraved and suitable for souvenirs. They will be issued in four series, one bearing the head of Columbus, the second that of an American Indian, the third that of Washington, and the fourth the picture of Lincoln. These will be placed on sale by April 30. It is thought that they will be largely purchased and retained as souvenirs, and to complete the series the investor must expend $2. These tickets will not be sold at the gates, but at designated downtown places.

The gate tickets will be less artistic affairs and probably be good for one day only. The others are to be good for any day.

The Steam Boiler Fight.

The Stirling Boiler Company have reason to feel elated over the latest development in the famous boiler controversy. Last week Judge Grosscup of the United States Court, to which the case had been transferred, refused to grant the injunction asked for by the Babcock & Wilcox Company against the World's Columbian Exposition Company and others, restraining the fair officials from allowing the Stirling Boiler Company to place an exhibit of boilers alongside the Babcock & Wilcox Company exhibit in Machinery Hall. The reason given was that the complainants were to have the remaining space if the fair needed additional boilers. An agreement with Mr. Sargent, representing the Chief of Construction, was the basis of the complaint. In his decision, Judge Grosscup held that there had been no agreement and that the court could not interfere with the discretion of the Director General. Again, the supposed privilege had not been submitted to and approved by the Council of Administration. Sargent had no right, the court held, to grant such a privilege. After stating that the Babcock & Wilson boiler plant was acknowledged to be an exhibit, Judge Grosscup says:

"Nothing is clearer than that the installation of the exhibits is exclusively within the control of the commission. In this respect the local corporation and its agents have no authority."

The Ferris Wheel.

On the Midway Plaisance there will be an exhibit which is intended to rival in novelty the Eiffel Tower. This will be the Ferris wheel. Its diameter will be 250 feet. The wheel is intended to convey passengers around a circle in cars, from which visitors will have a full view of the exposition grounds and buildings The wheel will be 264 feet in hight. Around it, suspended between the two crowns by steel trunnion pins, will be 36 passenger cars with a seating capacity of 60 persons each. The entire structure is of steel and somewhat resembles a huge bicycle wheel revolving between two towers. The principle of coostruction is somewhat similar to an old style English breast water wheel in that it consists of a stiff outer crown, which is suspended from the center axle by a system of tension rods. The wheel practically consists of two wheels placed on the same axle, spaced a distance of 28½ feet apart and held together by struts and ties. The great axle is the largest piece of steel ever forged in this country, being 33 inches in diameter, 45⅛ feet long, and weighing 56 tons.

The axle is supported by means of steel towers 137 feet high. These are each supported by four legs, two vertical and two inclined, connected at the base by eight huge portal struts, thus forming an almost solid arch of steel. The foundations of masonry beneath the tower taper from an immense base to a hight of 18 feet and under this are piles and concrete. Passengers, while indulging in their novel trip, will be just as safe as while riding out to the grounds on a railroad train. Arranged in groups on the rode around the crown of the wheel are 3000 incandescent lights of various colors. These will be alternately extinguished and relighted at night as the wheel revolves. The engines which are to revolve this structure are in themselves an object of interest. They consist of two link-motion reversible eogines of 30 inch bore, 4 foot stroke and 2000 horsepower.

The Ferris wheel is to be located in the middle driveway of the Midway Plaisance, about 100 feet from one of the entrance gates. The driveway divides at the wheel, and passing on both sides converges after the wheel has been passed. It is the personal invention of G. W. G. Ferris, a bridge engineer of Pittsburgh and head of the firm of G. W. G. Ferris & Co. Robert W. Hunt of the Robert W. Hunt & Co. Inspection Bureau is president of the Ferris Wheel Company.

For Bicycle Enthusiasts.

Nearly 60,000 enthusiastic bicyclists make their homes in Chicago and vicinity, and it is in recognition of these and the wheelmen of the entire country that the exposition authorities will establish two bicycle courts at Jackson Park. In making this arrangement, too, it is estimated that the passenger transportation problem will be made easier of solving. Days of special importance will see 10,000 wheelmen at the park, who would, only for the bicycle courts, be compelled to depend upon the already overcrowded cars and steamboats. These courts will be of sufficient size to accommodate 8000 wheels. They will be each 200 x 40 feet in dimensions, covered with glass, and built on rather unpretentious lines.

Attendants will be maintained in each court, who will receive the wheels, check them and then place them in racks, where they will be kept until the return of the owners.

No person without a bicycle will be permitted to enter the wheel courts. The charge for the service will be very light.

Transportation Facilities.

W. H. Holcomb, General Manager of transportation, has just completed a final estimate of the carrying capacity of the lines that will control the Jackson Park traffic. He has found that not more than 100,000 persons can be handled in one hour, but even that will make any serious blockade or inconvenience impossible. This estimate may be increased a little during good weather, when an extra force of excursion boats may be brought into service on the lake. The following is the estimate sent by Mr. Holcomb to the Council of Administration:

World's Fair Steamship Company—Three vessels, with a carrying capacity of 5000 each.
Illinois Central—Five tracks, each with a capacity of 6000 per hour.
Baltimore & Ohio—Capacity of 5000 per hour.
Chicago & South Side Rapid Transit (Alley L)—Capacity of 20,000 per hour.
Wabash Avenue Cable Line—Capacity of 15,000 per hour.
State Street Cable Line—Capacity of 15,000 per hour.

This gives a total of 100,000 per hour carrying capacity. Mr. Holcomb believes this to be sufficient to meet all demands unless some accident should occur; and, to prevent trouble, he is now giving his time to a plan for perfecting all terminal facilities. There are now being constructed within Jackson Park thirty-five terminal tracks, all of which will be constantly in use after May 1. The trains made up at the park will be the heaviest ever drawn, averaging fourteen cars each.

Old Locomotives Received.

There rolled into Jackson Park last week a quaint little locomotive 57 years old and with a history possessed by no

other engine in the country. This little old locomotive was the first one used on a railroad west of Chicago and was the first one to come into Chicago. Forty-four years ago it was shipped there by lake. At that time there was no railroad in Chicago running East. The Lake Shore, which was the first to reach the city, had not at that time completed its line. The locomotive was purchased for the Galena & Chicago Union Railway, which was constructing a line to Galena, and its first service was to haul rails and ties for the extension of the new line. It weighs, all told, but 8072 pounds and has only six wheels. There are but two drivers and these are connected directly with the piston rod. Its fittings are extremely simple. The locomotive is owned by the Chicago & Northwestern Railroad. It was built in Philadelphia by M. W. Baldwin in 1836. It was originally constructed for the Utica & Schenectady Railroad and subsequently sold to the Galena. It has no brakes of any sort and its whistle is of a diminutive character. It is the first locomotive to be installed in the Transportation Building. Two old locomotives have also been received from France. The names of the locomotives are the Samson, built in 1837, and the Albion, built in 1838. A passenger coach of great antiquity accompanied them. It is upholstered in white satin and is in a splendid state of preservation. The engines are queer pieces of mechanism, having perpendicular cylinders and connecting rods with the old hook action. They were built in England.

Wisconsin's Display of Minerals.

Among the State exhibits in the Mines and Mining Building Wisconsin promises to make a showing that will stand in the very front rank and attract universal admiration. Special effort is being put forth by the Badger Commonwealth in arranging its display of mineral and geological products, many of the most valuable specimens of which will enter into the construction of a magnificent pagoda 25 feet high, and occupying a floor space on one of the best blocks in the Mines Building 49 feet long by 45 feet wide.

This pagoda will consist of four monoliths resting on elaborately carved bases furnished by the Prentice Brown Stone Company. There will be two entrances of terra cotta surmounted by the coat of arms of the State. The railing extending around the four sides will be made of green jasper and fancy granites with wrought brass panels of clever design. The plans show that the pavilion in the center rests on four blocks of different colored granite, and the capitals of the columns which hold them will be liberally studded with amethysts and other brilliant stones. The fountains in the center of the pagoda will also be of amethyst, the whole scheme forming what promises to be one of the most attractive features in Chief Skiff's department of the great show. It is estimated that the entire display, as it stands when ready for public inspection, will represent an outlay in preparation of $20,000.

The pagoda will be filled with handsome showcases containing the best specimens of ores and minerals of all kinds that Wisconsin can produce. For instance, there will be one case holding $250,000 worth of pearls. It was designed by the Beatty Mfg. Company. The display will rest on a platform made of white and black marble tiling, the whole being surmounted by a beautifully-gilded dome, richly ornamented, thus giving the display a showy effect both from the galleries and distant sections of the building.

Fraser & Chalmers' Exhibit.

Fraser & Chalmers of Chicago are preparing a fine exhibit for the Mines Building. Having been located under the main gallery, the firm found it impossible to secure sufficient hight to put in a vertical engine that would have added largely to the attractiveness of the exhibit. This also prevented the introduction of a ten-stamp combination silver and gold mill, which, in operation, would have attracted probably as much attention as almost anything at the Fair. However, these drawbacks will not interfere with the company's arranging a very fine display of modern mining machinery.

In the array of what may be classed as most interesting devices shown will be water jacket smelting furnaces for smelting copper, silver, lead and tin, a concentrating machine, light and heavy crushing machines for grinding ore, sundry smelting devices, lead and silver smelting furnaces, copper furnaces, copper converters for Bessemerizing purposes, and all the apparatus that enters into the metallurgy of gold, silver, copper, tin and lead.

Besides these devices there will be a 20 x 40 Corliss engine adapted to the Riedler air compressor, a twin compound engine adapted to the Riedler pump, and a standard hoisting engine. The triple expansive vertical condensing winding engine, which is 23 feet high, cannot be set up in the center of the exhibit. This engine is a reproduction of four others made for the De Beers diamond mines of Kimberley, South Africa. It will probably be set up in Machinery Hall. Fraser & Chalmers will also have an engine of 1000 horse power in the power plant of that department.

Spain at the Exposition.

Advices have been received from Spain that January 28 the first consignment of exhibits was sent to Chicago, consisting of 500 cases of various objects. One of the most interesting exhibits will be that of the War Department, which intends to send to Chicago a rare collection of ancient artillery of the kind used in the days of Columbus. There will be lombards and falconets, cannons and mortars, shells and projectiles of every description, all of Spanish manufacture; and in addition there will be an exhibit of modern war materials, together with books and pictures of all the gun factories and war materials of Spain. In the city of Tarrasa great activity has already been displayed, and a large exhibit of manufactures of that town is being collected for the exposition.

The Fair Will be Closed on Sundays.

Exposition officials were not wholly surprised, but were greatly disappointed by the action of Congressman Durborow's committee in declining to report the Houk bill. A majority of the directors feel convinced that the Sunday opening movement is dead, and little effort will be made to do anything more with Congress in that matter. F. W. Peck, chairman of the Finance Committee, is hopeful that there will be a special session of Congress and that there may be a fighting chance then to secure favorable legislation. But in his hope he is not generally supported by his fellow directors.

Director General Davis declines to discuss the question. He said he was a national officer and bound to obey the dictates of Congress. He would say nothing further than if the law were not repealed the fair would be closed on Sundays so tight that nobody could get into it. It is not believed that the directory will take any steps toward undoing the act of the last session of Congress.

A Deserved Promotion.

Frederick Sargent, mechanical and electrical engineer of the exposition, was promoted to a position in which he will have several assistants to perform under him the work of the department. The work was divided into two divisions. The mechanical engineering section will be in charge of Robert Pierce. Mr. Sargent will remain at the head of the two divisions and direct the work of both.

J. A. Fay & Egan Company.

The consolidation of the firms of J. A. Fay & Co. and the Egan Company, both of Cincinnati, Ohio, has been announced, and the officers of the new J. A. Fay & Egan Company will take charge about March 1. The successful bringing together of these two rival concerns may be regarded as an important move, since it makes the new company the largest manufacturers of wood-working machinery in the country. The two plants occupy squares on the opposite sides of the street, and are therefore especially well fitted for being united under one management.

The directors of the new company will be Thomas P. Egan, Frederick Danner, W. H. Doane, D. L. Lyon, David Jones, W. P. Anderson, Joseph Rawson, S. P. Egan and Edwin Ruthven. Thomas P. Egan will be president, Frederick Danner vice-president, S. P. Egan superintendent and Edwin Ruthven secretary. These four officers are of the Egan Company.

The Egan Company date from 1873, when Thomas Egan, with two partners, started in a small way. A stock company was formed in 1880, and the business proved so successful under able management that additional factories were built, until now the plant covers an entire block, and employs 800 men.

The original J. A. Fay & Co. were established in Keene, N. H., about 1835. In 1850 a branch was established in Cincinnati to meet the demands of the Western trade and to save the expense of transportation. In 1860 not more than 15 men were employed in the works, while now there are over 500. This plant also covers a square block of ground.

The consolidation will not affect the working of the two establishments in the least, and the amount of product and the number of men employed will not be reduced. They will be in position to fit out a wood working establishment entire with machinery of their own manufacture.

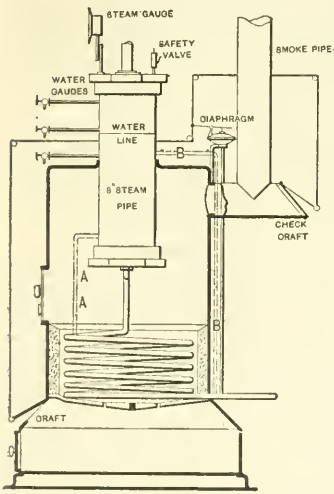
The new building which is to accommodate the Department of Mechanical Engineering of the Pennsylvania State College, in Centre County, Pa., was formally dedicated on February 22. The building, which has been erected by the Commonwealth of Pennsylvania for the purposes of industrial education, at a cost of about $100,000, is stated by the *Williamsport Times* to be a very handsome structure, of good design and well adapted for the purpose to which it will be devoted. It is of ample proportions, covering an area 206 x 208 feet square, is three stories high, and contains in all 57 rooms, with all the most improved facilities for heating, lighting and ventilation, as well as a complete equipment of tools and apparatus for the instruction and practice of the students. The educational departments include mechanical and sanitary engineering, hydraulics, machine work of all kinds, smiths' work in a shop with 20 forges and anvils, wood working, pattern making, pipe cutting, steam fitting, &c. A museum of mechanical devices, model rooms, laboratories, libraries, drawing rooms, and a number of classrooms, together with offices for the professors attached to the department, are provided in the building. Three hundred students can be accommodated in the different undergraduate and post graduate engineering courses, and free scholarships have been provided by the trustees, which will place the facilities of the new college department within reach of all.

STEAM AND HOT-WATER.

A Home-Made Heating Boiler.

From C. W., *East Pepperell, Mass.*—I want to build a small steam heating apparatus to heat about 150 feet of radiation. Do you think that the boiler shown in the inclosed sketch will be satisfactory? The coil is 1¼ inch pipe and the boiler is 8-foot steam pipe.

Answer.—We reproduce our correspondent's sketch. To carry 150 square feet of surface it will be necessary to have a boiler capable of developing about 2 horse-power, or at any rate not less than 1½ horse-power. The surface exposed to the direct action of the fire should be about 10 square feet, the usual proportion of fire and flue-heating surfaces being 1 of heating surface to every 5 to 8 square feet of surface in radiators. The coil as shown connected to the 8 inch diameter drum will not work as satisfactorily as if provision were made for circulation between



A Home-Made Heating Boiler.

coil and drum in some such manner as shown by dotted lines A A, B B. Such a change will tend to make the water line more steady than when arranged as shown by our correspondent.

Heating Room to 175° F.

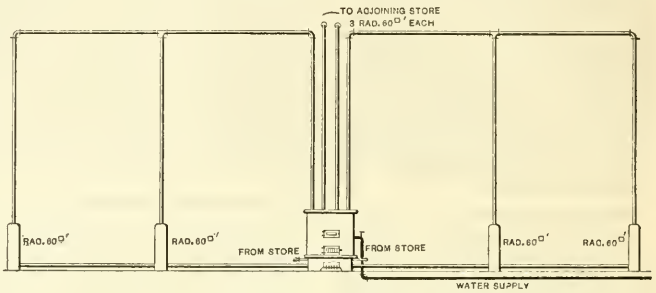
From W. J. Y., *Winston, N. C.*—Will you inform me how much 1-inch pipe it will require to heat a room 22 x 15 x 11 feet to 175° F.?

Answer.—We wrote to this correspondent for additional particulars, but those furnished by him in reply are yet too meager to enable us to answer the query definitely without making some assumptions. The room, he states, is located in the northeast corner of the fourth story of a tobacco warehouse and has four windows, 7 x 3½ feet in dimensions. The steam for heating is to be carried through a pipe 125 feet long. We infer, also, that the room is to be used as a dry room, and, doubtless, some ventilation will be required. But, this point being left indeterminate, it cannot be considered in our answer. On the assumptions that the inclosure will be made in all its parts as resistant to the passage of heat as a brick wall 1 foot thick, lined with tin and having a dead-air space between the tin lining and the wall, would be, that the windows will be double, and not taking into account any air admitted for ventilation, also assuming the lowest exterior temperature to be for all sides of the room an average of 30° F., 1237 feet run of 1-inch pipe will be required, with steam carried at 60 pounds pressure, to meet the extreme conditions. The bulk of this pipe should be arranged in coils of vertical pipes along the middle of the room, leaving space to pass by them at the ends, and the main supply pipe ought not to be less than 2-inch. The arrangement could probably be designed to secure a gravity return of the condensed water to the boiler; but if this be not practicable a return trap or a condensed-water tank and a small feed pump may be used. The supply pipe should be covered with good insulating material, so as to bring the steam to the coils as dry as possible. If ventilation is required more pipe will be needed in the coils. Such a job as this ought to be erected under the advice of a competent engineer if the best results are to be obtained.

THE TRADE will regret to learn that W. C. Mowry, the well-known boiler manufacturer of Norwich, Conn., is confined to the house by illness. It is hoped, however, that the genial colonel will be about soon in his accustomed good health.

A Novel Musical Instrument.

From EDWIN C. MASON, *Madison, Wis*—I have in my store a system of hot-water heating of which the diagram sent herewith will give you an idea. Wishing to show this heater to my customers, I put it on the main floor in my show room and piped it in the way indicated in the diagram. The radiators are on a level with the return pipes, and, in order to secure circulation, I adopted the syphon system of running flow pipes nearly to the ceiling.



A Novel Musical Instrument.

In addition to heating my store, I heat an adjoining store of nearly the same size by running pipes through the wall.

The peculiar feature of the system is this: Under certain conditions of the fire, and when the water is just about at the boiling point, a series of musical sounds are produced, varying in pitch with the intensity of the fire, and also changing tone when the water in the system is increased or diminished in greater or less degree. I also find that I can change the note by opening the feed door, the check drafts or the slide draft on the ash-pit door. By a little practice I can produce something very much like the musical scale. The notes at times are very deep and sonorous and excite the admiration of all who listen to them. I have not yet succeeded in playing a tune, but shall endeavor, when I have a little leisure, to do the calliope act for the benefit of my friends and customers. The cause of all this is probably in the unusual tension in which the whole system is placed, there being no passages of pipes through the wall of any account, and the pipes not being supported in any place excepting at the heater and at the radiators.

It is something quite unusual, I think, to find a heating apparatus which also serves the purpose of an orchestra, and I thought perhaps it might interest your readers to know of this very peculiar affair.

E. C. MASON, Madison, Wis., representing the Sunray hot-water and combination hot-water and warm air heaters, also the Star heater for hot water and warm air, manufactured by the J. L. Mott Iron Works, New York and Chicago, has placed quite a number of these heaters in the residences of prominent parties in Madison and vicinity. Mr. Mason's re-

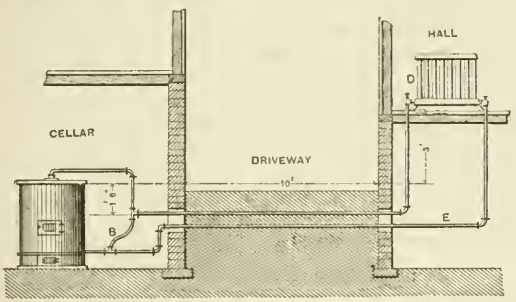
ports regarding these heaters are very flat tering. One of his customers wrote him during the late cold weather, "Cold, cold everywhere, but where the Mott Star combination heater holds sway there summer reigns."

Dropping a Flow Pipe.

From W. M., *Gloucester, Mass.*—Please inform me how a hot-water flow pipe can be dropped between heater and radiator with an open-tank system and give satisfaction. I have a hall to heat 10 feet from the house in which the heater is located and must cross a driveway 18 inches lower than the top of the heater. I cannot lower the heater and there is no way of running over the head of the driveway. The radiator in the hall will be 3 feet above the top of the heater. If I drip ell at the point B will it start the circulation?

Answer.—In answering our correspondent's interesting query we have reproduced his sketch, Fig. 1, and added two sketches, Figs. 2 and 3, in order to be as explicit as possible in our reply. We assume that the boiler to which it is desired to connect radiator in hall is also used for heating the house in which it is located. In Fig. 1 the circulating pipe is too near the boiler and might tend to raise the temperature of pipe A, and pipe to return will be removed.

Fig. 3 illustrates the indirect method of circulation. The water from the boiler in this case passes to the tank first and thence down to flow pipe to radiator, during which passage it loses a certain amount of its heat. The circulating pipe B in this case will be found very useful. In either case, Figs. 2 or 3, the circulating pipe B may be the same size as the flow and return pipes to radiator. As shown in Fig. 3 by F and G, separate connections are also taken from boiler to each radiator.



Dropping a Flow Pipe.—Fig. 1.—Plan Proposed by Correspondent.

the return too quickly, thus impeding the natural circulation to D and E. Fig. 2 shows the manner of connecting pipes which may be adopted with some boilers, and

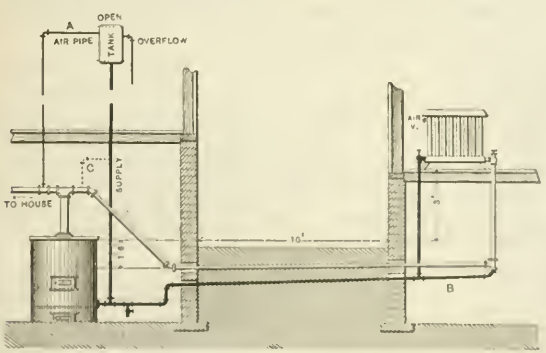


Fig. 2.—Showing Direct Circulation Between Boiler and Radiator.

by which direct circulation is attained. The circulating pipe B may be omitted if desired. If only the one radiator is connected to boilers the air pipe, C dotted lines, Fig. 2, can be used in place of air

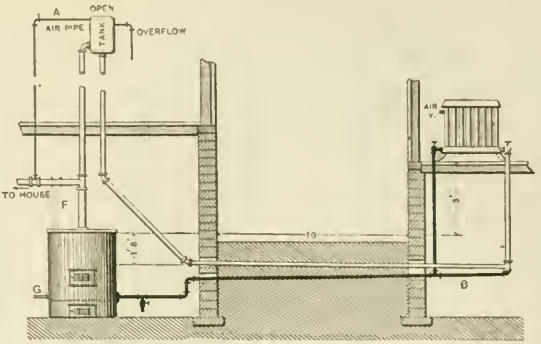

Fig. 3.—Showing Indirect Circulation Between Boiler and Radiator.

For the convenience of the trade the American Boiler Company of Chicago have decided to change the name of some of the boilers made by them. The Perfect sectional steam boiler will hereafter be known as the American. Their new circular sectional boiler will be designated as the Modern, while the small stove hot water heater, designed for use in baptisteries, laundries, baths, &c., will be known as the Little Giant. The name Perfect will apply only to their sectional hot-water heater.

National Association of Master Fitters.

At the monthly banquet of the Chicago Local Association of Master Steam and Hot Water Fitters held February 8, President P. S. Hudson of the National Association delivered an address setting forth the advantages of the central organization and the dependence upon it of the local associations and isolated members.

In the early part of his address he referred to the invitation he had received as president of the National Association to point out the necessity of such an organization. In introducing the subject he quotes from the second annual report of the national secretary in 1890 showing the increased power of the organization when united action can be taken by all its members in all parts of the country. Mr. Hudson continued:

"I have already said enough to show why there should be a National Association. There are many good arguments I shall be unable to call to mind. However, I am unwilling to pass by the social feature, the acquaintanceship that has been made between men of different cities, the general development and growth of the business vouchsafed at each of our conventions. All this is worth the expense of a national membership. There is new light and instruction given at every such meeting, which, even though a man is not present, is reflected to him through his comrades who do attend, as was attested at our last convention by one of our members in a talk on the floor in illustrating the benefit the National Association was to him through his improvement by mingling with the craft at such times, claiming that the new ideas he carried home with him were of much greater value than the cost of his annual dues. The time has passed when each individual firm is trying to draw the veil over the discoveries which experience has proven beneficial; they are passing their new achievements out to one another now, and this, too, is worth the cost of the National Association to each of its members.

"Again, at our last convention, a new clause was ingrafted in our constitution

which will be found there (numbered 18) requiring members who go from one city to another seeking contracts to notify resident local or national members of their intentions. This one clause is well worth the cost of the National Association, as there have already been several illustrations of its usefulness.

"Again, the uniform manner in which we are fighting the Osborne patent cases is worth the price of the association to us, as they are apparently halting in consternation at our combined strength.

"Then, again, we should have a National Association as a guard against the unknown or unexpected with which we are likely to be overtaken at any moment in the face of the present progress and contention in business affairs; this, that we may be prepared to arise and assert our rights at the shortest possible notice and fight in a united manner against any unreasonable and inconsistent obstacles that may be thrown in our way, or any attacks that are unprincipled and damaging in their effects."

Following this is a long quotation from the *Master Steam Fitter*, together with a letter prepared by Secretary Reynolds. We print below the close of President Hudson's address:

"While upon this subject I will add one word with reference to men who have not, and do not join our National Association, and say to you that their remaining out partakes of the spirit of our colonial farmers at the time of the Revolutionary War, when they hauled and delivered their products to the British army at the very moment that Washington and his soldiers were freezing and starving at Valley Forge. They were so enamored of the penny in sight that they were willing to feed the element that was striving to hold them as subjects and ignore those who were suffering with cold and hunger and offering their lives to gain for them an independence.

"I claim that the men who remain out of our National Association are in a like manner fighting those who are struggling for their interests.

"The attitude I have take in this emergency is such as those whom I represent have a clear right to expect from any and all who have accepted an office at their hands. The interest with which I have in my feeble way endeavored to touch this question is deep seated, and did it not come from the heart I would feel it my duty to withdraw and make room for some one who would contribute more soul to the work, but you will permit me to add that what I have said would receive from me just as strong an indorsement were I not an officer in the association, for surely if I were to feel less or do less I would not be truly serving my own best business interests.

"In summing our interests up I will say to you that I hope to live to see the day when objectors, scoffers and defamers of our National Association will be of the past utterly, and I ask you now if pride alone in the simple fact of the national headquarters being located in this city for the last year, where we are soon to entertain our craft from all over the United States, should not cause a unanimous vote in shelving any proposition that is disposed to strike out the clause in our constitution and by-laws requiring members of our local to become members of our National Association, and I ask you as men doubly interested in the success of the business in which we are engaged to cast your votes, each and every one of you, that the clause shall stand as it now reads."

The question of changing the by laws having been put to the meeting, the amendment referred to in the last paragraph of President Hudson's address was lost by a unanimous vote.

Some Heating Queries.

From J. M. G., *Peoria, Ill.*—Please answer the following questions through *The Metal Worker:* How many square feet of radiating surface will a 1-inch pipe supply, the steam being at 40, 60 and 80 pounds pressure? How many feet of outside wall (frame building, hollow walls) are equal to 1 square foot of glass, and how much does glass require in radiators? How much more surface does a frame building require than a brick building? Is the piping correct in the sketch of building sent herewith? The main supply is carried to the front of the building before entering the coils. A friend of mine says it should have been the other way—that is, the steam should enter first and the water be returned from the far end, his reason being less cost. Which is the more economical and better? Would it have any effect on a gravity apparatus?

Answer.—In reply to our correspondent's first query as to the quantity of radiating surface a 1-inch pipe will supply at 40 pounds, 60 pounds and 80 pounds pressure, we will base our answer on a formula published by F. Schumann. It is as follows: Radiating surface in square feet equals a constant 184 divided by the square root of the length of the supply pipe, multiplied by the square of the diameter of the pipe, and this product multiplied by the square root of the pressure multiplied by the diameter of the pipe, divided by the weight of a cubic foot of steam at the given pressure, taking in each case the length of supply pipe at 100 feet.

First example, 40 pounds pressure:

$$\frac{184}{\sqrt{100 \text{ feet}}} = 18.4 \times 1 \text{ dia. of pipe squared}$$

$$= 18.4.$$

$$\sqrt{\frac{40 \text{ pounds} \times 1 \text{ dia. of pipe}}{0.13046 \text{ (weight of steam at 40 pounds)}}} =$$

17.49.

$18.4 \times 17.49 = 321$ square feet of surface in radiators, which a 1-inch pipe will supply at 40 pounds pressure.

Second example, 60 pounds pressure:

$$\frac{184}{\sqrt{100 \text{ feet}}} = 18.4 \times 1 \text{ dia. of pipe squared}$$

$$= 18.4.$$

$$\sqrt{\frac{60 \text{ pounds} \times 1 \text{ dia. of pipe}}{0.17493 \text{ (weight of steam at 60 pounds)}}} =$$

18.49.

$18.4 \times 18.49 = 340$ square feet of surface in radiators, which a 1-inch pipe will supply at 60 pounds pressure.

Third example, 80 pounds pressure:

$$\frac{184}{\sqrt{100 \text{ feet}}} = 18.4 \text{ 1 diam. of pipe squared}$$

$$= 18.4.$$

$$\sqrt{\frac{80 \text{ pounds} \times 1 \text{ dia. of pipe}}{0.21874 \text{ (weight of steam at 80 pounds)}}} =$$

19.1.

$18.4 \times 19.1 = 351$ square feet of surface in radiators, which 1-inch pipe will supply at 80 pounds pressure.

From 5 to 10 square feet of outside wall of frame building may be taken as equal to 1 square foot of glass.

One square foot of glass is estimated to lose 1.57 units of heat per hour for a difference of 1° between the external and internal temperature. The loss of heat from 1 square foot of surface in radiator in room is, approximately, about 2 units of heat per hour for each degree of difference of temperature between the surrounding air and that of the surface of the radiator, which is usually taken as the same temperature as that of the steam within the radiator. The temperature of steam at 40 pounds pressure is 286°, from which deduct 70°, temperature of room, and the remainder equals 216°, which, multiplied by 2 units of heat, the loss per degree of difference, equals 432 units of heat given off per square foot of surface in radiator. Taking the outside temperature at zero, 70 multiplied by 1.57 equals 109.9 units of heat lost per hour through 1 square foot of glass. Then $\frac{432}{109.9} = 3.9$, the square feet of glass which absorb or lose the same quantity of heat as given off by 1 square foot of surface in radiators.

We did not consider it necessary to reproduce our correspondent's sketch, as the letter sufficiently explains the arrangement about which advice is desired. It is better to carry the main supply pipe to the front of the building. This arrangement is to be preferred, with either a mechanical means of returning the water of condensation to the boiler or when it is returned by gravity. The extra cost is the difference between the cost of the supply pipe and the return pipes in position.

When windows, doors, &c., are equally well fitted, frame buildings will approximately take from 10 to 15 per cent. more radiating surface. Some well-built frame buildings are as easily heated as brick buildings.

Stopping Leaks in Steam Pipes.

From E. E. P., *Woburn, Mass.*—I would like to ask "G. H. A." of Jersey City, N. J., who, in *The Metal Worker* of February 4, recommends a mixture of equal parts of sulphur and sal-ammoniac as a preventive of leaky steam or water pipes, what is the best way to use the mixture?

HEATING NOTES.

At a meeting of the Executive Committee of the Master Steam and Hot Water Fitters' Association of the United States, held on the 28th ult., it was decided that the next Annual Convention of the association should be held in Chicago, beginning Tuesday, June 6, at 10 o'clock a.m. The duration of the convention will depend upon the wishes of the members attending.

The Illinois Heating Company have lately been organized in Chicago, with a capital stock of $10,000. The officers and incorporators of the new company are: Frank Wheeler, president; C. B. Thompson, secretary; C. C. Finkler, treasurer. Mr. Wheeler has been the Chicago manager during the past four years of the Pierce, Butler & Pierce Mfg. Company. Mr. Thompson during the same period has managed the Chicago office of the National Hot Water Heater Company, and Mr. Finkler has been Chicago manager of the Detroit Heating & Lighting Company of Detroit. These gentlemen have

THE MANUFACTURES BUILDING OF THE WORLD'S FAIR.

been closely identified with some of the best work in Chicago, both in steam and water heating, and will make a specialty of fine residence work, giving it their personal supervision. They are prepared to figure on any reputable boiler in the market. The new company have secured commodious quarters at 88 Lake street, which are being fitted up for office, salesroom and shop.

M. L. Foote, formerly in the employ of the Pierce, Butler & Pierce Mfg. Com pany, has associated himself with the American Boiler Company of Chicago, and will be located permanently in St. Louis, where he will devote his attention to the sale of the various boilers made by that company.

The Kewanee Boiler Company, Kewanee, Ill., manufacturers of Haxtun magazine boilers for steam and hot water, also tubular and portable house-heating boilers, have removed their Chicago office from 36 Dearborn street to 96 Lake street.

Wm. H. Peterson, who for a number of years was connected with the steam fitting concern of John S. Trachsall & Son, Arch street, Philadelphia, has entered the employ of the American Boiler Company, Chicago, and will be the resident representative of that concern for Philadelphia and vicinity.

The Gurney Hot-Water Heater Company, Boston, Mass., inform us that they recently received another gold medal diploma "in confirmation of the gold medal awarded them by the Massachusetts Charitable Mechanics' Association at Boston in the year 1887." We understand that the company now possess the following medals and diplomas: From the American Institute, New York, 1887, "Medal of Excellence," in 1888 a "Special Medal," and in 1889 a "Medal of Superiority." From the Massachusetts Charitable Mechanics' Association a gold medal in 1887, special gold medal diploma, November, 1890, and special gold medal diploma, November, 1892. These diplomas are in confirmation of the gold medal awarded in 1887. The silver medal awarded in 1892 was on their new 300 Series and Double Crown hot water heaters.

Frank Shay, formerly manager of the New York branch of the Detroit Heating & Lighting Company, will represent the Capitol Heater Company in New York, Eastern Pennsylvania, New Jersey, &c.

F. X. Brunell, Worcester Mass., is the patentee of a steam generator or heater, the furnace of which is composed of a series of helically coiled tubes, the ends extending backward and connected with an upright trunk or standpipe outside the circles of the coils.

The Capitol Heater Company, Detroit, Mich., favor us with another of their postal travelers, which are cards containing advertising matter relating to their manufactures. The last one received carries on the front a picture of a salesman opening a satchel and with it the statement that he has a new heater in his grip this winter. Later on it makes reference to the Bolton boiler and its points of advantage. On the back of the card are letters from several sources referring to the excellent results given by the Bolton water heater.

We learn from Foskett & Bishop, New Haven, Conn., that they have established wholesale agencies at Chicago and Cleveland for supplying the Western trade with their improved G. & J. R. Bolton heaters. We understand that the number of inquiries reaching them from the West made this step necessary. We further learn from this concern that J. W. Runner, who for the last three years has travelled for the Detroit Heating & Lighting Company in Central and Western New York State, is now traveling that district for Foskett & Bishop. The interests of this firm in Michigan will be looked after in Detroit by George Bolton.

Foskett & Bishop, New Haven, Conn., with New York office at 114 Liberty street, issue an illustrated catalogue and price-list of the G. & J. R. Bolton hot-water heater of their manufacture. The pamphlet, of oblong shape, contains various illustrations of this apparatus, showing broken views as well as general views and illustrations of the heater with the casings removed. All the features of the apparatus are referred to in the description and the advantages are pointed out. A table gives complete dimensions and other particulars, together with prices. The catalogue also notices Foskett & Bishop's improved steam traps. At the end of the circular are a number of testimonial letters and references.

The Sheet-Metal Gauge Bill.

We have received from Oberlin Smith of Bridgeton, N. J., the following letter:

It is earnestly to be hoped that Congress will not pass the Sheet-Metal Gauge bill, as described in your issue of February 11, without at least making in it important modifications, as the absurdities apparent upon the face of it, when glancing at the table you quote, are sufficient to condemn it in the eyes of any systematic engineer. Among these are the ciphers (in one case extending up to seven) at the beginning of the series of size numbers, instead of beginning with unity. Also the following of the old system of putting small numbers for the larger thicknesses, and *vice versa*. Also the actual sizes of the gauge dimensions themselves, which run in very curious fractions that are not measurable by ordinary tools. The only good and systematic thing about this proposed system is that the respective gradations agree with certain definite numbers of ounces per square foot of iron or steel, these two happening to be of about the same specific gravity. This very fact, however, makes the gauge unfit for measuring, by the same system, tinned or galvanized sheet iron, brass, copper, zinc, aluminum, silver, gold and other metals, as well as paper, leather, &c.; and it also makes it unsuitable for a wire gauge for all kinds of material, including iron. Exactly how the interesting groups of seven, and six, and five ciphers above mentioned are to be pronounced in speaking, we have not been informed.

Just why we should have saddled upon us a law of this kind, after which we shall have to use various other gauges for wire, screws, rivets and nearly all the sheet metals, passeth ordinary comprehension. It is certainly to be hoped that the bill in its present shape will be defeated, and that some forthcoming action by the American Society of Mechanical Engineers, and perhaps by other scientific societies, will be productive of good in leading the way toward a sensible gauge of some kind. Such, for instance, might be one founded upon the actual fractions of an inch involved, these preferably being expressed in thousandths. This perfectly simple and natural method was proposed by me at the Erie meeting of the American Society of Mechanical Engineers, and has more than once been promulgated in your columns since that time. All there is to do is to make gauges to suit different trades with such notches in them as may respectively suit each case in question. These notches have only to be numbered by the number of thousandths of an inch that measure them, and everything will agree—even though some gauges may have entirely different sequences of numbers from others.

The Manufactures Building.

(*With Supplement.*)

An illustration is herewith given of the great Manufactures Building of the World's Fair as it now appears. The view has been taken at the southwest corner. The sheet of water shown is a portion of the lagoon, which communicates with Lake Michigan at the right and extends to the left past the Manufactures Building and thence through the grounds under a succession of ornamental bridges. This is the body of water which will be navigated during the exposition by steam and electric launches, gondolas, &c. The Manufactures Building was completed some time since, and a large force of workmen are now engaged in the erection of booths and pavilions for the numerous exhibitors. Exaggerated accounts have recently been published of damage to the roof of this building by accumulations of snow during the extraordinary winter, which has been especially severe in the Northwest. The frame work of the roof has not been injured in the least, as it is so strong that nothing short of an earthquake could affect it. Wet snow sliding from the sides of the great central span fell on the skylights at its base and crushed a few of them in, entailing some work in replacing or repairing them, which will not cost more than a few thousand dollars, and proving more of an annoyance than an expense. The illustration will enable this explanation to be intelligently grasped. This building is the mammoth structure of the exposition, measuring 1687 x 787 feet, and covering nearly 31 acres is the largest exposition building ever constructed.

Within the building a gallery 50 feet wide extends around all four sides, and projecting from this are 86 smaller galleries, 12 feet wide, from which visitors may survey the vast array of exhibits and the busy scene below. The galleries are approached upon the main floor by 30 great staircases, the flights of which are 12 feet wide each. Columbia avenue, 50 feet wide, extends through the mammoth building longitudinally, and an avenue of like width crosses it at right angles at the center. The main roof is of iron and glass and arches an area 385 x 1400 feet, and has its ridge 150 feet from the ground. The building, including its galleries, has about 40 acres of floor space.

The Manufactures and Liberal Arts Building is in the Corinthian style of architecture, and in point of being severely classic excels nearly all of the other edifices. The long array of columns and arches which its façades present is relieved from monotony by very elaborate ornamentation. In this ornamentation female figures, symbolical of the various arts and sciences, play a conspicuous and very attractive part.

The exterior of the building is covered with "staff," which is treated to represent marble. The huge fluted columns and the immense arches are apparently of this beautiful material.

There are four great entrances, one in the center of each façade. These are designed in the manner of triumphal arches, the central archway of each being 40 feet wide and 80 feet high. Surmounting these portals is the great attic story ornamented with sculptured eagles 18 feet high, and on each side above the side arches are great panels with inscriptions, and the spandrils are filled with sculptured figures in bas-relief. At each corner of the main building are pavilions forming great arched entrances, which are designed in harmony with the great portals.

TIN PLATES.

American Tin-Plate Production.

Ira Ayer, special agent of the Treasury Department for the collection of statistics of the production of tin and terné plates in the United States, has issued the following report for the quarter ending December 31, 1892:

I have the honor to report that during the quarter ended December 31, 1892, 32 firms produced 19,756,491 pounds of tin and terne plates proper. The same number of firms produced during the previous quarter 10,952,725 pounds. Of the production of the past quarter 6,138,739 pounds, or a little less than one-third of the whole, were bright tin plates, of which 5,274,434 pounds, or about 86 per cent., consisted of the class of plates weighing lighter than 63 pounds per 100 square feet; 13,617,752 pounds were terne plates, of which 12,684,646 pounds, or more than 93 per cent., belonged to the lighter class; of the entire product nearly 91 per cent. consisted of the lighter class of plates.

The amount of American sheet iron and steel made into articles and wares tinned or terne during the quarter, as shown by the sworn statements of manufacturers received to date, was 2,245,506 pounds, and for the previous quarter 898,233 pounds. This makes the total production for the last quarter, within the meaning of the law, 22,001,997 pounds, against 11,850,958 pounds produced during the quarter ended September 30, 1892, and shows a total production for the six months ended December 31, 1892, including the products from American sheet iron and steel tinned of 33,852,955 pounds.

The production of tin and terne plates proper during the first six months of the present fiscal year was 30,709,216 pounds, against 2,236,743 pounds produced during the corresponding period of the previous year, the ratio of increase having been nearly as 1 to 14. The production of the last fiscal year was 13,646,719 pounds, which is considerably less than one-half the production during the first six months of the present year.

American Black Plates.

Of the production of 19,756,491 pounds of tin and terne plates proper during the past quarter, 8,043,449 pounds, or more than 40 per cent., were made from American black plates, against 5,920,082 pounds used during the previous quarter. The consumption of American plates in the production of tin and terne plates proper during the first six months of the present fiscal year was 13,963,531 pounds, or 316,812 pounds more than the total product of tin and terne plates proper during the first year that the law became operative. The consumption of American plates for the same purpose during the first six months of the fiscal year ending June 30, 1892, was 1,986,208 pounds, the ratio of increase for the corresponding period of the present fiscal year having been as 1 to 7. The total consumption of American plates, including articles made from sheet iron or steel and tinned, during the first six months of the last fiscal year was 4,474,755 pounds, and for the first six months of the present fiscal year 17,107,270 pounds.

Of the 32 firms who submitted their sworn returns for the quarter nine made and used their own black plates exclusively, four others used only American plates, nine used both American and foreign plates and ten used only foreign plates. The American plates are generally preferred by manufacturers to the foreign.

The foregoing figures are taken from the sworn statements of manufacturers, the details of which have been tabulated in Exhibit 1, appended hereto. A summary of production for the four quarters of the last fiscal year and for the first two quarters of the present year is also appended (Exhibit 2). To these exhibits attention is respectfully invited.

Imports and Exports.

Full returns from the importing and exporting ports of the country show that the imports of tin and terne plates, and the exports of the same in the form of manufactured articles, with benefit of drawback, were as follows:

	Lighter than 63 pounds per 100 square feet.	63 pounds per 100 square feet and heavier.
IMPORTS.	Pounds.	Pounds.
Tin plates	332,328,123	14,519,549
Terne plates	42,368,883	1,334,147
Totals	374,697,006	15,853,696
EXPORTS.		
Tin plates	136,740,638	480,847
Terne plates	32,552	155
Totals	136,773,190	481,002

From the foregoing it is seen that of the class of plates weighing lighter than 63 pounds per 100 square feet there were imported

	Pounds.
During the fiscal year ended June 30, 1892	374,697,006
And of the same class of plates there were exported	136,773,190
Making the net importations for the year	237,923,816
One-third of which is	79,307,939

Under existing provisions of law American manufacturers must produce, during one of the six fiscal years ending June 30, 1897, one-third of the net importations of one of the said years. If it be assumed that the net importations will not be less during any one of the remaining years specified, the amount of the lighter class of plates which must be produced by American manufacturers during one of the six years in question may be positively stated at 79,307,939 pounds.

As shown in former reports, it is probable that this amount will be equaled during the present fiscal year.

Present State of the Industry.

It has been seen that during each of the first two quarters of the present fiscal year 32 firms were engaged in the production of tin and terne plates proper, and made their sworn returns to the Government. Three firms were added to the list of producers during the last quarter, viz, the Blairsville Rolling Mill & Tin Plate Company of Blairsville, Pa.; the Morewood Tin Plate Mfg. Company of Elizabethport, N. J., and the Phillips Tin Plate Company of Philadelphia, Pa.

Two firms which made returns for the quarter ended September 30, 1892, were not producing during the past quarter, owing to temporary causes. The works of the Anderson Tin Plate Company of Anderson, Ind., were destroyed by fire and will probably not be rebuilt.

The Baltimore Steel, Iron & Tin Plate Company of Baltimore, Md., commenced working three tin sets about January 1, 1893, and state that they will soon have two additional sets in operation.

The Britton Rolling Mill Company of Cleveland, Ohio, inform me that they have most of the machinery on hand for their tin-plate department, but add that it is doubtful if they will proceed further until something definite is known relative to the action of Congress as affecting these interests.

The Canonsburg Iron & Steel Company of Canonsburg, Pa., have added two tin mills to their plant during the past year, and claim that they have a present capacity for stamping and black plates of about 6000 tons per year. Probably not more than one-fourth of this, they state, will be used as ordinary black commercial plates for tinning. A portion of the remainder is used in the manufacture of stamped ware, much of which is tinned. Some is used for polished work and for a variety of purposes, and does not require to be tinned, although the finish is said to be the same as for tin plates.

The Corning Steel Company of Chicago, Ill., write that the demand is so great for common black sheets that they have not attempted to make any regular black plates, preferring to keep their mill, for the present at least, on the common material. This firm have therefore been dropped from the list of manufacturers.

The Cumberland Steel & Tin Plate Company of Cumberland, Md., report that they started their works January 10, 1893, and have at present an output of 6 tons of black plate daily, the principal gauges being 28 and 30. Their expectation is that before July 1 next the capacity will be increased to 20 tons daily. The present output, they state, is sold to tinning houses in Pittsburgh and Philadelphia, and add that the entire product will be used for tin and terne plates.

The Morewood Company, located at Gas City, Ind., state that they have already completed four large iron buildings and have other buildings in course of construction, all of which are intended for tin plate manufactures.

The Falcon Iron & Nail Company of Niles, Ohio, state that they have met with unlooked for delays in securing the structural iron for their buildings, which should have been erected as early as December 1, 1892. The machinery is all on the ground, and the most of it set in place. They now expect to have two tin mills in operation by April 1, and estimate their output at 400 tons of tin plate per month. They will roll the sheets for tinning from the steel billet. Their machinery is built for four mills. They represent that they will at first sell their black plate product to parties who are engaged in tinning, but will commence work in the spring on their tinning department. The company propose to build a first-class plant throughout.

The firm of Hughes & Patterson, owners of the Delaware Rolling Mill of Philadelphia, Pa., have begun the erection of substantial buildings for the production of tin plates, but state that it will be some months before they will be in a condition to begin the actual manufacture.

The Indiana Tin Plate Mfg. Company of Atlanta, Ind., state that the hard winter

has considerably checked the progress of their buildings. They now hope to be in operation by March 1. They add that their present obligations are to erect a plant of two rolling mills, with the necessary finishing department, at a cost of from $80,000 to $100,000.

As neither the International Tin Plate & Refining Company of Chicago, Ill., nor the Joliet Tin Plate Company of Joliet, Ill., report any progress, their names have been stricken from the list of manufacturers.

The New Castle Steel & Tin Plate Company of New Castle, Pa., which is building a large and substantial plant, together with the continued erection of buildings and plants, as herein shown, serve to confirm the view expressed in a former report relative to the permanent establishment of this industry. In this connection the substantial increase in the production of American black plates is particularly noticeable.

In Exhibit 3, which gives a revised list of manufacturing firms December 31, 1892, I have adhered to estimates of production heretofore made. The estimated investment in buildings and plants, close of fiscal year ending June 30, 1893, as shown in my report of October 24, 1892, has been reduced.

Exhibit 1.—Abstract of Tin Plates and Terne Plates Produced in the United States during the Quarter ended December 31, 1892.

[The detailed entries in this abstract are taken from the sworn returns of manufacturers.]

Tin plates.				Terne plates.				Amount made from		
Lighter than 50 pounds per 100 square feet.	50 pounds per 100 square feet.	62½ pounds per 100 square feet.	63 pounds per 100 square feet and heavier. Exhibit 3.—Revised list of firms or companies engaged in tin and terne plate manufactures, December 31, 1892.

[*a*, Producing; *b*, building; *e*, enlarging; ***, making or preparing to make black plates.]

Note.—From the following list are omitted the names of all firms or companies who had not begun actual building operations December 31, 1892.

A. A. Thomson & Co., *a*, New York, N. Y.
Alliquippa Tin Plate Company, † *a*, Alliquippa, Pa.
American Stamping Company, *a*, Brooklyn, N. Y.
American Tin Plate Company. * *a*, Elwood, Ind.
American Tin Plate Machine & Mfg. Company, † *a e*, Philadelphia, Pa.
American Tin & Terne Plate Company, *a*, Philadelphia, Pa.
Apollo Iron & Steel Company, * *a*, Apollo, Pa.
Baltimore Steel, Iron & Tin Plate Company, *b*, Baltimore, Md.
Britton Rolling Mill Company, * *b*, Cleveland, Ohio.
Blairsville Rolling Mill & Tin Plate Company, * *a*, Blairsville, Pa.
Cincinnati Corrugating Company, *a*, Piqua, Ohio.
Cleveland Tin Plate Company, *a*, Cleveland, Ohio.
Coates & Co., * *a*, Baltimore, Md.
Columbia Tin Plate Company, *a*, Piqua, Ohio.
Cumberland Rolling Mill & Tin Plate Company, * *a e ‡*, Cumberland, Md.
E. Morewood & Co., * *b*, Gas City, Ind.
Falcon Iron & Nail Company, * *b*, Niles, Ohio.
Griffiths & Cadwallader, *a*, Pittsburgh, Pa.
Gummey, Spering & Co., *a*, Philadelphia, Pa.
Hughes & Patterson, * *b*, Philadelphia, Pa.
Indiana Tin Plate Mfg. Company, * *b*, Atlanta, Ind.
John Hamilton, *a*, Pittsburgh, Pa.
Kahn Bros., *a*, New York, N. Y.
Marshall Bros. & Co., * *a*, Philadelphia, Pa.
Matthai Ingram & Co., *a e*, Baltimore, Md.
McKinley Tin Plate Company, *a*, Wilkinsburg, Pa.
Merchant & Co., *a*, Philadelphia, Pa.
Morewood Tin Plate Mfg. Company, *a*, Elizabethport, N. J.
N. & G. Taylor Company, *a e*, Philadelphia, Pa.
Norton Bros., * *a e*, Chicago, Ill.
New Castle Tin Plate Company, * *b*, New Castle, Pa.
Norristown Tin Plate Company, *a*, Norristown, Pa.
Phillips Tin Plate Company, *a*, Philadelphia, Pa.
P. H. Laufman & Co., Limited, * *a*, Apollo, Pa.
Pittsburgh Electro-Plating Company, *a*, Apollo, Pa.
Pittsburgh Tin Plate Works, *a*, New Kensington, Pa.
Record Mfg. Company, *a*, Conneaut, Ohio.
Scott & Co., Jas. B., *a*, Pittsburgh, Pa.
St. Louis Stamping Company, * *a e*, St. Louis, Mo.
Somerton Tin Plate Works, * *a*, Brooklyn, N. Y.
United States Iron & Tin Plate Mfg. Company, * *a*, Dennnier, Pa.
Wallace, Banfield & Co., Limited, * *a*, Irondale, Ohio

report that it will be June or July before they get into operation.

The sworn statements of manufacturers show a steady and regular increase of production from quarter to quarter, and taken

I also append (Exhibit 4) a list of stamping and manufacturing companies, who use American sheet iron and steel in the production of articles and wares tinned or terne coated.

Total number of companies, December 31, 1892	42
Number of companies manufacturing December 31, 1892	32
Number of companies building December 31, 1892	7
Number of companies enlarging works December 31, 1892	6
Number of companies making or preparing to make black plates December 31, 1892	18
Production tin and terne plates proper, fiscal year ended June 30, 1892, pounds	13,646,719
Production tin and terne plates proper, six months ended December 31, 1892, pounds	30,709,216
Estimated production tin and terne plates, fiscal year ending June 30, 1893, pounds	100,000,000
Estimated annual rate of production, close of fiscal year ending June 30, 1893	200,000,000
Estimated investment, buildings and plant, close of fiscal year ending June 30, 1893	$3,500,000

† Made no returns quarter ended December 31, 1892.

‡ Making black plates only.

Exhibit 4.—List of stamping or other manufacturing companies who use American sheet iron or steel in the production of articles and wares tinned or terne-coated.

Note.—The following list embraces only such firms or companies as made sworn returns of production to the Government for the quarter ended December 31, 1892:

Acme Shear Company, Bridgeport, Conn.
Avery Stamping Company, Cleveland, Ohio.
American Stamping Company, Brooklyn, N. Y.
Buhl Stamping Company, Detroit, Mich.
Chicago Stamping Company, Chicago, Ill.
Central Stamping Company, New York, N. Y.
Dover Stamping Company, Cambridgeport, Mass.
Eberhard Mfg. Company, Cleveland, Ohio.
Iron Clad Mfg. Company, Brooklyn, N. Y.
Knapp & Pratt Mfg. Company, Geneva, Ohio.
Lalance & Grosjean Mfg. Company, New York, N. Y.
Mix, G. I., & Co., Yalesville, Conn.
Parker Company, Charles, Meriden, Conn.
Sidney Shepard & Co., Buffalo, N. Y.
Wallace Mfg. Company, R. L. & Sons, Wallingford, Conn.

Is This So?

A correspondent in Indiana writes to us to the following effect:

There is one subject I wish you would preach a little about, and that is, some of the old importers of tin plate (claiming now to be manufacturers) are re-branding inferior brands of Welsh tin plates with American names, and putting "American" in large letters on the boxes. They don't even use diligence in getting the old brands off. I have been caught twice by different houses in this way. Another point: I bought plates from one house branded and priced differently, that were exactly the same plate. Now, our American manufacturers will use us up as badly as the Welshman if we don't kick, and I am one of the kickers.

A possible explanation of the first circumstance complained of by our correspondent may be that the plates he procured were some which had been made of imported black sheets, dipped in this country, and repacked in the boxes in which the black sheets were received. As plates so treated would come within the meaning of the law, as "American tin plates," according to the decision of the Secretary of the Treasury, it would be perfectly legitimate to brand and mark them as such. If, however, Welsh tin plates are being palmed off as *bona fide* American productions—which we are loth to believe—it is a very reprehensible practice, and one which would tend to the detriment of the American tin-plate trade in general. As to the second statement, if our correspondent finds for a certainty that he is being supplied with the same plates at different prices, we can only advise him to buy elsewhere. It must, however, be borne in mind that to distinguish between similar plates is difficult, and even experts might not agree in two plates being exactly the same article.

SCRAP.

The American Tin Plate Machine Company have leased the premises at Linfield, Pa., which were for many years occupied by the March Brownback Stove Company. Work is progressing rapidly and it is expected that the buildings will be ready for occupancy in course of a month or six weeks.

A press dispatch from Frostburg, Md., states that a tin-plate plant is about to be established in that city. W. R. Perry and others are interested in the enterprise, and John J. Jones, it is stated, will manage the plant.

Bruce & Cook, importers and dealers in tin plates and metals, 186–188 Water street, New York, have now on sale American terne roofing plates, samples of which, in appearance and quality, appear to be a very desirable article. To the trade the brands are known as P. T. L. and Snowdrop. This house inform us the goods are giving excellent satisfaction to all who have used them, adding that they compare favorably with high-grade imported brands, and can be sold at a price permitting successful competition.

Prize Competitions

$25.00.

FOR MORE THAN six months Weekly Prize Competitions ($10) have been an interesting and useful feature of the *Pharmaceutical Record*, a journal issued from this office and devoted to the interests of the drug trade. These weekly competitions have related to a variety of technical and business questions of interest to druggists, and have brought out a large amount of information of much service to the readers of that enterprising journal. In view of the success of this feature we have decided to announce a similar series of Weekly Prize Competitions on questions of interest to our readers, and invite a general participation on the part of the trade. As the object of these competitions is to obtain information which will be of practical service to our readers, and to discuss questions in which they are interested, we shall esteem it a special favor if any in the trade will suggest subjects for such competitions, which, if deemed suitable, we shall take pleasure in using.

In each competition there will be three prizes—a first prize of $12.50, a second prize of $7.50 and a third prize of $5. The prizes will be awarded for the answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Prize Competition No. 14.

SUBJECT:

Suggestions Regarding the Sale of Spring and Summer Goods.

This competition is for the purpose of drawing out practical suggestions as to desirable methods in regard to the sale of spring and summer goods. Some merchants are negligent in regard to the matter, not giving it the attention it deserves, thereby losing trade, or defer attention to it until too late to do a good business in this line.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

Those discussing the subject are of course free to treat it as they think best, but the following points are suggested as deserving attention:

Putting carried-over stock in salable condition.
When should new stock be purchased?
Preparing room for season goods.
When should season goods be exhibited in the store?
Arrangement and display.
Methods for increasing last year's sales.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

Replies are to be received not later than March 25, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 14.

Our Prize Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 5. Closing March 4.
A Method of Securing a Reliable and Prompt Delivery of Goods.

No. 12. Closing March 11.
Arrangement of Pocket Cutlery.

No. 13. Closing March 18.
The Best Method of Changing a Credit into a Cash Business.

No. 14. Closing March 25.
Suggestions Regarding the Sale of Spring and Summer Goods.

Another subject will be announced in our next issue.

A hot-air register, claimed to be simple and inexpensive in construction, and which can be quickly and easily put together, forms the basis of a patent recently granted to Frederick Burmeister, Cleveland, Ohio.

ROOFING AND CORNICE.

Roof Coverings from an English Standpoint.

The consideration of a roof depends in some measure upon the standpoint from which it is viewed. The roofing materials used in this country are somewhat peculiar to it, and the same is to be said of any other country. Accordingly, when an English engineer or mechanic visits this country he is very apt to see much that is curious to him in our roofing methods. Again, when one of our roofers goes abroad he encounters many things which are worthy of note and which he is eager to describe to his fellows upon his return. The discussion of roofing theoretically, also the esthetical consideration of the topic, may proceed from as many different standpoints as the consideration of different materials used. In a recent issue of the London *Building News* we find the following article on roofs and roof coverings, written entirely from a London standpoint. It contains much that will interest our readers, notwithstanding that it does not deal to any great extent with those materials with which they are most familiar:

In actual execution the roof, of course, precedes the roof covering; but in working out a design it is frequently the covering which decides the shape of the roof. When once settled, it fixes at least the lower limit for the pitch, and it may even have an influence on the question of hips or gables. In olden times this influence was marked. In many districts hip tiles were scarcely to be had; lead hips were too costly for common use, and hips made up with slates and mortar were both unsightly and insecure. This difficulty has long since vanished. Facilities for transit are, from one point of view, even too great. Materials can be so readily taken from place to place that local peculiarities in building are tending to die out. The country—and one might almost say the world—is getting too much alike all over it, and, among other things, we now find tile hips and ridges everywhere. They have, however, usefulness at least to recommend them. They supply a practical want; but this is more than can be said of all the materials which are nowadays becoming fashionable in localities to which they do not belong. Traveling has become easy, but when all places become pretty much alike what will there be to travel for? It is time that all architects set themselves, as some have long done, to fight against this impending uniformity, and it is worth noting how many roofing materials, and how many ways of using those materials, may still be found within the boundaries of England alone.

One roof covering which is dear to painters, though hardly dignified enough for their architectural brethren, is thatch. The recent destruction by fire of a thatched village in the South of England will not help to commend it, even for cottage roofs, to the practical man. Yet, apart from its pleasant associations and its homelike look, it has merits of its own. Sir Epicure Mammon, in the *Alchemist*, when he is scheming to strip the lead from the churches and turn it into gold, proposes to put thatch instead, and remarks, truly enough, that thatch will lie light upon the rafters. And it is not only remarkable for lightness, but for warmth. In the hands of a clever workman all kinds of forms can be produced in it—gables, hips, valleys, and almost everything but gutters. In the Eastern counties it was brought to great perfection, because reeds were abundant, and were used instead of straw. We need not, indeed, expect to see a general revival of thatching, even in the remotest districts; but it would be a great pity to let the art die out, and the only serious objection, the inflammability of the straw, could in all probability be much lessened by simple means.

OAK SHINGLES.

The use of oak shingles is almost confined to spires and *flèches*, and there they may be made extremely effective. If well seasoned and selected, they are durable; where there is a proper lightning conductor they run little risk of taking fire; and in a certain class of work, usually unpretending, though refined, their color and texture are invaluable. A shingled spire in a freestone county looks, perhaps, a little out of place, though one old example at least, and by no means a bad one, may be found in Lincolnshire. On a wooden turret, however, shingles form an ideal covering. They enable the feature to be completed in the same material in which it is begun, and there is a charm in unity, although fortunate accidents may make even patchiness attractive. Shingles, too, from their smallness, are invaluable in giving "scale." The chief objection to them is their cost. This, when the modern contractor is asked to give an estimate for them, turns out to be surprising. Perhaps the reason is that they are so seldom called for. If a country carpenter here and there, in districts where oak is cheap, would make a specialty of these roofs, he might advance his own interests, and they might be less expensive and less exceptional than they now are.

GRAY SLATE.

The nearest approach in effect to oak shingles is produced by excessively small and rather thick gray slates, such as still remain on a few old houses at Penzance. The architect who has not seen these houses or something like them can hardly imagine how much beauty is to be got out of slating. Here it is used close to the sea for wall coverings as well as for roof coverings; and so it is also in South Devonshire—as, for instance, at Totnes. The Totnes people were more ambitious in their slating than their Cornish neighbors. They built their walls of a slaty stone, which was liable to let the driving rain through its laminated beds. To prevent this evil they then covered the walls with slate hanging, and they experimented on this in all sorts of ways. There are slated quoins and slated pilasters, and many other classic or semi-classic details, slated ever. They look as if a scaly eruption had broken out on the naturally smooth surface of an Italian building, and by degrees had covered it. The result is not always agreeable; but the simpler cottages at Penzance, with their slate hanging, are in this respect quite models for imitation. The artistic objections to slating are its even, mechanical surface and its want of tone and texture. In Westmoreland green slating these objections are more or less removed. The slates are thick, to begin with. Then they vary in size, diminishing in courses as they rise from the eaves to the ridge. The color is a pleasant one, and the surface is broken up by the well marked and somewhat rough edges of the slates. The misfortune is that Westmoreland slates are too expensive for ordinary use. But the old cottages of Devon and Cornwall show us how we may get all the artistic qualities of Westmoreland slating, except its color, out of some of the commonest and cheapest slates that are anywhere to be had. They are worth looking at a little more closely.

SIZE OF SLATE.

First of all, the size of the slate in general was very small indeed. Next, it often varied in different courses, somewhat as it does in Westmoreland slating. The olden slater took his slates as they came, and they did not come to him all sorted to one size, as they come to his successor of to-day. Neither did he try to reduce them all to the same gauge. He was a man, with such rudiments of artistic talent in him as most men have, or used to have, by nature. He was not a machine, like the typical modern workman, trying to do, by the imperfect aid of hands and arms, things which could be done much better and more regularly by the unerring assistance of wheels and pinions. Hence he put his mind into his slating; he fitted here, and contrived there and considered how this part would look and how that part would keep out the weather. Along with his small slates, a few larger ones reached him—as big as "Countess" or even "Duchess" sizes. He did not cut them up to match the others, because he had a use for them elsewhere. If his roof had hips, he worked them in there, one big slate ranging, sometimes with two, sometimes with three, or four, or even five of the smaller courses. If his roof had gables, he worked them into the verges just in the same way, and so he was able to make the verges overhang more, and protect the walls from the weather. Again, where his roof abutted against a wall or a chimney, he first tilted it up well, to throw the water off, away from the rubble or the masonry. Then he covered the junction with a carefully executed filleting of lime and hair, or mastic, in lieu of lead, and over this he found a place for some of his strongest and most durable slates of medium size. The use of these was to prevent the water, which was sure to run down the masonry in stormy weather, from finding its way into the house through crevices at the back of the plaster filleting. To accomplish this he built them in like steps, each 10 inches or 12 inches long, and 3 inches or 4 inches in projection, a little way above the raking line which the roof forms against the wall. As the water ran down the face of the work, it reached these stepped slates, and could not pass them. Consequently it either ran over their edges and on to the roof at a safe distance beyond the filleting, or it just

dropped from one projecting slate to the next, until it got down to the eaves. This was the old-fashioned substitute in cottages, and sometimes even in parts of churches, for lead flushings, step flushings and soakers. It cost less and lasted longer. Compared with the modern slated roofs, which, with other things of their kind, so sicken the townsman of to-day that he has to run away as long and as often as he can, to forget them, these old West-country roofs were full of interest, of art and of beauty. But we could not get them, or anything like them, by writing a clause in a specification. It takes a man to make them, and a man whose heart is in his work.

THE USE OF TILES.

The intense ugliness, flatness and monotony of most modern slating have driven our architects to the use of tiles. Now tiles do have some texture, some solidity, some play of light and shade over them, however mechanically they may be laid. With plain tiles the courses cannot be much more than 4 inches wide, and so the "scale" of a building does not suffer by them as it does by slates of the sizes now customary. Plain tiles, too, are not absolutely flat, and their slight curvature gives variety of tone and softness of effect. In Hampshire one sometimes sees tiled roofs, perhaps to mere sheds and outhouses, which seem to have the softness and richness of velvet, even when new. Broseley tiles and others of that class look hard when first laid, and turn black, rather than greenish or browniah, by time. Tiles of a different make or of a different tint mixed at random among them help to prevent the deadness which comes over such surfaces. But the difficulty is to get them mixed at random. The modern slater would rather make them into patterns, or into bands, or into something else that is loud and staring. He cannot appreciate the beauty of a quietly and delicately diversified surface, and if he is not allowed to do worse, he is likely at the least to put into one mass all the tiles which you are introducing to get a little play of color, so that he can go on with his even, mechanical task, and rejoice at having got rid of them. There are places, of course, where patterns may be welcomed. Here, in England, we seldom find them in such places; though we see them often where they would be far better away. But some of the French churches show what can be done, when that sort of doing is desirable, with both unglazed and glazed tiles of the richest colors.

PATENT TILE.

Ornamental ridge tiles are dear to the speculative builder. Like tile patterns, there is a right place for them; but that place is not where he puts them. Fortunately, they make admirable marks for stone throwing, and it is a merit in the street boy, which ought to hide a multitude of his sins, that he does his best to relieve us of these excrescences. Some 25 years ago quite a crop of patent tiles sprang up. They were on the pantile system, or on various modifications of it, and some of them were clever; but the weak point in all of these was that the roof-covering was only one tile thick, so that if there was a crack or a flaw in any tile the water came through at once. For the same reason, roofs covered with them were very liable to injury by workmen, and the result is not only that they are little used in new buildings, but that they have even been removed from older ones. Roman tiles, which have a separate covering piece over the vertical joints, are stronger, and less liable to injury; but English architects have found it difficult to get them properly made. And all these specimens of the pantile type have such a marked and distinctive character of their own that they either jar with or overpower most architectural details.

We have no room to speak of lead as a roof covering. It has a beauty of its own, though in London the smoke and soot seldom let us see it. But the gray roofs of Lincoln are something to remember, and so is a quaint, old, lead-covered spire like that at Braunton, near Ilfracombe. Bleached in places almost silver white, covered with rolls and fragments of rolls, patched up with patterns and ends of patterns, old and new, it looks like a history of North Devonshire plumbers for many generations. But their patching was surely not without expense; and in the quantity of it which has been needed we may see the reason why lead-covered spires are as infrequent as they are.

Perkins Shutters and Doors.

The Borden-Swearingen Shutter & Iron Works, Kansas City, Mo., and St. Joseph, Mo., since taking control of the well-known Perkins patent double-plate air space fireproof shutters and doors have made wonderful strides, which speaks well for the management, as also for the value of this fire-proof shutter. There are, it is claimed, over 100,000 of these shutters in use in the United States, Canada and Mexico, and their sales amounted to more during the year just closed than any two previous years. The Perkins patent swing shutter is constructed on the same principle as the rolling shutter, except in closing it projects into the opening. It cannot be warped by fire, as both plates are rendered stiff by corrugations and cross braces before being put together, the corrugation not only stiffening, but also providing for expansion and contraction, thereby preventing twisting out of position. The two plates are firmly riveted together along the sides, top and bottom, through heavy bands of iron, each plate setting as a brace to the other, so that a degree of heat sufficient to ignite the wood work of doors and windows cannot pass through it.

The 2-inch air space between the plates admits of a rapid circulation of cool air in case of fire, the air passing in at the bottom and out through small slots near the top. The inside plate is thus kept comparatively cool, while the outside plate may be subjected to intense heat. This is a combination claimed to be found only in the Perkins shutter. The top, with the exception of the slots mentioned, is tightly closed, preventing rain and snow from entering between the plates, and the inside surfaces are well painted before putting together.

They are operated either from the inside or outside of the building without the necessity of opening and closing frost-bound windows hard to reach. By attaching one to the other, all the shutters from top to basement on the same side of a building are opened and closed simultaneously at a single point, thus accomplishing in a minute's work that which often takes an hour or more to do with swing shutters, and insures increased protection from the quickness in operating them. They can be used in very narrow spaces where it would be impossible to open and close swing shutters. The tracks on which the shutters roll are set at an inclined angle, so that the shutters as soon as released from their fastenings, which hold them open, quickly roll down and close themselves. The advantage of this feature will be readily appreciated by hotels and others requiring the shutters to be opened constantly, and, in case of fire, readily closed. It is claimed that wind, snow, and ice cannot affect them; that there is no danger of broken windows and hinges torn from the wall by slamming shutters; that snow cannot clog their working, as the wheels or rollers are inclosed between the plates of the shutters.

The Borden-Swearingen Shutter and Iron Works also handle metal roofing and siding, prepared asbestos roofing, prepared felt roofing, incandescent lamps, mineral wool, asbestos and building papers.

FLASHINGS.

THE NATIONAL CORNICE WORKS, of which Schneider & Scheurer are proprietors, Hastings, Neb., have just issued an illustrated catalogue for 1893. The 20 pages of which the little pamphlet is composed give attention to galvanized iron cornices, dormer windows, pediments, finials, window caps, etc. The illustrations show designs for sheet metal work and indicate in a measure the variety of work which the concern now are in position to supply. An important feature of the pamphlet is found in the dimensions presented and the list of prices.

A VERY UNIQUE CARD, intended for the spring trade, is that just issued by Auld & Conger of 100 Euclid avenue, Cleveland, Ohio. Upon one side is a design worked out in slate of different patterns, the inscription reading:

"Auld,
1893,
Conger."

The main body of the design is in light green slate, while the letters and figures are in a deeper shade. The card is intended to show the manner in which lettering and dates can be worked out with slate of different colors, and can be used as a copy, which may readily be followed by the workmen, as the pattern on the card is made to a scale. On the other side of the card is a table, copyrighted by Auld & Conger, giving the number of slate of any size in a square from 1 up to 60. This is very convenient for the workmen in getting out an order or for the truckman, as they can tell at a glance how many slates of any size are required to do a certain piece of work. We understand that Auld & Conger will supply a copy of this card to any one who may be sufficiently interested to apply.

J. H. ELLER & Co. of Canton, Ohio, have issued what is known as their Seventh Annual Catalogue and Price-List. Within its colored paper covers the merits of the goods turned out are set forth and the statement made that the aim in the past has not been to "sell the cheapest, but to furnish a good article at a reasonable price," which high standard, it is said, will be maintained. Attention is given to steel roofing, corrugated iron, roofing and siding, conductor pipes, eave troughs, gutters and Eller's steel roofing. Remarks are presented on the construction of steel roofs, with illustrations of how the specialties of the company are applied. The engravings are numerous and represent goods of a character to prove interesting to those engaged in the roofing business. Price-lists are also given, together with testimonials and diagrams for the convenience of those ordering roofing or siding.

MERCHANT & Co. of Philadelphia are about to put upon the market a metal tile made on the same principle as their Spanish tile, but designed expressly for use on towers. The metal tiles at present on the market can only be adapted to towers by cutting or otherwise altering them to suit the tapering grades, which entails a good deal of waste, as it necessitates the use of as many tiles for the upper or taper courses as for the lower. With the special tiles now to appear, there is practically no waste, as they are made in a variety of sizes, and will run to any taper with little perceptible difference in each course. It is claimed that a great saving in labor is effected by the use of these tiles, as they are as easily applied for upper as for lower courses, the filling being made on an ordinary former. The method of fastening and nailing is the same as that used for the Spanish tile.

"The Metal Worker" Competition in Skylight Pattern Cutting.

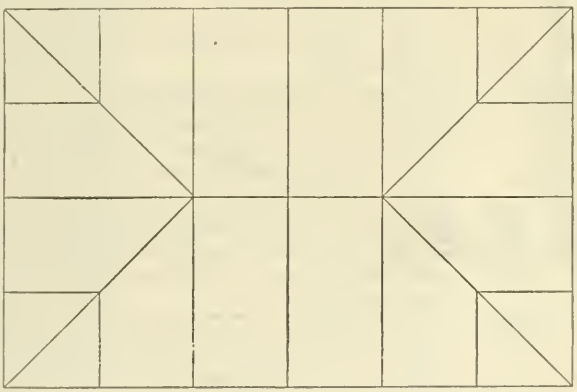
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

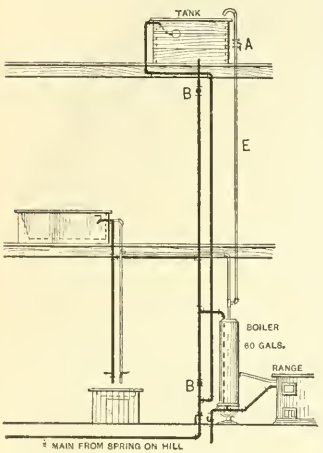
1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

PLUMBING AND GAS FITTING.

A Plumbing Problem.

From N. H.—I inclose sketches of two jobs done in neighboring summer houses. The point involved is this: the plumber who did the work claims that it is all right, while another claims that it is not and that it is dangerous in its present condition. The work has been in use three years and the boilers hammer and kick when there are hot fires in the ranges. It is almost impossible to keep packing in the hot faucets over the sinks. The boil-



A Plumbing Problem.—Fig. 1.—Range Boiler with Tank.

ers are copper. You will notice check valves on the supplies at B and there are no relief pipes to the boilers. *The Metal Worker* has advised other readers under similar circumstances and I would like an opinion as to the safety of the work in question.

Answer.—Accepting the work as shown by the cuts, the principle shown in Fig. 1 is much the better and with some modification it can be made satisfactory. Our correspondent remarks that there are no relief pipes to the boilers. According to Fig. 2, there is no place for a relief pipe. In lieu of the relief pipe, a safety valve might be placed upon the boiler and the drip pipe from it arranged to discharge over the kitchen sink. In any case the check valve B should be omitted; the boiler would then, if occasion required, relieve itself by forcing the water back into the spring supply. Continuing our remarks on Fig. 1, it is evident that pipe E was intended for the relief pipe. We advise the removal of the stop cock A, as there is no probable service it can perform, and allowing it to remain is courting the chances of having it closed when an open way through the pipe is most desirable. Pipe E should be as large as the hot service from which it is taken and no means of closing it at any point should be provided.

With reference to the check valves B B, Fig. 1, they probably perform the service that was intended while the work is in its present condition; that is, the lower one prevents any return of hot water through the spring supply and the upper one prevents hot water from rising into the tank when the boiler is overheated. However, as the spring supply to the tank and the cold service pipe to the boiler and fixtures are already practically two lines of pipe, it would be better to remove both check valves and make the spring supply one continuous line to the tank without any intermediate connection. Then, with the relief pipe E in proper condition, there would be no danger of hot water rising into the tank through the cold service pipe.

In Fig. 2 we notice that the spring supply is much larger than in the case of Fig 1, and we presume other fixtures not shown in the sketch are supplied by it. If on this account it is urged that a check valve is necessary to prevent the possibility of syphoning the boiler by drawing on the supply between it and the spring, the check may be allowed to remain provided a safety valve of some kind is used as before mentioned.

The heating surface of the water backs is very likely excessive in both of the jobs in question. If so, every point that will aid in securing a free circulation between the water backs and the boilers should be taken advantage of. If any of the connections are smaller than the openings proper in the boilers and water backs, they should be enlarged to full size. Notwithstanding that the pipe may be of the proper size, incrustation will sometimes reduce its bore until the result is practically the same as though the pipe itself was smaller. Therefore, in case the hammering continues after the alterations suggested have been carried out, our correspondent had better examine the range connections.

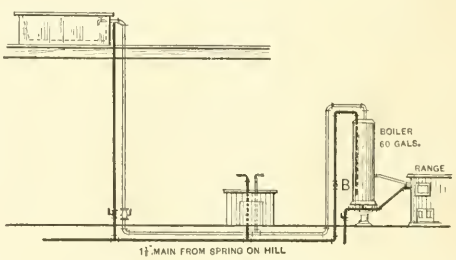


Fig. 2.—Range Boiler without Tank.

Registration of Plumbers in England.

The bill to provide for a uniform system of registration for plumbers throughout the United Kingdom, which was brought before the British House of Commons last year and referred to a select Committee of the House, has been again introduced, with the object of passing it into law. It is expected that the bill will be carried through Parliament at an early date, in which case it will take effect from January 1, 1894.

OBJECTS OF BILL.

According to the preamble of the bill, the chief object is "to afford additional safeguards to the public health, by enabling persons employing plumbers to select, when they desire to do so, persons who have given evidence of their qualification for plumber's work."

"There has been for several years a system of registration of plumbers established in the chief centers of Great Britain and Ireland, and by the bill it is proposed to place this system upon a broader and more permanent basis. The arrangements as to the examinations for registration will be placed under the jurisdiction of a General Council, representing the master and operative plumbers, the Plumbers' Company (one of the great London guilds), and the chief educational and sanitary bodies of the United Kingdom, with branch councils in Scotland, Ireland and Wales. It is proposed also to give the Council power to promote technical education among plumbers, and to exercise discipline among those whose names are enrolled upon the register. The bill does not contemplate any monopoly, and it does not interfere in any way with the rights of non-registered plumbers. It prohibits, however, such plumbers from representing themselves to be registered."

Such is the main drift of the present bill. The Plumbers' Company are, we understand, fathering the measure, as a means of consolidating and systematizing plans which have been already initiated under their auspices for furthering the better regulation of plumbing work in various centers of Great Britain. As will be seen, the bill does not interfere with unregistered men, but merely provides for plumbers who are qualified to pass the

necessary tests of knowledge a status which shall stamp them as efficient workmen.

POWERS OF GENERAL COUNCIL.

The General Council of Plumbers' "Education and Registration" is to consist of the following members: For England six master plumbers, six operative plumbers and six persons who must be members of a local board of health, medical officers of health, or sanitary inspectors. Branch councils in Scotland, Ireland and Wales will consist of two members of each class above detailed, or six in all. These will be elected by the district councils established throughout the country; but not more than two persons residing in the same city or district can be elected to sit on the general or branch councils at the same time. The members will be elected for a term of three years and will be eligible for re-election.

The General Council is to be intrusted with the work of making by-laws for their own procedure; and they will be given a large jurisdiction in regard to the district councils. These will be directed and regulated in great measure by the General Council, who will also make provision for and direct the examinations for registration, and outline the courses of study and practice calculated to promote the advance of sanitary plumbing. In fact, to the General Council is relegated the carrying out of the entire system of examination and registration, as well as the management and fixture of registration fees and general expenses connected with the work.

PROMOTION OF TECHNICAL EDUCATION.

A portion of the income arising from fees is proposed to be devoted toward the support of laboratories, museums, libraries, or lectureships, or for other purposes tending to the promotion of learning and education in connection with the art of sanitary plumbing. A clause of the act makes special provision for rental or purchase of halls, workshops or other buildings, for the purpose of establishing trade schools for the teaching and practice of plumbing.

PLUMBER'S REGISTER.

"The Plumber's Register," containing the names and addresses of all persons qualified under the act, is to be published annually; and with the General Council will lie authority for removing persons from this register for various specified causes, as misdemeanor, incapacity, &c.

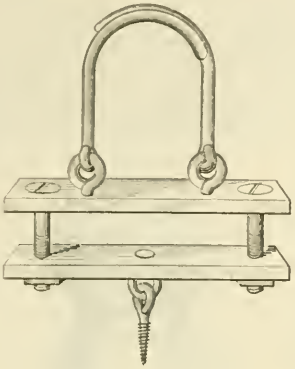
All plumbers whose names already appear on the register of the Plumber's Company, and those persons who have been engaged in business as plumbers prior to March 1, 1886, will be entitled to registration under the new act, without examination.

In its last clauses penalties are set forth for those who willfully misrepresent themselves as qualified workmen under the provisions of the new act. These range from a fine of $100 to imprisonment for 12 months.

Pipe Holder for Wiping Joints.

From S. F. B., *Leechburg, Pa.*—I inclose herewith a sketch of a serviceable little device that comes in every day use for the plumber. It is a pipe holder for clamping lead pipe to the bench or floor when wiping joints or two pieces of pipe together. It was my habit, during my time as a plumber, to use compasses for the purpose, with a pipe wrench or hook, or anything that would hold a pipe steady. With this simple device, of which I send a sketch, the work can be much more quickly and satisfactorily done. I do not claim the article as a patent, but simply send it to you in the hope that it may save some expense to the poor plumber on compasses.

The clamp is made of two pieces of band iron 4 inches long by 1 inch wide and $\frac{1}{8}$-inch thick, with three holes bored in the lower piece, the ones at the end being large enough to admit a sunk bolt of $\frac{1}{4}$-inch in diameter and the center hole large enough to admit a $\frac{5}{16}$-inch rod. This rod has an eye turned on it and is riveted on the lower strip. Before closing up the eye, however, a big screw eye should be put in it for the purpose of screwing it to the bench. The upper piece of band iron has four holes drilled in it, the two outside holes admitting two sunk bolts, as shown in the sketch, and the middle holes being for two more eyes of the $\frac{5}{16}$-inch rods. These eyes are riveted in likewise, and have two hooks passing through them, as shown in the sketch. The hooks are for gripping the pipe, and are fastened as shown. They can be used on pipe of any size or in any place, for horizontal or upright wiping. When the device is screwed



Pipe Holder for Wiping Joints.

in place the tightening can be done by an ordinary screw driver, by turning the sunk bolts.

Syphonage by Capillary Attraction.

From E. J. C., *New York.*—In your issue of February 4, in your remarks on what is called "dog's teeth," you say they are likely to syphon out a trap by "capillary attraction." I have been many years at the trade and I must acknowledge that I do not understand what it means and how the lumps of solder can help to break the seal of a trap. I am willing to be enlightened, however, if you are willing to do the enlightening part.

Answer.—To those who when dealing with effect search out the cause, greater opportunities for the acquisition of information will always present themselves. It is only reasonable to suppose that our correspondent has been often called upon to remove obstructions from traps and on such occasions has found among other things fragments of rags, cloths, thread, twine, &c., lodged in the trap and perhaps trailing over the crown and into the soil or waste pipe opening. Possibly he rested satisfied with having found and removed the obstruction without considering that the long shred of cloth, or other trailing substance, if left undisturbed, would eventually succeed in syphoning out the trap by what is known as capillary attraction or that form of attraction which causes liquids to ascend above their level in capillary tubes.

Defining capillary attraction in the simplest phraseology, we would say that the term is derived from the use originally of small glass tubes in which the liquid rose, the bore of which was not thicker than a hair, and which were called capillary tubes, from the Latin word for hair. The simplest illustration of capillary attraction which we can give is the following, which our correspondent can readily experiment on if he chooses: Let him put a quantity of water in a basin and immerse the end of a towel or strip of cotton cloth therein, allowing a portion of it to hang over the basin's edge. The water will rise through the pores and interstices of the cloth, gradually wet the dry part, and will eventually drip from the part which hangs over the basin, and so continue, if permitted, until the water is drawn out of the basin. The wick of a kerosene lamp wil also furnish an equally simple illustration of capillary attraction, as it is by this force in Nature that the oil is drawn up to feed the flame, which is generally about 2 inches above the surface of the oil. If it should happon that a plumber in putting in the vent in the crown of a 2-inch trap under a wash tray or kitchen sink, for instance, should leave "dog's teeth" behind him, and that thread, twine, ravelings of cloths or other similar substances passing through the trap should get caught in one of these little lumps capillary attraction would at once be established, and, as in the basin, the water in the trap, if not renewed for some time, would be completely syphoned out and a clear entrance permitted to sewer gas. It not unfrequently happens that cloths are carelessly thrown into water closets, and these may also be caught and be the means of emptying the trap. It will therefore be seen how much care should be exercised in the execution of plumbing work so that a well-arranged system of traps and vents may not be rendered almost useless by blundering which might be avoided.

Protection of Water Pipes Against Frost.

From J. F. G., *Opelika, Ala.*—Please give me some of the methods used to protect water pipes from freezing. The plumbing business is quite young in our town and there has been a great deal of trouble with burst pipes in ordinarily cold weather.

Answer.—The most practical sort of prevention of water pipe freezing is, in the first instance, to avoid running the pipes in exposed situations—that is, keep them away as much as possible from the outer walls and from exposed air shafts. If this cannot be avoided in every case the pipe should be covered with some non-conducting material, such as mineral wool or felting, and if such articles are not always available—if the water pipe is so situated as to admit of doing so—it might be boxed and the box filled with sawdust. If the pipe is run in the ground, it should be packed in charcoal dust or laid below the frost line.

Repairing Water Mains.

From W. M., *New York.*—We have a water main which was burst from the frost. Have any of the readers of *The Metal Worker* ever used bolted pipe bands, which are described in the plumbers' catalogues? These bands are made in two pieces to form a sleeve and fit over the pipe. I would like to learn if they give satisfactory results.

The Plumbing Situation in New York City.

The failure on the part of ex-Mayor Grant to comply with the mandatory provisions of the law passed by the State Legislature last year (Chap. 620, Laws of 1892) in relation to the examination, licensing and registration of plumbers, has led to more or less embarrassing complications. Under this law the Chief Inspector of Plumbing, the Chief Engineer of Sewers, two master plumbers and one journeyman plumber constituted the examining board, which should have been appointed within 90 days of the passage of the act. The eight months of Mayor Grant's term subsequent to the approval of the measure by the Governor were allowed to pass without any action being taken, and when in the first week of February of the present year the examining board was created by Mayor Gilroy the task set before the board—viz., the examination of nearly 1000 master plumbers in the short space of two or three weeks—was one utterly impossible of fulfillment. The consequences of this neglect can be readily appreciated when it is understood that under the provisions of the act referred to any plumber doing work in New York City after March 1, 1893, without having been examined and licensed by the examining board and registered in the Health Department, would be adjudged guilty of a misdemeanor. No permits could be issued by the Department of Public Works for opening streets or tapping mains, and the sewerage and water service of the city would, in the truest sense, be left to take care of themselves. The examining board, appointed on February 7, organized for business on the 10th of that month with Col. Geo. D. Scott, Chief Inspector of Plumbing of the Building Department, as chairman, but, with the exception of a small number of the old plumbers who had been in business many years, there was but very little progress made until the advent of March 1 apparently left the plumbers in a bad plight.

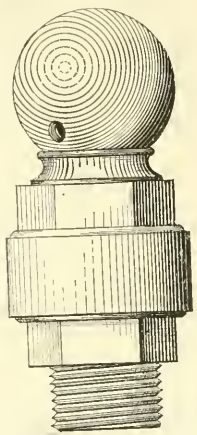
Desirous of ascertaining the status of the trade in this city under the embarrassing conditions above stated, a representative of *The Metal Worker* sought an interview with Colonel Scott at the office of the Building Department on the 1st inst., the date on which the old licenses became inoperative under the new law. The information afforded by Colonel Scott was to the effect that the utmost the examining board could do in the short time it was in existence was to receive the applications of those who sent them, with the statement that they would be notified of the date on which they would be required to appear before the board for examination. Colonel Scott next consulted with Mayor Gilroy and, after explaining the gravity of the situation, the city being virtually deprived of the services of the plumbers, suggested that an extension of time should be asked for to enable the board to complete the revision of the license record. A bill was in the meantime prepared, identical in all its provision with chapter 620, 1892, but extending the time to September 1, 1893, and this was forwarded to Albany with Mayor Gilroy's indorsement. On the 1st inst. a telegram was received by Colonel Scott from Albany stating that the bill extending the operations of the examining board to September 1 had passed both branches of the Legislature and received the Governor's signature. The board will now proceed to business, and the examinations will be held every Friday on the top floor of the Bradley building, corner of Eighteenth street and Fourth avenue, in which the offices of the Building Department are located.

There are at the present time the names of 95 licensed master plumbers on the books. Many of these are names of men no longer in the flesh, but whose licenses are used by their successors in the business. It is, we are informed, the purpose of the examining board to honestly investigate every applicant's claim to be considered a competent plumber, and as the *personnel* of the board is in the fullest sense satisfactory to the plumbers as a body, it is expected that the decisions reached will be accepted as fairly rendered and the standing of the craft be placed on a reliable basis.

Safety Valve for Kitchen Boilers.

In view of the fact that many accidents occur yearly from the explosion of kitchen boilers, an English exchange directs attention to a patent safety valve devised by Mr. Foord of Notting Hill, London, England, which is specially designed for the prevention of such accidents. We give herewith an illustration of this valve, together with the following description from our exchange:

The preventive, which is otherwise known as a "non-corrosive safety valve," is sketched in the illustration and is intended to be fixed either to the high-pressure boiler itself or in the flow pipe, the nearer the boiler, of course, the better. The active feature of the valve is a disk of mica, which is fitted in the circular body. For duly protecting the mica a lead washer is first laid upon the seat. Upon



Foord's Patent Safety Valve for Kitchen Boilers.

that is placed a washer of cardboard, and then upon the latter the mica disk is laid. Over the disk is placed another cardboard washer, and upon that again there is another washer of lead. The ball covering is next screwed on and the valve is ready to be fitted to the boiler or flow pipe by means of the screw shown at the base of the illustration. As mica is of a non-corrosive nature, the valve is always in a workable condition—a feature of prime importance, as need hardly be pointed out, where dependence has to be placed upon a part that may be called into automatic action at any moment, expected or unexpected. Assuming, now, that the valve is fitted and a servant, in ignorance of the fact that the water pipes are badly frozen, proceeds to light a fire in the morning as usual, the worst that will happen will be the bursting of the mica disk, an outrush of steam from the aperture in the ball covering, and a subsequent flow of water, causing a mess in the kitchen, of course; but that will be an insignificant matter, which can be soon set right. The ball covering, it should be added, is intended to be fixed so that the hole is against a wall, and in that position the outrushing steam will not fly in the face of the occupants of the kitchen. Or an alternative arrangement can be adopted where a little extra expense is not a consideration, and that is to carry a small pipe from the valve to the sink or other place where the steam and water can be discharged. The disks are tested to stand a pressure of 65 pounds. The sole agency for the United Kingdom has been taken up by James Dixon, Saracen's Head Buildings, Snow Hill, London.

TRAPS AND VENTS.

In a note in *The Metal Worker* of February 25 we referred to an address at the Third Annual Convention of the Connecticut Master Plumbers' Association, held at New Britain, Conn., February 9. The name of the speaker, however, should have been President L. H. Mills of Bridgeport, instead of Lyman D. Mills of Middletown.

The Keystone Gas Meter Company of Royersford, Pa., send out advertising matter of an interesting character. In addition to the *fac-simile* of a reprint from a foreign paper, to which we referred some time ago, they also distribute a little spring circular addressed to all gas companies, calling attention to the merits to be found in the Keystone meter. A serviceable souvenir is a blotter. Cards are also distributed, giving tables of burners, pipes, &c. The figures show the size of the meter, greatest number of burners to be put on it, and the size of pipe to be used, the meters varying from 3 to 500 light each.

The committee of the New York Master Plumbers' Association having in charge the presentation of a portrait of Col. Geo. D. Scott, Chief Inspector of Plumbing of the Building Department brought their labors to a close on Washington's Birthday, when the portrait was presented to Colonel Scott at a drill and reception held on that evening at the armory of the Eighth Regiment, of which he is Colonel. The presentation was made by President H. G. Gabay of the Master Plumbers' Association. The portrait is full life size, and represents the Colonel in full uniform. Accompanying the portrait was a handsomely engrossed set of resolutions suitably framed. The occasion was well chosen on which to make the presentation, as the regiment was being reviewed on that evening by Mayor Gilroy in the presence of a large assemblage.

"There are men," says a London (England) plumbing exchange, "who, from ignorance and incapacity, are unable to obtain the certificate of the registered plumber, yet they have the brazen effrontery to style themselves 'sanitary engineers.' One of these in a populous Southern suburb dubs himself an 'undertaker and sanitary engineer.' He was asked if he was a member of the Sanitary Institute. 'No,' said he, 'I belong to two local clubs, and that's quite enough for me!' Such a questionable qualification may perhaps bring him some 'nice funerals' of defunct members, but it is to be hoped that his sanitary knowledge will be held at a very low estimate."

Taking time by the forelock, the official commission for the International Exposition to be held in or near Paris in 1900, has already commenced its labors.

The Patent Office exhibit at the World's Fair will, according to the annual report of the Commissioner of Patents, comprise some 2500 examples, mostly working models, classified and arranged in chronological order; beginning, for instance, with the first elementary idea of a machine, or other object, and carrying it out through the successive stages of its development to the latest improved type. The collection should be of great interest and of remarkable educational value.

Western men are not at all pleased that in the Senate appropriations in aid of river and harbor improvements between Buffalo and the Soo Canal have been cut down about one-half.

THE RETAIL STORE.

The Stove and Tin Business.—I.

BY VETERAN.

There is no end to the study of business methods as related to what is called the stove and tin trades—no institute where one can graduate. It is the work of time and close application to methods that from time to time show best results. One must be as ready for a change to suit circumstances as a mariner looking to his course and the weather. There are, however, certain standard and reliable guides for business that must be in the foreground, and to which rules must tend. The first in importance is for the dealer to make up his mind what kind of trade will best pay him for his services and capital, at the same time taking into consideration his own age, experience and natural inclination.

A young man with small means, good health and a fair knowledge of the mechanical details can go to a new country and open up without much regard to style, and with his own hands make a stock of tinware cheaper than he could buy it and pay freight to distant points. His time is thus employed from the start, and he can play the old tune of "hand-made goods" for all it is worth and can get good profits on his labor. In the opposite extreme is the tony city store, located, without regard to expense, in the heart of business, with elegant fixtures, full lines of stoves and housekeeping goods, plated ware, clerks with high-standing collars, and where a common laboring man would never think of going to get his stove pipe fitted up or a leaky vessel mended.

Between these extremes are at least three grades of business. One is where no attention is paid to sales of merchandise and but a few of the most useful articles kept, but where it is all work, work, work, do anything from cleaning a furnace to putting up a corrugated iron building, and where a good, tight building in an alley will answer better than an elegant store in a block on the best street at same rent.

Next comes the combination business, where an effort is made to unite a store trade with shop work, and this is the business of the larger part of men known as stove dealers. Most of these concerns dabble in plumbing, gas and steam fitting and sell agricultural implements and builders' hardware.

Quite an important branch is that confined to furnaces, ranges, heaters and grates alone. This is naturally limited to the large cities, where nearly every new building has the heating and cooking apparatus permanent. This includes the various methods of hot air, steam and hot water. A few concerns are engaged in the sale of gas appliances for heating and cooking, but find the competition of the gas companies too much for them, as the goods are offered at the lowest wholesale prices at these establishments, solely depending on the increased use of gas for compensation.

The dry goods and furniture stores are in the business apparently to stay, and are sharp competitors; but as they do not strictly come under the head of stove dealers, they need not have attention or advice unless from the dealers who supply them, for they are looked upon as intruders by the trade in general. There is no good reason why an energetic dealer may not hold his own against these stores. There is but one way to do it, and that is to learn by personal knowledge and not by their advertising just what kind of goods they keep and the prices at which they are sold, and then to match them fairly.

Leonard Cleanable Hardwood Refrigerators.

Grand Rapids Refrigerator Company, Grand Rapids, Mich., are putting new styles of refrigerators on the market for 1893, one style of which is shown in the

The Leonard Refrigerator.

accompanying cut. In the new patterns the carving is changed from the old-style spindle work to conventional designs cut in the solid wood. They have also replaced the iron hinges with false ornaments by solid bronze surface hinges made at their foundry. The interior arrangement of the refrigerator is so made, it is stated, that not a nail head shows in the zinc work. For insulation charcoal filling is used, and as an extra safeguard against its settling down, an extra lining of heavy wool felt. The wool felt is nailed on the outside of the inside box. Their line of sideboard tops for refrigerators is referred to as artistic, and as not only useful, but highly ornamental, only the best bevel plate glass being used in these tops.

The Bristol Automatic Fishing-Line Float.

The Horton Mfg. Company, Bristol, Conn., are introducing the float shown in Figs. 1 and 2. Through the center of

Fig. 1.—Automatic Fishing-Line Float.

the float is a hole, into which at the small end is introduced a bent piece of metal. Between the parallel sides of the metal is a small clamp so arranged to hold the fish-

Fig. 2.—Interior Construction of Float.

ing line between it and one side of the metal. The float is thus securely fastened at any position on the line desired. In reeling up the line the float is automatically released from the line by the attachment tripping as soon as the end of the rod comes in contact with the float, as shown in Fig. 2. While the float is easily adjusted to the line, it as easily detaches itself, thus saving all annoyance and inconvenience and relieving the fisherman of all necessity of looking after his float while landing his fish. The automatic attachment is neat in construction, being but little larger than the ordinary wood or quill center in floats.

Gem Water Filter.

Edward G. Shepard, 142 Chambers street, New York agent for Jones Mfg. Company, Boston, is offering the above filter, as illustrated in the accompanying cuts. The filter, Fig. 1, is made of brass, nickel plated inside and outside, to give

Fig. 1.—Gem Water Filter.

protection from rust or corrosion. It is claimed that there are no soldered or complicated parts in their construction, and the caps at each end are held to the body by three screws, which may be removed at will. The filters are packed, it is stated, with especially prepared ground quartz, held in place by nickel-plated

Fig. 2.—Showing Distributing Disk.

brass strainers of woven brass wire. As shown in Fig. 2, a distributing disk is suspended in the center of the filter, and is designed to divert the flow of water from a straight course, break it into a spray and throw it into all parts of the filter, thus, it is claimed, greatly increasing its filtering properties. The glass filter, Fig.

Fig. 3.—Glass Gem Filter.

3, is constructed the same as the one already described, except in its external construction, glass being used for a body instead of brass. This necessitates the use of outside screws to hold the parts together; but it is readily taken apart for refilling, and allows the working of the filter to be seen, and also the condition of the filtering material. The glass is ¼ inch thick and, being cylindrical, the makers remark that the objection of breakage is almost entirely removed. Fig. 4 shows an attachment for plain bibbs, those having no threads, to fasten the filter to. By means of the attachment these filters may be placed upon smooth faucets of varying

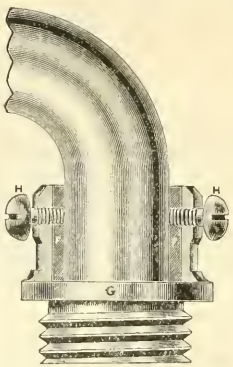


Fig. 4.—Plain Bibb Attachment.

sizes. The interior part F F is a piece of rubber tubing, held in place by the nickel plated brass cylinder G, having the necessary filter thread, and the whole fastened to the faucet by two set screws, H H. The attachment is made in nine sizes from $\frac{7}{16}$ to $\frac{15}{16}$ in $\frac{1}{8}$ inch sizes.

Twist Drill Gauge.

We illustrate herewith a new twist drill gauge, the opposite sides being shown in Figs. 1 and 2, manufactured by T. F. Welch & Co., 65 Sudbury street, Boston, Mass. The tool is made of cast steel, hardened. The holes, it is stated, are gauged accurately, and the principal improvement embodied in this tool is that it combines a drill gauge with the tap drill sizes. This is accomplished by indicating on reverse side the tap drill sizes by means of numbers. It is claimed that this is a great advantage over the old method of guessing the sizes required by the different taps. The point is made that the tool is well made and finished and sold at a moderate price.

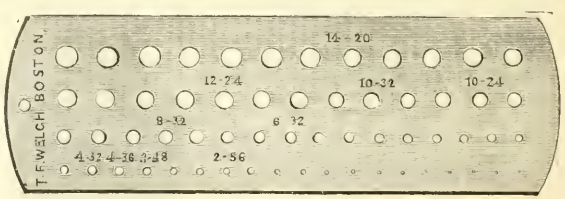

Fig. 1.—Twist Drill Gauge.

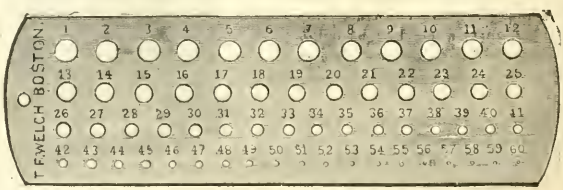

Fig. 2.—Gauge for Taps.

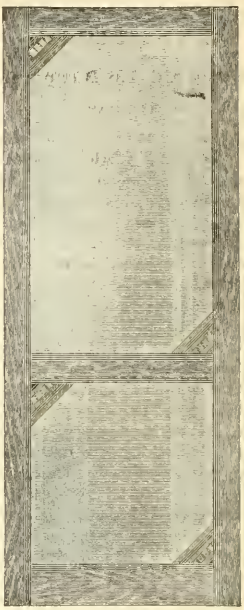
McFarren & Shutts is the style of a firm who have recently commenced business at Hornellsville, N. Y. The stock carried will include House-Furnishing Goods, Glassware, &c.

The Empire Fancy Screen Door.

The new pattern of screen door, as herewith illustrated, is manufactured by A. J.



The Empire Fancy Screen Door.

Phillips & Co., Fenton, Mich. It is made from selected pine, finished in natural wood, wood filled and varnished. It is referred to as having dowel joints, stiff, strong and handsome, and as first-class in every respect. It is made in six sizes, from 2 feet 6 inches by 6 feet 6 inches to 3 x 7 feet, ¾ and 1⅛ inches thick, covered with black wire cloth, unless otherwise ordered. The manufacturers advise us that the work and material on the door are first-class, but that the design admits of rapid manufacture, and consequently the door can be sold at a low price.

Herrick's Tool Brackets.

Brackets for hanging tools, as shown in Fig. 1, are being introduced by F. A. Herrick & Co., 228 Second street, Jackson, Mich. The brackets are made of cast iron, notched so that each tool is secure in its place. A strong dovetailed projection plate is screwed to the wall, over which the bracket is slipped. This permits the removal of the bracket at any time without taking out the screws. Brackets are made in three styles: For long-handled shovels, holding six shovels; for long-handled forks, holding eight forks, and straight smooth arm hooks for

Fig. 1.—Herrick's Tool Bracket.

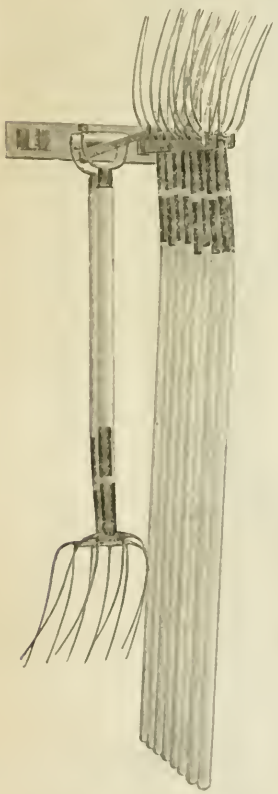


Fig. 2.—Brackets in Use.

D handled goods, that work well between the brackets and economize space, as shown in Fig. 2. The brackets are particularly designed for use in stores where floor space cannot be spared for tool racks.

The Wayne Self-Measuring Oil Tank.

The Wayne Oil Tank Company, Fort Wayne, Ind., are, among others, introducing the two forms of tanks shown in the accompanying illustrations. Fig. 1, their first floor tank, is encased in Southern pine, highly finished in natural wood, and attractive in appearance. The pumping apparatus is composed of metal entirely, being made with such accuracy, it is stated, as to require no packing. The indicator to this, as to all their tanks, is a simple contrivance indicating the exact quantity of liquid in the tank at all times. Stops attached to the pump regulate the amount of oil drawn at a single stroke, whether it be a quart, half gallon or gallon.

In measuring the quantity of oil desired to be drawn, it is explained that the proper stop is pushed inward, while raising and lowering the lever forces the exact quantity of oil indicated into the

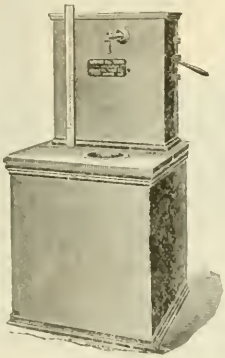

Fig. 1.—First Floor Oil Tank.

can or vessel, which is suspended on the discharge, thus avoiding the use of any and all measures and funnels. The advantages claimed by the makers are that all drippings are carried back to the tank; that the entire operation can be performed in the dark if necessary; that the drawing is rapidly done, leaving clean hands, avoiding greasy, bad smelling floors, checking all evaporation, and that the result is an exact measurement in every instance.

Fig. 2 illustrates their cellar tank and connections, the cabinet of which is above the floor, requiring but little space, and is carefully finished. The drip basin on the floor is to return all drippings to the tank, keeping the surroundings clean at all times.

Among the features for which the makers claim superiority are: That the plunger, being attached to a ratchet movement, operated by a lever, results in producing a quicker action with very much better results and greater ease than by direct motion; that it is made of solid metal, requiring no packing, and does not wear out or leak; that the valves are made of the best brass, ground air tight, and in the construction of the tanks only the best galvanized iron is used; that all measuring adjustments are on the outside of the tank or exposed so as to be accessible at all times, and that the pump can be connected to any sized tank.

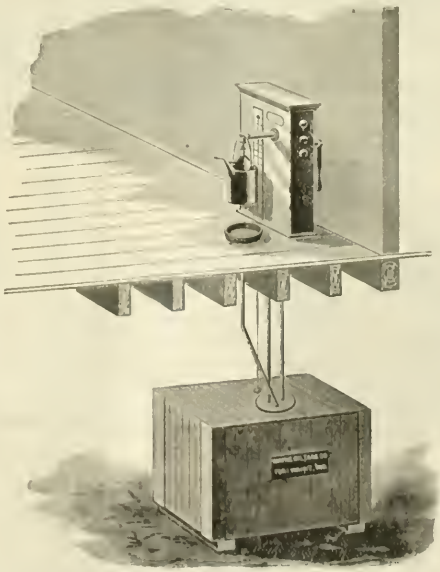

Fig. 2.—Cellar Tank and Connections.

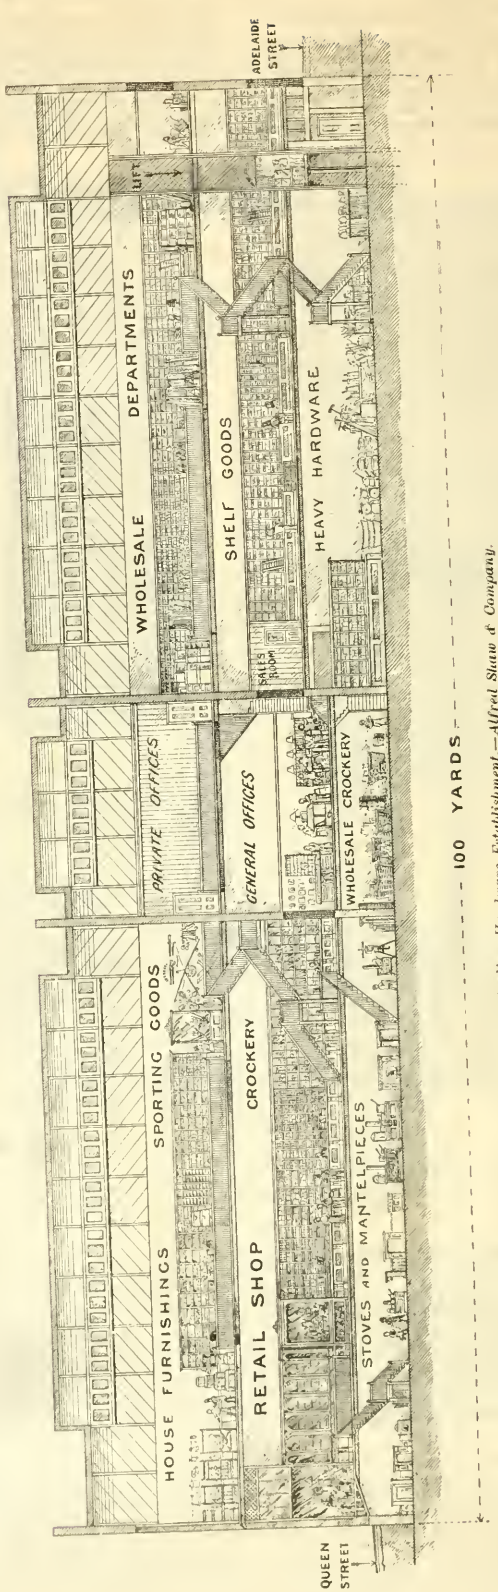
Leonard Cleanable Hardwood Refrigerators.

Grand Rapids Refrigerator Company, Grand Rapids, Mich., are putting new styles of refrigerators on the market for 1893. In these the carving is changed from the old style spindle work to conventional designs cut in the solid wood. They have also replaced the iron hinges with false ornaments by solid bronze surface hinges made at their foundry. The interior arrangement of the refrigerator is so made, it is stated, that not a nail head shows in the zinc work. For insulation charcoal filling is used, and as an extra safeguard against its settling down, an extra lining of heavy wool felt. The wool felt is nailed on the outside of the inside box. Their line of sideboard tops for refrigerators is referred to as artistic, and as not only useful, but highly ornamental, only the best bevel plate glass being used in these tops.

The company advise us that advertising matter for agents is in course of preparation, and will be of an attractive and ornamental character; a blue enamel sign to go under the window sill is one feature, a complete catalogue in miniature is another, also new designs in picture cards and show cards.

An Australian Hardware Establishment.

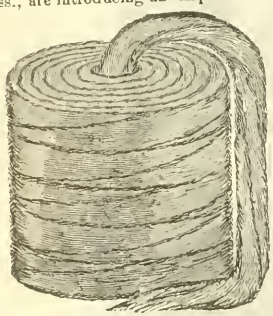
In the illustration herewith given we present a view of the interior of Alfred Shaw & Co.'s extensive Hardware establishment at Brisbane, Queensland. As indicated in the engraving, the building is 300 feet long, running from Queen street to Adelaide street. It has an L at about the center which is over 100 feet in length. A short distance away is a large Implement and bulk store, besides several acres of sheds and buildings where the firm's stock of Agricultural Machines, Metals, &c., is carried. As is true with most Australian Hardware houses, Alfred Shaw & Co. carry quite a line of Crockery and Lamps in addition to the regular Hardware and related lines. We are advised that they purchase about 20 per cent. of their Hardware from the United States, and are, in fact, referred to by competitors as an American house because of their seeming preference for this country's goods. They are large buyers of American Agricultural Machinery and Tools, and are agents for a leading manufacturing concern in the States on these goods. They have lately opened a Sporting-Goods department, and have imported from the United States Fishing Tackle, Bicycle Sundries, &c. The purchases from America would represent a higher percentage of the total purchases were it not for the fact that the heavier lines are all purchased from the old country, such lines including Galvanized Iron, Bar Iron, Horseshoes, &c. Alfred Shaw & Co. do a large retail business, as well as the heaviest wholesale trade in their territory. Being so far from the markets, they have to carry an exceptionally large stock of goods, and they state that if they turn their stock once and a half in a year they are doing very well. As an illustration of the early character of their purchases we may say that they are now ordering the goods which will be in demand next Christmas. The firm were organized in 1875, and by judicious enterprise and well-expended energy have increased their business from year to year until they are now doing the largest Hardware business in Queensland, and carry regularly a stock the value of which is estimated at $500,000.



An Australian Hardware Establishment.—Alfred Shaw & Company.

Coiled Oakum.

The Henry B. Newhall Company, 105 Chambers street, New York, and Boston, Mass., are introducing an improved form



Oakum in Coil.

of coiled oakum, as here shown. It will be seen that the strand is drawn from the center, as twine is drawn from a ball, the size of the strand being easily increased by folding or diminished by dividing it. The convenient form of putting up this article is referred to by the makers as especially desirable to consumers and dealers in oakum, thereby saving much time and waste, which frequently equals the cost. It is said to be particularly adapted to ship calking, plumbing, water pipes, &c. The material used in the manufacture of this article is new Russia hemp, and is put up in 5 pound coils ready for use, 10 coils to the bale.

Testing the Air in Buildings

The Department of State Inspection of Schoolhouses, Factories and Public Buildings in Massachusetts appears, from the annual report of the chief of the department, just issued, to be extremely active in insuring the proper ventilation of the buildings under its charge. Detailed reports are presented by the staff of inspectors in regard to the results obtained by them in their several districts, which show a marked advance in this important matter. These officers are, we are told, men who are well equipped for the work intrusted to them, and the results of their energy are apparent in the improved sanitary conditions which they have been instrumental in bringing about, especially in the case of school buildings. The vital necessity for maintaining a high standard of purity in the air supply of such places, where children are congregated, by means of effective ventilation, appears to have received very earnest attention. Mr. Wade, chief of the department, in his report, urges very strongly the desirability of legislation which shall give the inspectors larger powers in the matter of enforcing the provision of proper ventilating methods in all such cases.

METHOD OF TESTING AIR.

Among the means utilized by the inspecting officers for measuring air supply to, and exhaust from, occupied rooms and the testing of that air in order to ascertain its relative purity, humidity and temperature, is an instrument called the Wolpert air tester, after its inventor, Professor Wolpert. This instrument is very simple, consisting of a glass test tube, on the bottom of which is a black mark, an inner tube of glass, and a rubber bulb, together with a stand to hold the tube. The test tube is filled to a certain hight, marked on the tube, with lime water; and by means of the inner tube and bulb air from the room is passed through the water until by the formation in it of carbonate of lime, the water is rendered so opaque that the black mark or spot can no longer be seen. A table shows, by the number of times the bulb has been filled, how many parts of carbonic acid there are in 10,000 parts of air. This system has by comparison been found to correspond very satisfactorily with more elaborate chemical analysis made at the same time. Its ready method of working and simplicity of operation have been found very useful by the inspectors, who have become very expert in its use and in that of the other apparatus adopted for testing the heating and ventilating systems of schools and other buildings.

THE CARBON DIOXIMETER.

Another device for ascertaining the amount of vitiation in the air of occupied rooms has, we learn from Mr. Wade's report, above quoted, been recently introduced by that officer, which promises to give even better results, without continuous contact of the operator, so that any person may at once be warned by the instrument when the air of a room where it is fixed has become vitiated. This instrument has been called a carbon dioximeter. The apparatus consists essentially of a balance, inclosed in a glass case, with an electric bell attachment. Sufficient willow charcoal is placed upon one scale pan of the balance to absorb the carbonic acid gas contained within the glass case. The larger the amount of carbonic acid gas present the more rapid the absorption. The balance is so constructed that, in air containing ten volumes or more of carbonic acid gas, sufficient absorption will occur within 15 minutes to move the indicator to a particular point on the scale, where an electric connection is made and an alarm bell rings, thus announcing that the air is dangerously vitiated. As when carbonic acid gas reaches 10 or 12 parts per 10,000, we know that the air is charged with matter exhaled from the lungs of those present to an extent dangerous to health, the value of a device which gives instant warning of the fact that the danger line has been reached is obvious.

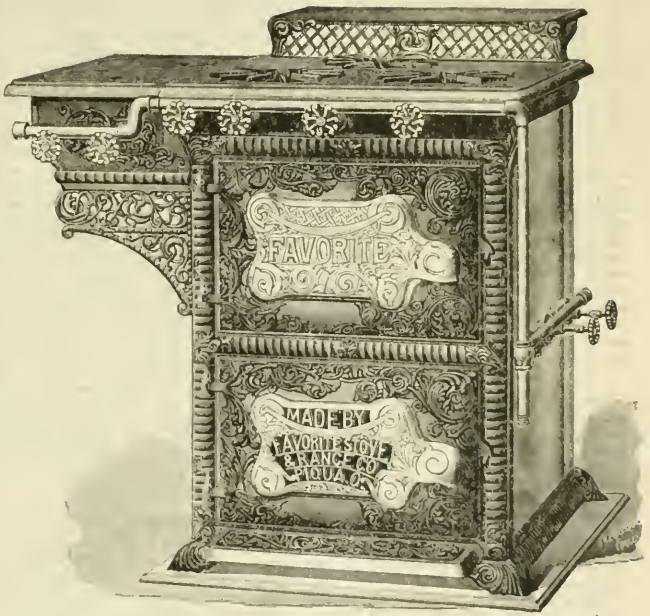
TESTS IN AN UNWHOLESOME SCHOOL HOUSE.

That some such device is, or was, badly needed is instanced in the report by the case which occurred some time since of a school building in which the inspector reported the ventilation to be quite inadequate. The report of an expert chemist in this case showed that samples of air taken from the schoolroom on the first floor, which contained 39 pupils, had in it 15 volumes of carbonic acid gas to each 10,000 volumes of pure air. The sample taken from a room on the second floor, in which there were a teacher and 44 pupils, contained 32 volumes of the gas in each 10,000 volumes of air. A sample taken from another room on the first floor yielded 36 volumes of carbonic acid gas to 10,000 of air. The first sample was taken after the windows had been opened 4 inches, and the third after the windows had been closed 20 minutes. Of the first sample the assayer reported, "It is undesirable for respiration;" of the second, "unfit for healthy respiration," and of the third, "the air is highly contaminated and positively unfit for respiration." The value of any practicable means of doing away with such a state of things, and the efforts which are being made to that end by securing effective ventilation of schoolrooms and other public buildings by the Massachusetts State authorities, cannot be overrated.

Governor Flower has concluded not to interfere at present with the sentence of the court in the case of James Hughes, the Master Workman of the Clothing Cutters branches of the Knights of Labor, who is serving a sentence of one year for the crime of extortion, in the Monroe County Penitentiary.

The Favorite Gas Range.

In the accompanying illustration we present a general view of a four-burner Favorite gas range, which has recently been placed upon the market by the Favorite Stove & Range Company of Piqua, Ohio. In this stove, we are informed, any kind of gas may be employed as a fuel, according to convenience. One of the special features to which attention is invited by the manufacturers is the fitting of the joints, doors, &c., while the ornamentation is of a character to please the eye. The stove here shown, which is but one of a large variety of styles and sizes which are being offered the trade,



The Favorite Gas Range with Hot-Water Attachment.

has four burners in the top plate, one of which is a double burner, and a hot-water heating attachment. Over the hot-water heater are two cooking holes which may be utilized when desired, thus giving six holes for cooking purposes. The ovens measure 8 x 18 inches and have a hight of 12 inches. The cast front doors and polished steel bodies, it is stated, will not tarnish or discolor, and are easily kept in good condition. The top oven plate is made of cast iron and there is a hood to catch all drippings. All burners are operated with steel needle point valves, with stop to prevent thread entering the packing. The double-oven burner has two valves. Some varieties of the Favorite gas range are provided with a step at the side, which has a powerful double burner and is intended for the reception of a portable oven, wash boiler or other vessel. The oven racks are adjustable and the ovens themselves thoroughly ventilated. The company's hot-water attachment can be mounted on any of several sizes in a few moments, thus avoiding the necessity on the part of the dealer of carrying all sizes in stock with hot-water attachments in order to have a complete assortment of the company's goods.

Carelessness in Pipe Fitting.

Habitual fault finding is not an agreeable trait, even when it may have a legitimate cause; but there are occasions when adverse criticism is not only excusable, but necessary. In this category may be fairly included the inexcusably careless manner in which so important a matter as pipe fitting, whether it be for gas, steam or water, is so often performed. Bad work is so common that where the job is a really good one—that is, as good at it always should be—it becomes conspicuous as something super extra by comparison. Of course, this should not be so. The bad job should be the noticeable one. There is neither fairness, nor even common honesty, in doing work at the expense of another in a manner which will cause him to suffer inconvenience or loss. The work is charged for at a price presumably sufficient to pay a fair business profit on cost of material and workmanship of good quality, and if either of these items be inferior (unless by special agreement between the two parties to the contract), the seller does not deliver what he sold and the purchaser is defrauded. That the former may be ignorant of the facts where bad work is done is no excuse; his responsibility to his customer renders it incumbent on him to know that the delivery is in accordance with the terms of sale. He, as the principal in the transaction, cannot delegate his responsibility to an agent, for, though the latter is responsible to him, that is a matter solely between themselves, and with which the customer has nothing whatever to do. He will naturally look to the party with whom the contract was made to see that the work is properly done.

LACK OF SUPERVISION.

There is too much trusting to subordinates and irresponsible employees, and not enough competent supervision, either in person or by deputy; and there is no doubt that much of the bad work done is due to this cause, while the employer neither intended nor is cognizant of the fact that it is other than it should be. In such cases, of course, while it may affect his reputation as to reliability, there can be no reflection on the honesty of his intentions.

There is, however, another phase of the matter, in which the effects are so far-reaching as to constitute a serious evil, and which—judging from the existence of self-evident facts—proves conclusively to be the result of dishonest intention. We refer to the class of work commonly made the subject of competitive bids, for which the contract is usually given to the lowest bidder, regardless of other considerations than the price bid and depending on the written specifications as to all details. For several reasons, however, this class of work is one which is peculiarly dependent on the honesty and reliability of the contractor. In the first place, while ostensibly complying with the specifications, the system of piping, &c., is generally out of sight, and therefore practically beyond the reach of efficient final inspection, which would be necessary to enable the detection of defects of material and workmanship. Then, too, such defects are usually of a character in which the effects may not become apparent immediately upon use, but develop in the course of time.

As a rule, however, no attempt, or pretense even, at such inspection is made, and the contractor, knowing this, and that any bad work is almost certain to remain undetected until all settlements on account of contract have been made, avails himself of the opportunity presented, and upon which he depended when making his estimate of cost, to enable him to bid enough lower than his competitors to secure the contract. Of course the close competition existing in large business centers is the cause of this state of affairs, as it is hardly to be doubted that, if sure of the job, the bidder would name a price at which he could do good work and realize a fair profit. But, in order to secure the contract, he will name a figure below the actual cost of honest work, and depend on "skinning" the job for a margin of profit even below what would be entirely legitimate for honest work.

CONTRACT WORK.

The buildings offering the greatest opportunities for such practices are that class of dwellings which are "built to sell." Not only the plumbing and pipe fitting, but all the different branches of work entering into the entire construction, are thus "skinned" down to the very bottom notch; and the result is that the unfortunate purchaser or tenant becomes possessed of a house which, while possibly of attractive appearance, is utterly deficient in all of the essential qualities of a comfortable, convenient and healthy home. There is, however, no one class of work entering into house construction which has so great an effect on the health of the occupants as that of the plumber. Where the work is badly planned and executed, the water closet, bath, stationary washstands and sinks may become veritable death traps—disseminating the deadly sewer gas throughout the house, and contaminating the atmosphere with the germs of diphtheria, scarlet fever, and all other diseases of a typhoid character. And not the least serious feature is the fact that this state of things may continue for a long time without the cause having been located, or even suspected. The layman in matters of sanitation is not, as a rule, aware of the dangerous effects of bad plumbing; and it may be hard for him to realize that so apparently simple and imperceptible a cause can lead to such serious results. For this reason, there may occur one case after another of sickness, and even death, before the cause is located and the only remedy applied.

INCOMPETENT WORKMEN.

But aside from such cases in which the work is intentionally slighted, there are those first alluded to as resulting from the employment of careless or incompetent workmen. Let us glance at a few of the many common defects existing in a system of wrought-iron piping for steam or water, say, a main line with numerous branches, valves, cocks, fittings, &c. There will be more or less cutting to lengths, for which accurate measurement should be made, to enable the pipe to fit in its place without forcing. But accurate measurements cannot be made by turning an extended 2-foot rule end over end as fast as a man can walk, though this is a very common practice. Either a measuring rod long enough for the purpose or a tape line should be used. It will always pay to have a wooden rod of, say, 1 inch square by about 16 feet long and another of half that length, as it is both more convenient and accurate than a tape measure By holding it in the position of required length of pipe to be cut, and marking with lead pencil, there can be no mistake, as might happen in reading from a rule or tape, and the length can be made sufficiently accurate without requiring special care in the marking, either in taking the measurement or in transferring it to the pipe to be cut.

The next thing is to cut to the mark, not ¼ or ½-inch one side or the other of it. Then as to threading the new end. It is a very easy matter to cut a thread practically true with the body of the pipe. But it is also easy, as well as very common, to cut it more or less crooked and the effect of this is serious, as will be referred to later on. All modern stocks for carrying the ordinary solid pipe die are provided with a full set of guide bushings—one for each size of die, and if they be used, and are in reasonably good condition it will be much more difficult to cut the thread crooked than straight. But owing to the ordinarily chaotic condition of the tool box, with its conglomeration of taps, dies, tongs, nipples, fittings, &c., the rummage for the right sized bushing is not always successful, all sizes not wanted are there, but they won't do. Then, after a very superficial search on the work bench or floor, among the tools and fittings scattered there, the search is given up and the thread cut without the guide. Of course, it is crooked, but "it don't show." The next dive into the tool box in search of something else, the missing guide is pretty sure to come to light. Or it may be that it had been found and used in the first instance, but from constant wear the hole had become so much larger than the pipe as to allow the die to start crooked. Of course it could not be out of true to the same extent as if none had been used, but still enough to spoil a good job.

CONDITION OF DIES.

Then, the die used may have been badly worn and dull, with half or more of the teeth points gone. This will give a thread that will render a tight joint almost impossible. The remedy for the above-named difficulties is obvious. Keep the dies and bushings in good order, and don't attempt to use them after they are sufficiently worn to affect the quality of thread cut by them—new ones are cheaper—and keep the hand tool box for its legitimate use. It is not any larger than necessary to properly hold the requisite tools; and when to these are added the miscellaneous accumulation of materials, there is sure to be much inconvenience and unnecessary loss of time, which somebody must pay for, to say nothing of bad work as the result of not being able to find such as are needed.

It is sometimes more convenient to lay the larger tools on the floor where the work is being done. This is all right, provided they are laid where they will be in plain sight and not allowed to become hidden by carelessly throwing them down among rubbish; but never put the smaller tools anywhere but in the tool box, or there is sure to be a hunt for them when wanted, and the box is sufficiently portable that it may always be kept within easy reach.

The next point from which trouble may arise is the neglect of the workman to carefully inspect the fittings before attempting to screw them into place. First, they should be examined to see that they are perfectly sound. All cast fittings are liable to have blow holes in them, some of which are quite small and have passed the manufacturer's attention, though possibly easily detected if looked for. This is more likely to occur in malleable than in cast-iron fittings, though not infrequently in the latter. There is also, occasionally, a fitting in which one or more of the threads has been tapped crooked; that is, they are not true with each other. This is easily detected by a good workman as soon as they are screwed into place by hand, and they should be promptly rejected for either of these imperfections. Sockets—or as sometimes improperly called, "couplings"—are of lap-welded or seamless wrought iron or mild steel. They are very rarely imperfect and need only a glance by way of inspection.

MAKING SCREWED JOINTS.

Now, as to making the screwed joint. Don't smear the threads with great daubs of red or white lead. A perfect pipe

thread is designed to make a perfectly tight joint in the thread itself, without the use of any foreign material, except, perhaps, by way of lubricant; and if it cannot be so made tight under any pressure to which the pipe should properly be subjected, no amount of red lead or putty will make it so. Much trouble is caused through its use, particularly when it is carelessly applied. The work is usually performed by the apprentice or helper, whose judgment is not of the best, and his idea of doing it is to be sure to get on enough. The result is that there is apt to be enough and to spare, as both the outside and inside threads are well daubed, and as there is no room to spare when the latter are screwed together, the red lead is pushed through to the interior of the fitting, and there remains to cause trouble more or less serious, as the case may be. It is not uncommon, in disconnecting such joints, to find some of the smaller fittings almost entirely stopped up from this cause, and in some instances it has even been necessary to disconnect on this account alone.

Another objection to the use of lead, particularly when mixed with drying oil, is the increased difficulty of starting the thread to break the joint, on account of the extreme hardness and adhesion to the threads. If used at all the lead should only be applied sparingly to the male thread, and that far enough back from the end to make sure none of it will work through into the fitting. A much better lubricant, however, will be found in journal grease or tallow, and the latter may be improved by the addition of a small quantity of black lead, such as is used about the engine.

In screwing up the fittings it is a common practice, while holding the pipe with the tongs or pipe wrench, to turn an ell, tee or cross by inserting a bar or handle of tongs in side outlet. This is a very bad practice, as it is liable to bruise and damage the thread to such an extent as to cause leakage, which no amount of screwing up (or over screwing, rather) will prevent. Much the best plan is to screw in, by hand, a piece of pipe of proper size, of a length to give the desired leverage. And as to this screwing up, don't keep on just as long as it can be made to turn by main strength—the joint in a good thread is made long before that point is reached, and anything beyond what is necessary only tends to strain and weaken the thread, even if it does not start it to stripping or else burst the fitting. In grasping the pipe with the tongs, don't use them in such a manner as to crush in the pipe; be sure they are of the proper size and in good order, or, if adjustable, properly set. In the smaller sizes, up to 1-inch, the pipes are butt-welded, and therefore more easily collapsed than those above that size, which are made with a lap weld. Many a pipe has been split, unnoticed, by this means, and has been the cause of much trouble and expense in taking down and replacing with a new one.

PROPER ALIGNMENT.

Be sure, as the work progresses, that each added section of pipe and its socket or fitting come fairly parallel with the general line of direction. If either should be out of true by reason of a crooked thread it will be necessary to throw an undue strain on the other to bring it into line, which may result in leakage or fracture after the pressure has been turned on. It is much better to throw out any crooked parts than to risk the consequences of using them, which, in case of a steam pipe, might be serious. In connecting a union, it very frequently happens that the two parts are out of line with each other, and it is almost impossible to get the nut entered. After it is once started, however, so that the wrench can be used, it is screwed up by main strength until the gasket joint is made tight, without regard to the severe and probably dangerous strain to which it is subjected. This should never be done; always make sure that the parts are properly in line, so that they will come squarely together without depending on the nut to force them into position. If they don't line, look for the cause and correct it; don't try to overcome it. The trouble may be caused by a slight bend in the pipes, or it may be that one or both parts of the union are not tapped true. In the latter case, throw away the defective union; in the former, straighten the pipe.

In laying out the general line of pipes, both main and branches, it is frequently the case that no attention is paid to the necessity of providing for drainage. This is a very important matter, whether the pipe be used for steam or for water. If the former, it is necessary to carry off the condensation and to prevent freezing in cold weather when steam is shut off. In the latter case, it is the only means of emptying the pipe in case it is not required to be in service. This is too often a matter of guesswork, whereas it should be a matter of uniform pitch, say, ¼ inch to the foot for pipes under 4 inches diameter, and ⅜-inch for larger sizes, if so much be possible.

Each section of pipe should be provided with a firm support, so as to prevent all undue strains on the joints and connections. This is an important matter which is often neglected, and it is not uncommon to see a length of from 25 to 50 feet between supports. There is no excuse for this, except in cases where the pipe fitter cannot find (nor obtain) anything to hang to, in which event, if he has duly represented the necessity, his responsibility ceases.

USE OF UNIONS.

In designing an extensive system of piping, if at all complicated in the way of branches and connections, it may save an endless amount of trouble and expense if the liberal use of unions be indulged in. It is usual to begin at the starting point of the system, and work toward the end by adding section after section, and branch after branch, in such a manner that a trifling defect at any one point may necessitate tearing down half or more of the entire system in order to rectify it. Have a union at each point when it may be necessary to disconnect—no matter if the erecting can be done without it—it will pay in the long run, and, if properly put up, with a metallic gasket, it will give no more trouble than any other fitting.

Now, a word as to cocks and valves. It is safe to say that nine pipe fitters out of every ten will screw them on the pipe by putting the wrench (or tongs) on the hexagon or square at the end of body farthest from the pipe, and that they will use as little care in the operation as though they were handling a plain fitting—apparently oblivious to the fact that the seats require to be absolutely true to enable them to keep tight, and that they are very easily sprung sufficiently to cause leakage. In fact, a leaky valve or plug cock, if new, is invariably attributed to carelessness on the part of the manufacturer, whereas it is almost always the fault of improper handling in making the connection. It should not be necessary to say that the hexagon next the pipe being screwed is the place for applying the wrench, and a good workman is always careful to observe this point. Furthermore, the pipe tongs should never be used for this purpose, but always a wrench. If the hexagon is too large for a screw wrench, there should be a key wrench provided, as the use of tongs is almost sure to spring or crush the tapped end of fitting, and cause leakage if not breakage. With brass fittings, particularly, it is important to stop screwing as soon as it is sufficiently far to insure a tight joint, as the brass will keep on stretching indefinitely, and it cannot be made tighter than tight. With cast iron valves, &c., there is danger of bursting if screwed unnecessarily far.

FLANGE JOINTS.

In making flange joints on large pipes and fittings it is important to see that the two parts line properly and that the flange faces are parallel with each other. Being usually of cast iron, though of ample strength to resist the legitimate strains to which they are subjected, they are not strong enough to bear the added strain of the bolts necessary to force the faces together on the gasket, against the spring of the pipes caused by want of proper alignment. And on large steam pipes the danger is very serious, as the effects of a broken flange while under pressure is almost sure to cause much damage, and possibly loss of life. While there are undoubtedly many other points of more or less importance which have not been touched on in these remarks, enough has been said to point out the difference between good and bad work (and workmen). Such of the remarks as may be considered in the light of strictures on the latter class are intended to apply only to whom they apply. Every fitter, be he master or workman, can elect to which class he properly belongs, and at least will not be averse to this mention of some needed improvements in so important a branch of work as that of pipe fitting.

The collapse of the scheme for controlling the New England coal trade, conceived by Mr. McLeod, proves to be one of the most colossal failures that lately have overtaken business enterprise. It only has a parallel in the Argentine collapse, the Baring's failure, and the defeat of De Lesseps at the Isthmus of Panama. The Boston & Maine and the Reading systems, which he hoped to join together, were to be linked by two lines—the Poughkeepsie Bridge route over the old Connecticut Western (now Central & New England) to Hartford and the New England line. These two lines, while pretty far apart, in a certain sense parallel each other locally—both meeting at Hartford—and in a larger sense compete with each other on through traffic, especially as to freight. The idea of President McLeod seems to have been substantially as follows: First, to make the Poughkeepsie Bridge route the main line for through freight traffic, and, secondly, to make the New England self-supporting—in the railroad term, "wash itself." Altogether, had Mr. McLeod succeeded, he would have combined under one management more than 2000 miles of New England railroad track; and the primary object was to secure a market for the enormous coal export which the control of anthracite fields in Pennsylvania made possible.

There are now 30 steamboats navigating the Upper Congo. This indicates more rapid progress than is made by the American residents of Liberia, where years ago Mr. Scheffelin of New York erected a number of sugar mills. Recently the statement was made that the machinery from one of these mills was used in propelling a boat. The signs are that Liberia is "badly left" by settlers in other parts of the continent.

The fruit trade of New Orleans is increasing rapidly since the railroad lines in that section made a concession in their freight rates to Western points, and the local papers claim that the trade is being diverted from New York.

STOVE TRADE NOTES.

abor Troubles in Evansville Stove Foundries.

'he Stove Manufacturers' Association Evansville, Ind., which includes the iana Stove Works, the Evansville ındry Association, Kiechle, Brentano Oberdorfer and Kahn, Myerhoff & , have recently held meetings with a v to determining upon a course of ac- by which trouble with their work- ı may be avoided in the future. Ac- ding to accounts published in the local ers, differences have frequently arisen ween the manufacturers and their men, the relations have at times become so ined as to make a strike appear im- ent. It is said that recently the inters in one of the foundries ceased k and that the Manufacturers' Associa sent a letter to the mounters' union ing that all differences existing between manufacturers and their workmen be once settled by arbitration. After ting a reasonable time and no response ıg made to this letter, the members of four concerns mentioned held a meet- and agreed to close their works until difficulty was satisfactorily arranged. bearing upon the situation and show- the position taken by the manufact- rs, the firms named have issued the owing announcement:

Ve, as manufacturers, composing the ve Manufacturers' Association of Evans- e, desiring to have the people of our know the full facts, beg leave to state we append the entire correspondence tive to the trouble existing between ın, Myerhoff & Co. and their mount- After writing to the Mounters' on on February 11, 1893, that unless l mounters employed by Kahn, Myer- & Co. would return to their work by sday morning, February 13, we would e down our shops, to which notice no y was ever made by the Mounters' on, the association called another ting on February 14, and there re- ed that, in order to settle all difficul- between Kahn, Myerhoff & Co. and r mounters, a disinterested committee uld be appointed by said mounters and his association and these two commit- should agree upon the price to be l by Kahn, Myerhoff & Co. to their nters. No reply was received to this er.

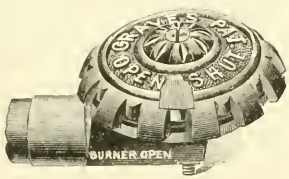
his recital of facts plainly shows that proprietors of the various foundries in nsville must pay prices fixed by the nters' Union and manufacturers are to be consulted as to what they are to pay for such work. It is a further that similar stoves to such as are in ute are mounted by mounters belong- to the same union for other foundries his city for less money, and if our busi- is to be managed by our employees the employer having no part in it, the ıer we shut down the better we fare. onsequence, at a meeting held to day he association, it is resolved to close n this evening, until the mounters will e to their senses and realize that arbi- ion is the only just way to adjust es where differences exist between loyees and employer. While it was ered by the association that the shops uld close down on the 13th, this order suspended at a subsequent meeting, as e of the parties of the association were of the opinion that the mounters, if the case were properly presented to them, would have sufficient good judgment to see that they were in the wrong, in being unwilling to meet a disinterested committee to adjust differences.

(Signed) Ed. Kiechle, Sec'y
Kiechle, Brentano & Oberdorfer.
Indiana Stove Works.
Evansville Foundry Association.
Kahn, Myerhoff & Co.

The correspondence referred to in the announcement consists of letters which passed between the manufacturers and the Stove Mounters' Union. Subsequent to the meeting of the Stove Manufacturers' Association at which it was resolved to close their works unless the strikers returned to work, it was found that the natural consequence of such action would be to throw out of employment several hundred men who were not concerned in the difficulties, and in justice to them it was suggested that the Mounters' Union appoint a committee of three to meet a similar committee from the association for the purpose of adjusting the differences at issue. This is the status of the case at the hour of latest mail advices.

Graves Gas Stove Attachment.

Eugene Munsell & Co., 218 Water street, New York, are introducing what is known as the Graves Permanent Gas Stove Attachment, as shown in Figs. 1, 2 and 3. The purpose of this device is to afford housekeepers facilities for instantly



Graves Gas Stove Attachment.—Fig. 1—Gas Burner Open.

availing themselves of the conveniences incident to the use of gas as a fuel, when for any reason a range fire is undesirable either in summer or winter. It is always ready for use and dispenses with the handling of wood, coal and ashes, and can be started or discontinued in a

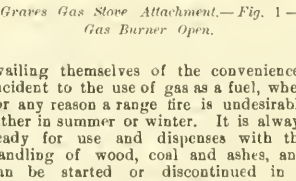


Fig. 2.—Gas Burner Shut.

moment, for the preparation of a quick breakfast or light meal. The location of the attachment is such that it in no way interferes with the regular operation of the range, while a coal fire, it is said, does not affect or injure it. The top of the range offers a suitable place on which may be placed cooking utensils that have been or are about to be used. Fig. 1 shows the burner, which is about 3 inches in diameter, open ready for lighting. Fig. 2 illustrates the burner closed and as it ap-

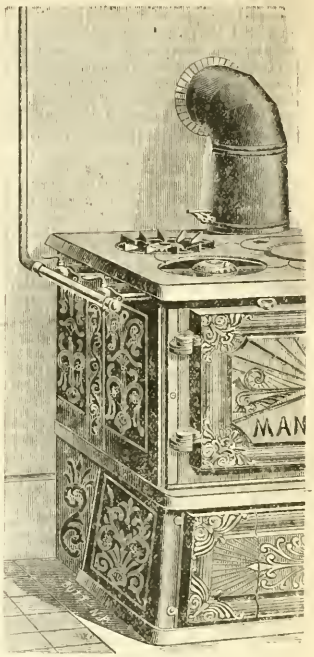

Fig. 3.—Graves Permanent Gas Attachment applied to a Range

pears when not in use, preventing it being clogged with soot or ashes from the range fire. Fig. 3 shows a portion of a range with the gas attachment applied. It will be seen that one or both burners may be used at the same time, first closing the damper to prevent the heat being drawn up the chimney. The burners are located in the center of the fifth and sixth holes, and two open-work covers are sent with each attachment, which may be used in place of the solid covers, affording better results. Baking can be done by placing a tin oven over one or both holes. The gas tube—$\frac{3}{8}$ inch—and air mixer are placed outside the body of the range and are protected by an overhanging top. The position of air mixer insures a sufficient supply of air from the outside. The makers refer to the burners as being made on the same principle as those used in connection with their Manhattan gas stoves for the past two years, regarded by them as conclusive concerning the power and economy of the burner. Under full pressure each burner will consume, they say, about 10 feet of gas per hour. The intensity of heat can be regulated quickly by turning the faucets regulating the supply. This attachment is applied to all styles of their Manhattan line of portable and brick-set ranges, and all sizes of the Home and Prize except Nos. 60, 70 and 80.

Stove Catalogues of Half a Century Ago.

Doubtless there are many readers of these columns who are curious to know what sort of trade literature was circulated among stove dealers early in the present century, and also what kind of stoves were at that time offered for sale. Through the courtesy of George H. Waldron of Chester, Vt., we are permitted to reproduce the pages of a little volume issued in 1833 and describing what was at that time known as "Stanley's Improved Cook Stove." In this little volume the construction named is illustrated and full directions for its operation set forth. We have reproduced the pages by photography and present them in *fac-simile* herewith. The first figure represents the title page, showing the appearance of the stove, while in the figures following is to be found the text of the catalogue.

We also have from Mr. Waldron a pamphlet issued in 1839 and illustrating and describing "Woolson's Improved Patent Cook Stove," made and sold at the Tyson Furnace, Plymouth, Vt. The pages in this case are a little larger than those presented in *fac simile* and carry, in addition to a description of the stove and directions for its use, a number of "certificates," as they were then called, showing what those who used the stove thought of its operation. A view of the stove and its accessories is shown in Fig. 12. After stating that more than 6000 of Woolson's Patent Cook Stoves were in use at the time the catalogue was issued, there is given a brief description of the stove, from which we quote as follows:

"A FURNACE for hard or soft coal or small fuel has been recently attached to the stove, for summer use, in such a manner as to be used in boiling and also for the baking of small bread, and that, too, with the smallest possible consumption of fuel, being so arranged as not in the slightest degree to interfere with the other operations of the stove. This alone is found to afford the advantages of an ordinary cooking stove, and when in use does not cause inconvenience by giving out heat, smoke or gas.

"A valuable improvement in *roasting* has been added to this stove which will roast meat, fowls, &c., in a more perfect and

When several boilers are in use, and it is required to make the heat more or less intense on any one of them, you are, with a stationary top, under the necessity of lifting perhaps a large boiler filled with hot water, from the hole where it was first placed, and with it displace some other boiler which must be placed over the hole from which the first was taken. And should the boilers differ in size, the holes must be suited to one or both of them, by means of circles or rims prepared for that purpose. To this trouble must be added the inconvenience of the smoke, which, during the time of exchanging boilers escapes into the room.

But with the revolving top, the object is attained by two or three turns of the crank, which brings the boilers to the position required, without the trouble of lifting them, or the inconvenience of smoke.

Boiling can be effected even at the greatest possible remove from the fire room, but the time required will be in proportion to the distance from the fire. Were the heat to be raised to a degree just to keep up the operation of boiling, and no more, at the greatest distance from the fire, the same heat would require several hours to boil water in the same situation, had it been put in

Fig. 3.—Page 4.

6

DIRECTIONS FOR USING THE ROTARY STOVE.

Regulating the Fire.

A steady uniform heat is the most desirable for cooking, as well as for heating a room. The best method for obtaining this, is to put a suitable quantity of wood into the fire room, and when it is sufficiently ignited, or well on fire, to close up the slide hearth. The sliding hearth is the principal regulator of the fire, and by a proper attention to the management of it, much may be saved in the consumption of fuel. The stove should be closed when no more heat is required than can be kept up with it in that situation, for the more air there is admitted, the more fuel will be consumed, and consequently the more heat escape into the chimney.

By closing up the hearth, the progress of combustion is checked, the blaze or flame almost ceases, and the stove is thus kept at nearly the same temperature for a number of hours, without the addition of more fuel.

During this situation of the fire, should the heat be found insufficient, it can be

Fig. 5.—Page 6.

STANLEY'S

IMPROVED COOKING STOVE.

REMARKS.

THE improvements in this stove are worthy the attention of the public—the most prominent of which, is the revolving of the top plate. This adds great value to the stove, secures many important advantages, and gives it a decided superiority over any other. The groove in which this plate moves round with great exactness, by means of a crank and cog wheel, should be partially filled with a composition of black lead and oil, which will make the movement very easy.

The principal advantages gained by the revolving of the top plate, are in the facilities it affords for equalizing the heat in the top ovens, and for obtaining at any time such a degree of heat as may be required for either boiling or stewing, and likewise in the great saving of fuel.

Fig. 2.—Fac-Simile of Page 3.

5

that situation when cold. Therefore, with a stationary top, you must take more time, more fuel, and change boilers. Whereas, with the revolving top, the time and fuel are saved and trouble avoided.

That there must be a great saving of fuel by the rotary stove, will appear to every one at first sight. The fire room is so small that a large quantity of wood cannot be put into it. The heated surface being very extensive, allows the heat to be thrown off freely in every direction. And notwithstanding first impressions are frequently unfavorable, on account of the small size of the fire room, experience has proved that the stove is sufficient to warm large rooms, and to do all kinds of cooking, even with the grate raised to the bottom of the end door, as designed for summer use.

Most families will find this stove capable of doing all the business of their kitchens, with the grate raised. And this fact, together with the advantages of the revolving plate, and the slide hearth, will so much diminish the quantity of fuel from that required for other cooking stoves, that it will be found good economy to use this through the year.

Fig. 4.—Page 5.

7

raised to any required degree, by drawing back the slide hearth. And for the purpose of making a draft only, it will seldom be necessary to draw it back more than one inch, and when there is but little fuel in the stove, the heat will be more intense, if drawn back but half that distance.

Roasting

Roasting is done in the best manner by reflection in the tin oven underneath the stove, (where it is to stand) and may at the same time be done on the front part of the stove, in the common reflector which most families have.*

Baking also is often done in this oven.—The articles to be baked are placed upon the rack which may be raised or lowered according to the space required above it. The most suitable position for the rack in *broiling, roasting, baking bread, cake, pies,* or any article that does not require to stand level, is to place the front part of the rack on the second slide from the top, and the back part of it on the third slide, giving it a small

*Front reflectors will be found very convenient in large families and in public houses, and when desired, are furnished with the stove.

Fig. 6.—Page 7.

satisfactory manner than can be done in any other way, the old-fashioned *ten foot fire place not excepted*. The oven is warranted superior to that of any other stove in use, the heat around the same being more evenly and quickly controlled than in any other stove yet introduced; for such as choose, an *elevated oven* is added and so arranged as not to interfere with the top of the stove, being quite accessible and out of the way, and equal to anything of the kind in use.

"The proprietor wishes it to be distinctly understood that the top of this stove does not revolve, its construction being such that it is the decided opinion of those who have had them in use that the boilers are at all times in *precisely the right place*.

"There is to this stove an aperture for an unusually large boiler, so arranged that the heat is applied to the best possible advantage, affording a convenience for heating a large quantity of water or for dairy use superior to any stove yet introduced; whether in *boiling*, *baking*, or *broiling*, *frying*, *roasting* or *toasting*, they have invariably proved deserving of the commendations bestowed upon them; and it is confidently asserted that no other cooking stove in the market can do so much business with so little fuel, in any given time, as 'Woolson's *Improved Patent*.'

"The TOP of this stove being large and of an even surface, with considerable space unoccupied by the boilers, adds greatly to its convenience and value. The construction and operation of this stove being such as to render the top at all times of a different temperature on different parts of its surface, so much so that while liquids are boiling in flat bottom vessels upon one part, other parts will be found to vary from boiling down to blood heat, therefore forming the best possible place to boil coffee, make tea, gravies, &c., and to place cooked dishes upon which it is desirable to keep warm until served up. Persons who have used this stove regard the convenience of the top as nearly indispensable."

DIRECTIONS FOR USE.

The directions for setting up and using "Woolson's" cook stoves are as follows:

"Place the stove on the legs according to the marks.

"If the chimney is a good one to draw, the funnel may pass into it near the floor overhead, in the same room. They draw better, however, to have the funnel go through the chamber floor, and enter the chimney as high as possible. Be sure to have the fire place closed, which communicates with the flue that receives the funnel.

In the summer season the stove may be placed near the fire place, when there is one in the room, and the funnel extended 8 or 10 feet up the flue of the chimney, or until the draft is sufficient, for perpendicular funnel always increases the draft, the fire place being left open to carry off the heat, steam, &c.

"*To kindle a fire and cook observe the following directions:*

"In order to kindle a fire quick, open both dampers, to increase the draft, having the fire and wood laid close to the front door.

"To bake, close both dampers. If the oven should be too hot draw one or both dampers partially or wholly till the heat is to your liking. As the draft of some stoves, owing to various causes, will unavoidably be quicker than others, it may be well to observe that when the draft is brisk it does not require the wood to be of a quality to produce so much blaze as when the draft is dull.

"To boil, with the greatest speed, draw the upper damper and have the lower one closed; to moderate the boiling close the upper damper and open the lower one.

"To broil, draw both dampers, open the doors, draw out coals and broil on a grid iron as before a common fire. If the draft be good it will draw the smoke into the stove.

"Whenever the oven is found not to bake so readily as when first put up, or as might be wished, the soot and ashes which have collected on and under the oven should be cleaned out with care; to do which, take off the piece of iron, which is fitted on a hole made for that purpose at the bottom of the stove, on the foreside; brush all the ashes from the top of the oven, or take them out on the top; then with the small hoe, made for that use, draw the ashes under the oven out at the

8

inclination, and thus equalizing the heat—otherwise, place it level on the third slide.

This rack will also be found the most convenient place for baking potatoes.

When the fire grate is raised, some difficulty may be experienced in baking in this oven any article that requires heat on the bottom, and cannot be turned over. To obviate this, a little fire may be kindled underneath the fire grate, which will heat the lower edge of the back plate, and consequently the bottom of the oven.

Broiling.

It is hardly necessary to say that broiling is done in the most convenient manner, in front of the stove by drawing back the slide hearth and bringing out the coals in the sink beneath it. The smoke and fumes from the gridiron, will mostly be carried up by the draft of the stove. Broiling may be done also, by placing the meat upon the rack of the under oven, or in the same manner in the common reflector, which may be used in front of the stove.

Fig. 7.—*Page* 8.

9

Boiling and Stewing.

To derive the full benefit of the fire, the boilers, stew pans, or kettles, should drop within the curb as low as may be, and not interfere with the revolving of the plate. The various sizes of holes for boilers &c., will enable families to use most of the utensils for cooking they may have on hand The boiler first to be heated, is brought by means of the crank directly over the fire, and when boiling commences, may, by the same means, be removed to give place to another, or to obtain a more moderate degree of heat, and so on, bringing up each in its turn as may be required, until all are made to boil, which may be done in a short space of time considering the number of boilers. With an ordinary fire, boiling will continue at any situation on the stove

Baking

We have already said that baking may be done in the under oven. But experience fully demonstrates, that with the advantages of the revolving top plate, it can be done under the large top oven in a better

Fig. 8.—*Page* 9.

in the sash door, and place your Tin Kitchen or Roaster opposite—at such distance as may be necessary to obtain the heat required. If proper attention is given, neither Roasting nor Baking will

10

manner, and with more ease and convenience, than by any other method ever introduced, however objectionable it may appear to some who have been accustomed to the common oven.

To prevent the articles from burning on the bottom, bricks must be placed upon the griddles, and the basins, pans, or plates, containing the articles to be baked, must be set on the bricks. To avoid the bad effect of setting the articles upon any thing cold, the bricks should be heated. This may be done by placing them on the griddles and the oven over them, fifteen or twenty minutes previous to setting the articles in. If necessary, time may be gained by turning the hot side up. At this time, also, the top plate should be turned half round, bringing the coolest part over the fire; and during the process of baking an ovenful of bread, or pies, the turning should be repeated once or twice.

The quantity of wood required for baking is so small, that those unacquainted with the stove, almost uniformly raise the heat too high, and baking is commenced too rapidly. Two or three small sticks of dry wood will make sufficient heat to bake.

The best temperature for baking is ob-

Fig. 9.—*Page* 10.

11

tained with the draft closed, as described under the head of directions for regulating the fire.

When baking is in operation, care must be taken not to remove the cover of the oven too frequently, or keep it off long—and should the oven be too hot, the cover must not be taken off for the purpose of cooling it, but the end door of the fire room may be thrown open.

The small round oven is used in the same manner as the large one, for all kinds of baking, and it is to be set over the largest boiling place.

The plate, pan, &c., used in it, should not be so large as to prevent the heat ascending freely all around it, for on this depends the baking of the top.

The proper degree of heat for baking may be very correctly ascertained, by placing the inside of the hand upon the top of the oven, which should be so hot as to be rather above what can be borne.

Those who have the care of baking, are often too anxious to see the bread begin to brown. With a proper temperature of the oven, this appearance will not commence in loaves of ordinary size, until about twenty-five or thirty minutes after they are set in.

Fig. 10.—*Page* 11.

12

Heating Flat Irons.

For this purpose a sheet iron flat heater accompanies the stove, suited to the largest aperture.

Fig. 11.—*Page* 12.

STOVE CATALOGUES OF HALF A CENTURY AGO.

hole above mentioned. Lastly, replace the piece of iron in the hole as before.

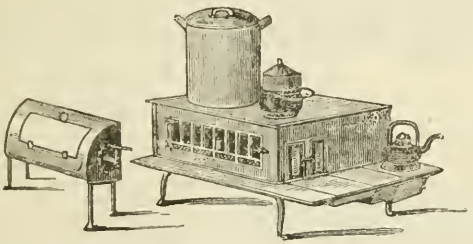
"To ROAST, put on the Sash or Mica Door—make a fire of chips or small sticks laid along the side, near the small holes interfere in the slightest degree with the other operations of the Stove.

"To put the Furnace in operation, draw the slide at top about 1 inch, and box at bottom, so as to open the grate, on which

place fire and coal or light fuel. By the use of light fuel, to make a brisk fire, small bread can be baked in the oven of the stove from the heat of the furnace. When the furnace is not in use, the slide at top and box at bottom should be returned to their places to close the draft."

Wrought Iron Range Company.

We are indebted to the Wrought Iron Range Company, St. Louis, Mo., and with branch factory at Toronto, Canada, for a copy of a catalogue which they have just issued relating to the Home Comfort wrought steel ranges and hotel kitchen outfits. The volume is of large and, it must be confessed, unwieldy size, measuring 10 x 14 inches, and consists of 124 pages of letterpress profusely illustrated. The paper is of a good quality and the printing clear and sharp. The first leaf of the volume carries a view of the general offices, salesroom and factory in St. Louis, and also of the company's works at Toronto Junction. The title page informs the reader that in addition to Home Comfort wrought-steel cooking ranges, the company manufacture French ranges and complete kitchen outfits; steam tables, laundries, carving tables, urns, ovens, &c., adapted to meet the requirements of hotels, restaurants, private dwellings, public institutions, dining cars, steamboats, railroad camps, army posts, &c. With regard to the Home Comfort steel ranges, the company state that these goods are now known and designated by numbers in place of letters, thus making it more convenient and definite when either ordering ranges or repairs. During the past year many prominent changes have been made, and the general style of the goods, as well as the finish and appearance, improved. The ovens have been enlarged, making them nearly square; all parts and pieces subject to strain are made of malleable iron and wrought steel, while their malleable water backs for either hard or soft coal are tested to 180 pounds. Other features of the Home Comfort goods include patent triplex grate so constructed that clinkers cannot form on it. The grate bars for the hotel and restaurant ranges are so made as to be easily removable when cleaning out the fire box or making repairs. The front of the doors and ash-pans are polished flat, leaving no open spaces as receptacles for grease and dirt, while a finished and handsome appearance is given to the ranges by fitting them with nickel-plated brass protecting bars in front. The end flues of the ranges are lined with asbestos, which tends to retain the heat where it is most desired. Reasons are given why Home Comfort ranges are superior to stoves, and throughout the entire volume is to be found much of interest and value to those desiring goods of the description named. The illustrations cover a wide variety and show the goods described to advantage. A long list of hotel ware and culinary appliances, together with coffee and spice mills, hotel cooks' and butchers' cutlery, &c., constitute features of interest. One page is devoted to directions for ordering Home Comfort ranges, while another is devoted to directions for ordering repairs for them. A long list of references and testimonials occupy several pages at the close.



Stove Catalogues of Half a Century Ago.—Fig. 12.—Woolson's Cooking Stove.

ODD PLATES.

THE WELLS MFG. COMPANY, Greenfield, Ind., send us a copy of a very attractively printed circular which has just been issued from the press. In entering upon the second year as manufacturers of Model stoves and ranges, the company state that it has been their aim to keep their line up to the highest standard of excellence, and that they have added many new features during the past season. At the present time they are engaged in the preparation of several handsome patterns, which will appear from time to time. Their shops are equipped in every department with the latest improved machinery and tools and manned by competent workmen. The Model cook stove is designed to meet modern requirements for a stove possessing liberal dimensions in all essential parts, while operating with a minimum consumption of fuel. The stove is shown by means of well executed engravings, and is adapted for burning coal and is also made for wood. The company make under the same name a four-hole range for coal and several varieties for using wood as a fuel. The Model Oak is a neat, medium priced construction provided with the modern features. The Model Gas is a handsome Franklin stove, with fire-clay deflector, which is said to add greatly to its heating capacity. It is supplied with a burner or draw center grate, as may be desired. Fire-clay linings, above the fire bowl, are provided as a protection to the sides and back. The stove is ornamented with nickel and art tile, but is also made in plainer designs.

THE PORTLAND STOVE FOUNDRY COMPANY of Portland, Me., send us a four page circular, telling how to manage coal furnaces and hot water heaters. One page is devoted to an illustration of the Atlantic coal furnace, and also to water section, as placed in the furnace for the purpose of making a combination furnace. Another page illustrates the triangular grate used in connection with the heater.

THE BRADFORD STOVE COMPANY is the name of a concern recently incorporated at Chicago, with a capital stock of $100,000. The incorporators include Francis Jackson, Thoman P. Paxton and Arthur C. Conway.

THE PHILLIPS & CLARK STOVE COMPANY of Geneva, N. Y., are the subject of an illustrated article in the Troy *Daily Times* of February 26. The works are briefly described, reference being made to the number of men employed, the capacity of the plant, shipping facilities, &c. The article is illustrated with excellent likenesses of George H. Phillips, one of the pioneers in the stove trade, his connection with the business covering a period of fifty years, and of Walter A. Clark, who is treasurer of the company. Mr. Phillips has personal supervision of every department and carefully watches the construction of the Andes goods from beginning to end. He was born at Brunswick, N. Y., in 1816, and at the age of 18 years went to Troy, where he learned the carpenter's trade. In 1852 he identified himself with the firm of Davy, Anthony & Co., which later became Davy, Ingrahm & Co., who were in turn succeeded by Ingrahm & Phillips, and still later by Ingraham, Phillips & Co. In 1868 he retired from this firm and founded the stove business of George H. Phillips & Co. In the following year Walter A. Clark was admitted to partnership and in 1882 the name was changed to Phillips & Clark. In 1885 the firm removed to Geneva and were incorporated. Mr. Clark, the treasurer of the company, began his early business career with J. M. Warren & Co., where he remained until he engaged in the business of stove manufacture in 1869, when he and his father-in-law, Mr. Phillips, formed a copartnership. Mr. Clark has looked after the commercial side of the business, which has grown to large proportions.

THE NEW BUILDINGS of the Scranton Stove Works are being pushed forward as rapidly as circumstances will permit. William R. Williams, the contractor, has a large force of men engaged, and we understand that a portion of the superstructure has already been raised. It is the intention of Mr. Williams to have the contract completed by the first of May.

THE CHICAGO & ERIE STOVE COMPANY of Erie, Pa., favor us with circulars of their four-hole range, which is made under the name Modern Helper. It is a cast-iron construction with steel range improvements, which the company refer to as good selling points. The oven is 18 x 20 inches, and has steel bottom oven plate, making it a quick baker. The oven door is so balanced as to open easily, and when dropped into a horizontal position forms a convenient shelf. The Modern Helper is made with four No. 8 holes, and also with four No. 9 holes, and can be furnished with or without high shelf, high closet, reservoir and water front. Brick linings are made for hard and iron linings for soft coal.

IN A NEATLY PRINTED 16-page pamphlet, bound in colored paper covers, which has just been issued, is a brief sketch of the life of William Westlake, for many years prominently identified with the stove board business. The pamphlet is dedicated to the young men of America, and carries as a frontispiece an excellent likeness of Mr. Westlake.

THE TOLEDO STOVE COMPANY is the name under which the stove foundry business, heretofore conducted by Jacob Leonard & Co., has been incorporated. The new concern have been organized, we understand, for the purpose of increasing the capacity of the present plant, sufficient capital having been put in the business to warrant the establishment of improved and increased facilities in the manufacture of stoves. The directors met on February 13 and elected George G. Metzger president, Jacob Leonard vice-president and general manager, and Theobald Shunk secretary and treasurer.

WE UNDERSTAND that the Eclipse Stove Company of Mansfield, Ohio, have recently increased their capital stock from $60,000 to $100,000.

THE MAGEE FURNACE COMPANY of Boston, Mass., are distributing a very neat advertising novelty in the shape of a pocket barometer, which, upon exposure to the weather, is claimed to indicate the atmospheric conditions likely to exist in the near future, by the varying color of these spots in the center. It is known as Dessau's Pocket Barometer and consists of a disk 1¼ inches in diameter and one-eighth of an inch in thickness. Upon the back of it is the inscription, "Magee furnaces, ranges and stoves are warranted to please." In the same box containing the barometer we find a handsome nickel-plated match box which, without directions, is somewhat of a puzzle to open. Upon one side of it is the name of the company and their various addresses, while upon what may be designated as the top of the match box is the inscription "Magee furnaces, ranges and stoves are the best." The match box is got up in a very neat manner, is highly polished and is likely to prove not only useful to the recipient, but will serve to keep constantly before his attention the name of the company sending it out.

THE CLEVELAND FOUNDRY COMPANY of Cleveland, Ohio, have just issued from the press an attractive pamphlet of 48 pages, constituting a catalogue of the specialties manufactured. Attention is given to oil and gas heating and cooking stoves, registers, sad irons and hardware specialties. The goods are profusely illustrated, and, in connection with descriptive letter press, afford ample opportunity for the reader to gather a comprehensive idea of the merits claimed by the manufacturers. The list of stoves shown include the Puritan, Chief and Triumph lamp stoves; the Paragon and Banner oil stoves, and the Banner gas stove. The design of the front cover of the pamphlet is largely typographical in character, while the fourth page carries a *fac simile* of the company's trade-mark. There is also shown a bird's eye view of the company's office and factory at Cleveland. The cover bears the imprint of Gies & Co., Buffalo, N. Y.

A NOVEL HEATING APPARATUS very much resembling one of our open grate fires has been patented by Philippe Mancheron, Nevers, France. The construction of the device is such that the inventor claims to be able to use different combustibles at the same time, thus securing efficient combustion and utilizing a poor quality of fuel.

A CIRCULAR illustrating the Reliable gas ranges reaches us from Hughes & Stephenson of 747 Craig street, Montreal, Canada, who are agents for these goods in that section. The range is shown with water heater attached and connected with a circulating boiler. The size of the heater is 21 x 11 inches at the top and is 7½ inches in hight. It is operated by two separate burners, which permit of cooking operations at the same time the water is being heated.

THE AMERICAN OILGAS COMPANY of 44 Hanover street, Boston, Mass., refer to the Standard Gas Generator, which they manufacture, as being adapted for use in connection with any stove or heating apparatus. It is claimed to generate gas from kerosene oil and to operate at a very small expense, without smoke or odor.

THE ECLIPSE STOVE COMPANY of Mansfield, Ohio, are offering their Brilliant Eclipse in two sizes and adapted for burning coal and wood. It is of good design, has four boiler holes in the top and embodies the latest improvements. W. H. Peckham of St. Anthony Park, Minn., is agent for the company's goods in Minnesota and North and South Dakota.

THE MILLER GRATE COMPANY, with office at 100 Euclid avenue, Cleveland, Ohio, send us a very attractive catalogue of the Miller patent reversible shaking and dumping bar and curtain grate which they manufacture. The pages, which are oblong in shape, are bound in covers by means of metal fasteners, which can be readily removed. The object of using these fasteners is to allow sheets of new designs to be inserted as they are issued by the company. The line of goods illustrated embrace a large number of handsome designs, which are printed on tinted paper in such a way as to form with the black ink in which the engravings appear a striking contrast. The latter portion of the volume is in the nature of a supplement for this year, and gives a number of designs of adjustable summer pieces and open grates, together with descriptive particulars and dimensions as to hight and width. The latest addition to the company's assortment is the Sun gas fire place, which so distributes the gas over the fire place as to make a bright and brilliant fire with intense heat. The parts are so arranged that it is said to be impossible to light at the mixer if properly arranged.

THE PENINSULAR STOVE COMPANY'S Chicago house have brought out an envelope of new design, which must prove an attractive advertisement to everybody through whose hands it passes. The trade-mark is shown on the left side, with raised letters. Back of the trade-mark is a partial view of the sun, whose rays form a halo round the design, fading into a light blue tint, extending over the remainder of the face of the envelope.

JAMES BOYLE & Co. of Salem, Ohio, send us a calendar printed in two colors for the month of March. The card is embellished with an illustration of the prize Keystone four-hole cook stove, below which appears the days of the week and month. Below this in turn is the inscription. "Look for us April first." The statement is made that Frank A. Peterson & Co. of Minneapolis, Minn., are agents for the company's goods in the Northwest.

ARRANGEMENTS have recently been perfected whereby Charles King, secretary of the Union Iron Works & Mfg. Company of Denver, Col., has secured for his concern the control of the New Idea warm air furnace in the Western market. The New Idea furnace is the property of Schill Bros. of Crestline, Ohio, and we understand that Mr. King's concern agree to manufacture at least 500 furnaces the first year, and not less than 1000 each succeeding year. The local papers state that a shop right of $2500 was paid by the Denver concern and that they will also pay a royalty of $4 on every furnace which they manufacture. The works of Schill Bros. in Crestline, Ohio, are now busy getting out patterns for the Union Iron Works & Mfg. Company. Mr. King is reported as expressing the opinion that the New Idea furnace is not only satisfactory, but far surpasses his most sanguine expectations, and that his firm would place the furnace among the trade on the Pacific Coast before the close of another year.

WE ARE INDEBTED to Fletcher, Russell & Co., Limited, Warrington, England, for a copy of an interesting volume relating to gas-heating and labor-saving appliances. It is a volume of 120 pages, profusely illustrated, and covers a wide range of gas-burning constructions manufactured by the concern named. These goods, as might be supposed, differ in some particulars from the gas ranges turned out in this country, a noticeable feature being the arrangement for baking and broiling. The bake oven is closed, very much like those in coal and wood stoves, while the broiling is done on top, there being a drip pan placed just beneath the broiler for the purpose of catching the drippings. Some of the ranges are made of galvanized iron and all parts interchangeable. Some have open roasters and others divided ovens, in which all roasting, broiling and toasting is done under the burner in the lower oven. Another feature of some of the goods turned out by this concern is a plate warming arrangement on both sides of the stove. The volume gives attention to a varied assortment of burners and also to gas-heating stoves. A great deal of interesting matter relating to gas-burning appliances is also presented, together with illustrations of crucible furnaces, condensing stoves, hall-table stoves, chancel stoves, &c. While the volume is devoted exclusively to goods of English manufacture, there is a good deal in it that is likely to prove of interest to American readers.

THE SUPERIOR FURNACE COMPANY of Little Falls, N. Y., have just placed upon the market a new steel range of pleasing design and embodying attractive features which they feel confident cannot fail to be appreciated by the trade generally. It is finished in a careful manner and the ornamentation, considered as a whole, is of a character to please the eye. The range is made under the name Superior and has large flues which facilitate combustion, a free draft insuring an even and steady heat to the oven and making the stove a rapid and satisfactory baker. All the flues are lined throughout with heavy asbestos board. The ovens are thoroughly braced to prevent warping or buckling, while the joints are so riveted as to allow of an equal contraction and expansion of the metal, which the manufacturers state is of the highest grade of cold rolled open-hearth steel plate. The only cast iron used about the stove is in the fire-box linings and the top cooking surface. The general proportions, sizes and dimensions of the oven and cooking surface have received careful attention at the hands of the company, and the stove is placed upon the market in the confident expectation that it will meet with a large sale and rapidly become popular with the trade wherever introduced. No little attention has been devoted to the ornamentation and the manufacturers feel that the Superior will prove one of the most attractive steel ranges which has been placed upon the market. A feature of the decoration is found in the nickel corners and the adjustable bars at each side of the stove. The high closet and shelf are convenient and unique. The warming closet door has roll top, while the other doors are so made as to drop down, the oven door forming a convenient shelf when open. In the production of this range durability has been one of the objects in view on the part of the manufacturers. The Superior is now made in four sizes, and is brought out to supply a large and well-defined demand made upon the company by their larger customers in the Western cities, where this class of goods is very popular.

GEORGE W. GRAVES, sales manager for Eugene Munsell & Co., 218 Water street, New York, attended the inauguration today at Washington as one of the delegates from the Cleveland & Stevenson Iron and Metal Club.

SCHILL BROTHERS, Crestline, Ohio, are bringing out a line of open-front heating stoves for either soft coal or slack fuel. The new heater will embody all the principal features so successfully used in their New Idea hot-air furnace, and will, it is claimed, consume the smoke arising from the fuel used, being gas-burning in principle. The fire pot consists of an inner cast-iron receptacle, with a series of openings near the center and corresponding openings at the top. This cast fire pot is surrounded by a steel jacket, with an air space between, into which air is admitted

and thoroughly heated before reaching the fuel. The outer steel jacket, with air space between, prevents the same from becoming red hot. In addition, the construction of this stove is such as to cause the fuel to continually burn through its center and away from the casting or lining. Two cast-air ventilating ducts are provided, one at each side, back of stove front.

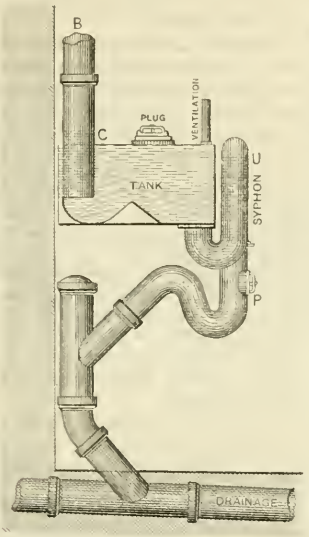
One of the German papers contains a very entertaining account of the roasting of a whole ox by means of gas on the occasion of some festivities at Hanau not long since. The account states that the roasting chamber was made of sheet iron 3.2 meters long (10 feet 6 inches), and 2.4 meters (7 feet 10½ inches) wide, and of sufficient hight to permit the ox to be placed within on a spit. The latter was turned from the outside by suitable gearing. The carcass was strongly trussed by screwed skewers and iron straps so as to hold it together. A perforated pipe ran above and parallel to the spit, terminating outside in a funnel at each end, for the purpose of basting the meat, and there was a suitable dripping pan underneath it. The roasting apparatus was separate from the casing, and consisted of a wagon-shaped frame work of gas piping. The two semicircular ends of this frame work were made of 2-inch pipe, connected by 16 longitudinal pipes ¾ inch diameter, eight on each side, the two lowest being set inward so as to throw some heat underneath the carcass. These pipes carried 448 burners in all, and the gas, measured by a 100-light meter, was connected to both ends of the frame work, so as to insure regularity of burning. The whole affair was got up with an eye to effect, the oven being inclosed in a shed fitted up with carving and serving benches, and surmounted by a colored lantern with the words "Cooking by Gas." The ox weighed 650 pounds as trimmed for roasting. It was killed six days before being cooked, flavored with 3 pounds of pepper and 15 pounds of salt, the back covered with parchment paper, and roasted from 9 in the morning till 3.30 in the afternoon, with a consumption of 300 cubic feet of gas. The cookery seems to have been a great success, the meat being described as "extraordinarily savory, tender and juicy." In an hour and a half from the time the carving commenced nothing but the skeleton remained.

"The latest thing in penny-in-the-slot machines," says the English correspondent of a contemporary, "is one for the supply of food, drink and even articles of dress. It is on view now in London, and the writer was shown how tea, coffee, aërated waters, and malt and spirituous liquors were supplied by it. The tea and coffee is delivered hot. There are also machines for dispensing to the public fruit, cakes and the like, and others are adapted for supplying handkerchiefs to those who have left home without that useful article, and collars and cuffs for those who may desire a change in the middle or at any time of the day. There is something rather funny in the idea, but the whole scheme seems to be practicable, and the machines are very ingenious in their construction."

The argument is advanced, not without some show of reason, that the increased amount of cotton, wheat and other commodities now being carried by speculators, as compared with one year ago, is the direct result of an abundance of money, loans being obtained for this purpose much more easily than in some former years. The excess of cotton now carried in stock is 534,000 bales, compared with last year at this date, and of wheat 40,000,000 bushels. The former item alone represents $24,000,000. Instead of borrowing, speculators would find it more advantageous to sell if money was not so easy.

Water-Closet Flushing Apparatus.

A correspondent of an English building exchange, writing from Paris, comments upon the drainage system of the French capital and the difficulty experienced in flushing its drains with the least possible waste of water, owing to the scanty supply of that element possessed by the city. Incidentally he describes an ingenious apparatus adapted for this purpose, the invention of a Monsieur Laffargue, which has recently been approved for adoption by the Municipal Council of Paris. The device is stated to work very satisfactorily. Though it can hardly be called a step forward in the science of sanitation, the adoption of some such contrivance is rendered absolutely necessary in Paris while water is so scarce. We present herewith a drawing of the apparatus, together with a description, which may be of interest, as showing the principles of sanitation pursued abroad.



Flushing Apparatus in Use in Paris.

The apparatus works automatically by means of compressed air, and, according to the inventor, will save nearly 70 per cent. of the water now wasted in drainage of water closets. The apparatus is exceedingly simple in arrangement, and, what is a great thing in the eyes of house proprietors, may be adapted to the system of closets at present in vogue. The down pipe B falls into a tank, as shown in the sketch, of general dimensions about 20 x 16 x 14 inches. This tank, which is hermetically sealed, is furnished with a syphon of large diameter (5 inches). The tank is fed by a service pipe of very small diameter, allowing a very small quantity of water to gradually fill the tank. Rain and slop water may also be allowed to run into the tank. The soil, &c., falls by the down pipe into the tank, and there mixes with the water contained in the tank. The air in the portion of the syphon between U and P is compressed to a more or less degree. As soon as the level of the water in the tank attains the point C the air in the pipe between U and P becomes compressed to a great degree, and this pressure overcoming the water seal P, forces the water into the drains, and starts the syphon U, the whole contents of the tank being rapidly and forcibly drawn away into the drain pipes. This takes place each time that the water attains the level C.

All Chicago Tracks to be Elevated.

Persistent agitation against grade crossings by steam railroads in Chicago has at last borne definite fruit. The city council, on the 23d ult., by a unanimous vote, passed an ordinance to compel every railroad company operating tracks in the city to elevate them within a specified time. The city is divided for this purpose into three zones. The heart of the city forms the first district, within which the work of elevation must begin not later than July 1, 1893, and be completed by January 1, 1895. Very little mileage lies in this section. The second district is important, covering a zone which includes the terminals and a considerable length of track of every road. Work in this district is to begin not later than July 1, 1895, and be completed by January 1, 1897. The third zone takes in the suburban districts of the city, and work must there begin not later than July 1, 1897, and be completed by January 1, 1899. Regulations have been carefully provided to cover the character of the elevated roadbeds and their minimum hight above the street grade. The roadbeds must be supported by girders of iron or steel, on iron or steel columns. The minimum hight prescribed is 16 feet above grade.

The penalty provided for violation of the ordinance is ingenious. Not only are all tracks remaining at grade after the specified time declared to be a nuisance and to be removed and abated by the Commissioner of Public Works, but also the crossing of a street at grade by a locomotive or car is declared unlawful and every such act is a nuisance, finable in the sum of not less than $100 nor more than $200.

The railroad interests of Chicago are so vast and the burden imposed upon them by this action of the council is so great that at first blush it would seem too stupendous a task to be successfully carried through on the lines laid down. The elevation of all the tracks of steam roads now entering Chicago, if elevated over their present roadbeds, would cost an enormous sum, perhaps beyond the ability of any but the very greatest railroad financiers to raise. It is estimated that in the case of some of the roads an investment equivalent to one-fourth or more of their entire share capital would be necessary. Their side tracks and connections with factories along their line would have to be raised as well as the extensive yards which nearly all possess within some part of the city limits. To such a pitch, however, has public opinion been aroused on the subject of grade crossings, in consequence of the increasing number of fatalities, that the railroad companies and the manufacturers who will be affected were not able to influence a single vote in opposition to the ordinance. It had been in course of preparation for a long time and all its provisions were very thoroughly considered before it was put upon its passage.

Now that the railroad companies are obliged to face the inevitable, busy brains will be put to work on plans which will accomplish the purpose with the least expenditure of money. It is probable that yards for the storage of freight cars will be gradually removed outside the city limits, to reduce the number of tracks to be elevated. It is further probable that more roads will unite in the construction of depots and terminal facilities than hitherto, and that the Torrence scheme of track elevation and terminals will be greatly amplified. The opportunity now exists for the display of the highest engineering talent and business ability in systematizing and concentrating the intramural railroad traffic of Chicago, so as to bear with as little burden as possible on individual roads. It is a great problem, but now that it is to be taken resolutely in hand a way will doubtless be found to carry it through in spite of the formidable financial obstacles apparently darkening the way.

TRADE REPORT.

The Iron Market.

There have been no developments in the Iron market during the past week which are particularly encouraging, for while demand is on the increase, prices do not hold their own, but slight concessions are made to secure orders. There has been no decided change in the situation of the market, and taken as a whole the market seems slightly irregular, the firmest holders of Pig Iron being disturbed more or less by the low quotations made on Iron in which Mill Cinder figures prominently and on the product of furnaces whose owners are not strong enough financially to withstand the pressure incidental to an accumulation of supply on a quiet market. In reviewing the Iron business for the past month for the Eastern portion of the country, it may be said that all the business that had been figured on has become actual orders in hand, and yet there is extreme depression. It is difficult to account for this feeling, as the volume of business is large, larger probably than at any previous time; the only rational explanation seems to be that the capacity for production has increased even more rapidly than consumption. The shipyards never had so much work in hand; the locomotive works are running full time with over 4500 hands; bridge builders are doing well; the large engineering and machine shops are working to full capacity; manufacturers of saws, files and hardware specialties are doing their full share, while the stove and heating trades never had so large a business, and yet complaints of unremunerative business are met with on every hand. Improved methods of construction and manufacture have done much to increase the producing capacity and to cheapen cost, but there are so many complaints that there must be some basis of truth in the claim that prices are too low, and if there is, it is hard to see how to get around it. The only chance for any radical improvement in the Iron and Steel trades is a heavy demand for Rails, and of that there is no immediate prospect, and, as a matter of fact, such a movement in large proportions is not likely to occur until conditions change very materially. With a capacity of from three to four million tons per annum, there is no reason to apprehend scarcity at any time within sight, consequently the roads only order such lots as are required from month to month. Hence, while there are no great spurts of activity, neither are there any periods of very serious depression, and for these reasons no very extraordinary demand for Rails is figured on. The development of the electric railroad systems may help the mills out, and some hopes are entertained of an export trade, but both of these factors, if we may use the expression, are at present in the future.

To summarize the entire position, however, it may be said that there is plenty of business, but it is done at unremunerative prices, due to too rapid an expansion of productive capacity.

In Western markets the month of February, in point of volume of the Iron business, showed considerable improvement over January. Prices, too, on some lines of both raw and finished material were better during the month just closing than in January. Steel is in fairly good demand. Structural Material, Plates, Bars and Wire Nails are in better demand, without any better prices, except on Wire Nails. Pipes and Tubes are in fair demand, but prices are somewhat demoralized. Taken as a whole, the condition of business as we find it on March 1 is fairly satisfactory as far as demand is concerned, and while prices have improved in some directions there is much room yet for further betterments.

In Pig Iron, buying has again assumed the hand-to-mouth character which prevailed so largely before the sharp advance came in the middle of February. The principal reason for the falling off in demand is the fact that several large Steel makers in the Pittsburgh and one or two in the Wheeling district, who came into the market at about the same time as buyers of metal, have satisfied their requirements and may possibly be sellers before long. In regard to the future, the impression prevails that prices are not likely to go higher for a time, in view of the limited demand, and also on account of reports of sales of Ore at even lower prices than prevailed during the latter part of 1892. Production has been increased to some extent by the blowing in of several furnaces in Pittsburgh during the month.

In and about Chicago the business in Pig Iron for February is stated to have been the largest ever done in one month. Consumers are generally realizing that prices are as low as they can expect them to go and orders for long deliveries have been more frequent of late than for two or three years past. Cases are frequent in which purchases have been doubled after the situation had been carefully pondered. The more satisfactory condition of the makers has led to a slight improvement in prices and changes are therefore made in our quotations to correspond with the firmer feeling. A better trade is reported in Southern Coke, the buying being more general. Large contracts are not numerous, the orders running for moderate lots for comparatively short deliveries. Further cuts are reported in prices by the leading Southern companies, and the market can hardly be called strong. On the other hand, the Southern market continues to show additional weakness, and it now seems impossible to predict when the downward tendency will be checked. Each sale reported seems to have been made at a shade lower than the previous one, and, in the absence of any large buying, the market is in a position to be forced down even lower. As an evidence of the voracious appetite of the furnaces, the placing of an order for 1000 tons of No. 1 Soft and Gray Forge by a car works last week is an indication. To secure this order, nine agents offered their figures, and, of course, the lowest-priced Iron was ordered. It is claimed that the price at which the Iron was bought was the lowest yet made, and in consideration of the fact that nine agents were after the business, it can readily be believed that no fancy price was obtained.

In the New York market some brands of Pig Iron bring full former prices—that is, the basis of $15 for No. 1 Extra Foundry—but concessions of 25¢ @ 50¢ ℔ ton are not infrequent. We quote Northern brands at $14.75 @ $15.25 for No. 1; $14 @ $14.50 for No. 2, tide-water. Southern Iron, same delivery, $14.75 @ $15 for No. 1; $13.75 @ $14 for No. 2 and No. 1 Soft; $13.25 @ $13.50 for No. 2 Soft.

Pig Iron prices have not changed either for better or worse in the Philadelphia market. There is a full supply of Iron of one kind or another, and for the kind that is not specially wanted prices are inclined to be weak and irregular. Standard brands are well taken care of, and holders have no difficulty in sustaining prices, and to that extent the market may be called steady; but the feeling is not sanguine, and sellers seem to think they are doing pretty well to stave off concessions. The present market is a waiting one, and until something occurs to give it a new turn the range of prices will probably be as follows for Philadelphia and equivalent deliveries, with 25¢ to 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$17.00	@ $17.25
American Scotch, No. 2X.....	16.00	@ 16.25

In the Pittsburgh market the quotations remain unchanged, although on others than Foundry brands it is admitted that prices would be shaded under favorable conditions. We quote as follows:

No. 1 Foundry.....	$13.75 @ $14.00,	cash.
No. 2 Foundry.....	12.75 @ 13.00,	"
Charcoal Foundry No. 1....	17.00 @ 18.00,	"
Charcoal Foundry No. 2....	16.50 @ 17.00,	"

Reports from Chicago indicate that local Coke Iron is still moving quite

freely, with additional business in sight. The very large sales made within the past six weeks have put the manufacturers here in very good condition. The competition for business has thus far been confined to the smaller companies and it remains to be seen how long the larger ones will refrain from pressing their attention on consumers. Lake Superior Charcoal is quiet but firm. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50 @ $17.00
Local Coke Foundry, No. 1	13.25 @ 13.75
Local Coke Foundry, No. 2	13.00 @ 13.25
Local Coke Foundry, No. 3	12.75 @ 13.00

In the South it is difficult to see anything very encouraging in the future, and it now looks as if prices will make a record that has never yet been reached. We quote as follows for cash, f.o.b. cars St. Louis:

Southern Coke, No. 1 Foundry,	$13.75 @ $14.25
Southern Coke, No. 2 Foundry,	12.50 @ 12.75
Southern Coke, No. 3 Foundry,	12.00 @ 12.25
Missouri Charcoal, No. 1 Foundry	13 50 @ 14.00

Billets and Rods.—Neither domestic nor foreign products have met with freer sale, and the market remains in somewhat unsettled condition, with prices still leaning somewhat in buyers' favor.

Steel Rails.—In this market few and only small contracts have been placed during the past week. To all accounts 5000 tons will cover the entire business.

Metal Market.

Copper.—The market is weaker, if anything, than it was at the date of our last review. In any event, offers to sell at prices that appeared to have been exceptionally low a week ago are now common, and the demand drags along wearily, with little indication of immediate improvement. In fact, the purchases by consumers appear disappointing thus far this year, and the comparatively light movement serves, in a measure, to offset the intended effect of the reduction in output. For the present, the appearances are that improvement prior to the opening of navigation is improbable, since consumers are disinclined to buy ahead, except at prices a round fraction below those generally asked. Export demand is extremely slow at the moment.

Pig Tin.—Speculation as to an extra session of Congress and action upon the matter of abolishing the duty prescribed in the McKinley Tariff law has kept a lively interest in the market and served to cause somewhat violent fluctuations in the prices here and in Europe. Up to the present time the indications are that more "short" interest has developed in Europe than on this side of the Atlantic, and it is a remarkable fact that spot stock has, during the past few days, commanded a premium in this market, while the margin between spots and futures has widened in London to about 7/6.

On Tuesday, February 28, the House of Representatives, on motion of Chairman Springer of the Ways and Means Committee, passed the bill repealing that section of the McKinley bill which imposes tax of four cents a pound on pig tin after July 1 next. The bill is expected to go to the Senate in a few days, when it is supposed it will be put through without opposition.

Pig Lead.—Under the influence of freer offering for March and April shipment from the primary sources of supply, and apparent indifference about buying on the part of consumers, the market has weakened a trifle. Production has been somewhat larger of late, and the prospects are that there will be a further increase as soon as weather conditions permit.

Spelter.—Heavy production has sufficient weight to keep smelters anxious for orders for future shipments. Sales have been fair, chiefly for April and later shipment, but not liberal enough to have any pronounced bearing upon the market.

Antimony.—Outside of ordinary jobbing distribution there has been little movement, and prices have varied to a moderate extent only.

Tin Plate.—The demand for future deliveries has fallen off to comparatively small proportions, and business contrasts distinctly with that executed during the week preceding the one under review. Spot transactions have been of commonplace character, moderate, all told, and chiefly at old prices. Supplies here are only fair, and the assortment, particularly of full weight Cokes and Charcoal Ternes, is still rather poor. While the amount of business that has been done in Tin Plates during the past month is considered fair, the demand has been limited. But little, if any, outside work has been done owing to snow and storm, and the lack in demand has had a tendency to weaken the price on some grades of Terne Plates.

Coal.

In the Anthracite Coal trade the general situation is confused and uncertain, owing to the Reading troubles, but prices are not affected. The combine schedule still holds good and is closely followed by the independent outsiders, so that one of the largest of the latter remarks that no sales below are heard of. At the same time Coal is in good supply, and the recent scarcity of small steam sizes is hardly felt any longer. Lehigh Pea is $2.40 and Free Burning, $2 65, f.o.b.; Buckwheat, $1.85 to $2.35, according to quality.

The quantity of Coal moving out for consumption is large. The effects of the Reading rupture are seen in the feeling of uncertainty respecting the future, there being little disposition to buy except from necessity. There is a general understanding that spring prices will drop April 1 to a minimum, the plan being to work up gradually by a succession of advances through the season. The basis, however, both for Anthracite and Bituminous is higher than it was a year ago, say $1 average for the former and 25¢ for the latter. Railroad tolls for Bituminous will be advanced 25¢ @ 50¢ per ton April 1, the Baltimore & Ohio and Pennsylvania having already given notice to this effect. The final outcome of the Reading situation nobody pretends to know. It is assumed that the Lehigh Valley will stick to the combine whatever happens in New England. The Jersey Central is out to stay. Competition by the railroads to obtain Coal transportation is therefore not improbable. At Tuesday's meeting of agents nothing was done.

The total shipment of Anthracite Coal for the week ending February 18, as reported by the several carrying companies, was 840,606 tons, an increase of 57,828 tons, and for the year to that date the total tonnage has been 5,267,030 tons, an increase of 129,595 tons over last year.

Financial.

The failure of two or three large iron concerns in Pennsylvania, the insolvency of a great railroad corporation and rumored receiverships in prospect for several others are events which have divided attention with the Treasury situation and the silver problem. Happily the gold drain is checked for the moment, leaving an alleged respectable balance of $3,000,000 or upward of free gold for the new administration. The proposed bond issue is still in abeyance, though the advocates of this measure suggest, as a reason for prompt action, that any encroachment on the $100,000,000 reserve might make it no longer possible to sell 3 % bonds at par for gold. With the Government credit impaired, bonds expressly payable in gold might not find a ready market, the metal being held for a premium. An admonition is also found in the fact that although wheat and other commodities are so much depressed, imports are disproportioned to the volume of exports. It is an assuring circumstance that heavy losses among speculative operators have no perceptible effect on legitimate trade. Domestic trade is satisfactory for the season. The east-bound traffic from Chicago is so heavy that the railroads are unable to handle it.

United States bonds were firm at the following quotations:

U. S. 4½s, 1891, extended	99½
U. S. 4s, 1907, registered	113
U. S. 4s, 1907, coupon	112½
U. S. currency 6s	107½

In the merchandise market there are no radical changes. Fluctuations in grain are narrow. Breadstuffs were weak and lower, with dull foreign markets, light export demand and good receipts West.

The possibility of a tight money market inspired caution. While the visible supply of wheat has decreased, the total is at least 111,000,000 bushels, and the holders show signs of fatigue. The foreign markets are supplied in good measure from other sources. Hog products have undergone some reaction and prices are easier. Orders for all sorts of merchandise are curtailed by difficulties in transportation. Rubber is less active. A break in the cotton mills strike in England excites hopes of a better demand for the staple.

The Canadian Pacific Railway is being extended to secure a winter port at Lewisbourg.

Chicago Report.

Scrap.—Old Iron continues very weak, consumers being determined to force prices lower. Dealers quote the following buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	10.00
Cheyenne, Wyo	
All points between Denver and Missouri River	9.35

The London *Ironmonger* publishes the following words of caution to inventors in regard to the proceedings of a questionable French institution calling itself the "Paris Academy of Inventors," which appears to have beguiled a number of British inventors: "We note that quite a number of English inventors have subscribed to the 'Paris Academy of Inventors.' In one case, we know, and probably in others, the academy sent a circular to an inventor as soon as his name was published as having taken out a provisional specification, informing him that he had been elected an honorary member of the Academy for his important invention, and had been awarded the great gold medal (gilded) of the academy. The circular went on to invite him to send £2 to pay for this medal and the diploma accompanying it. In this instance no notice was taken of the circular, but others appear from a set of testimonials accompanying the circular to have been less wary. Had the 'academy' waited till the publication of the complete specifications, its action would have appeared less questionable, but acting as it has done, it is obvious it neither knows nor cares what the invention is to which it awards its diploma, as until the patent is completed its title only is published."

Hard times in Canada are believed to be at the bottom of the agitation for annexation.

CONDITION OF THE

Hardware Trade.

THE BUSINESS of the past month is generally regarded as very satisfactory and as having been larger than last year. There was a heavy trade in some of the staple lines, which still continues, keeping manufacturers busy and suggesting that perhaps there may be a shortage before long. At the same time, the business in general Hardware has been at least up to the average, so that there is little reason for complaint, in view of the trade with which the year has opened. With the advance of the season there is now an increase in orders, and both jobbers and manufacturers are kept fully occupied. In prices there is some improvement on certain lines of goods that lie near the raw material, but, as a rule, the Hardware market is not characterized by special strength. There is a disposition on the part of the trade to buy only in such quantities as their business is sure to demand in the near future, their policy being to purchase frequently and in moderate lots rather than to place liberal orders. There is an evident sluggishness in collections in many parts of the country, which is accounted for in part by the general financial condition and also by the disposition of the farmers to hold their products, while, at the same time, the condition of the roads and the character of the weather have interfered to some extent with the usual course of business.

Advices from Chicago.—Hardware jobbers report a better condition of trade, which has been improved to a considerable extent by the firmer feeling in staple goods. The tone of reports now coming in from traveling salesmen has changed decidedly. Up to the past week they complained of brisk competition on Wire Nails and other staples and expressed very bearish views on the situation. Advices received from headquarters, however, withdrawing former quotations and insisting on the cancellation of offers previously made, immediately brought about a very decided change. Merchants came to the conclusion that the bottom had been reached and orders from that time have been coming in briskly. The Shelf Hardware jobbers and Heavy Hardware jobbers both report their sales larger than up to the corresponding time last year. A still heavier rush is expected as soon as spring opens, which must be during the course of the present month unless all reasonable signs fail. The question will then be how to get goods rather than what they will cost. Collections are not as favorable as they have been. This is imputed partly to the policy of the farmers in continuing to hold on to their stocks of grain, and partly to the efforts of Eastern banks to create an artificial scarcity of money. The situation is not regarded with apprehension, but is expected to clear itself up naturally as the season advances and grain stocks are released from farmers' hands.

Notes on Prices.

Cut Nails.—The adoption of the Wire Nail card by the Eastern manufacturers at their meeting at Philadelphia, 21st ult., ratifying the action of the Western manufacturers at the Pittsburgh meeting, 15th ult., is generally regarded by the trade with approval. The object sought to be accomplished—namely, the doing away with the troublesome system of averages and simplifying business by the use of a common list for both Wire and Cut Nails—is commended very heartily, and hopes are expressed that the project will be successfully carried out. Quotations in the East are on a basis of $1.25 in carload lots at mill, and $1.40, New York, which is slightly higher on usual assortments than the price recently ruling. Manufacturers both East and West are making quotations on the basis of the new card without any reference to average, but specify in some cases that the price named is for "ordinary assortments," one company stating that their future quotations "will be made at a straight base price with the single condition that the quotation is made for ordinary assorted specifications." It is also understood that at the meeting of the Eastern Association last week it was stipulated that no order would be considered assorted unless it averaged as high as 10d Nails, or 50 cents per keg above base.

In adopting the Wire-Nail card for Cut Nails the Eastern manufacturers, as mentioned in our last issue, made some slight modifications so as to adapt it more fully to Cut Nails, and it is understood that these changes will be ratified by the Western manufacturers. The modifications made are shown in the lists given below, which represent the regular Wire-Nail card, and also that adopted by the Cut-Nail manufacturers. It will be observed that the Cut-Nail card differs from the regular Wire-Nail card in the extras named on Fine Finishing, Clinch, Tobacco and Flooring Nails, as it provides for Nails omitted on the regular Wire-Nail card, while it increases the extras on Clinch Nails to 50 cents above the same size of Common Nails, instead of about 20 cents. Other changes are also made. On the leading goods, however, the two cards are identical, and these minor differences will probably be of little practical importance. We give below the regular Wire-Nail card and that adopted by the Cut-Nail manufacturers in parallel columns, so that the precise differences may be perceived at a glance:

Common, Fence, Sheathing, Hook, Brads and Shingle.	Extras. Cut Nails.	Wire Nails.

Advices from Chicago.— Manufacturers report large shipments during the past week, as specifications have been coming in rapidly on old contracts. The new price of $1.42½, Chicago, for factory lots with no average is maintained, but buyers are withholding their purchases as long as possible to see whether the rate is firmly fixed on the basis named. Jobbers report that the rate of $1.50 from stock on the new card is adhered to, and that so far they have met with no trouble in putting the new arrangement in operation.

Wire Nails.—During the past week or two there has been a large business in Wire Nails, some of the leading jobbing houses having placed heavy orders, and many smaller concerns covering their future requirements. The market is characterized by an excellent tone and prices are somewhat higher. At a meeting of the manufacturers held in Cleveland last Friday the price was advanced to $1.50 for round lots at mill. Small lots from store in New York are selling at $1.75 to $1.80.

Advices from Chicago.—Heavy contracts were made during the early part of last week by merchants in the Northwest, who at last became convinced that prices of Wire Nails were on a firm basis and that it would no longer be advisable to defer their necessary purchases of stock. Those who did so were wise, as manufacturers held a meeting later in the week and advanced prices to the equivalent of $1.65, Chicago, for factory shipment. The advance is likely to be sustained now, as manufacturers are loaded with contracts. Stocks are reported light everywhere in the hands of distributors, and the usual spring demand is expected to reach larger proportions than ever. Jobbers have advanced prices to $1.70 on small lots from stock.

Barb Wire.—The Barb Wire market is characterized by an excellent tone, with a large and increasing volume of business. Some of the mills are withdrawing their extreme quotations, and prices are somewhat higher than they have been. For carload lots at mill $2.40 to $2.45 represents the market, but some of the manufacturers are asking higher figures. Small lots of Galvanized Four Point from store in New York are regularly held at $3.10, an abatement of 10 cents per 100 pounds being made in carloads.

We are advised by George H. Munroe, receiver, that he has booked orders and closed out the entire stock of Barb Wire of the Joliet Enterprise Company, there being less than 1000 tons now in the warehouse, which will all be shipped not later than 15th inst. Sixty days ago there were nearly 4000 tons on hand. The Wire has been sold largely to old customers of the Joliet Enterprise Company and at fair prices, the receiver having taken special pains not to demoralize the Barb Wire market while closing out this stock. The plant has not yet been offered for sale.

Advices from Chicago.—The demand is now quite large from manufacturers, and is improving from jobbers. Inquiries are coming forward in constantly increasing volume, and the question will probably be in a couple of weeks to the manufacturers: "Can you ship the Wire?" A very heavy trade is expected from all indications. The high grade Barb Wires sold through exclusive agencies will be advanced, it is stated, at least 10 cents per 100 pounds this week to, say, $2.75 for Galvanized and $2.35 for Painted, in carload lots from factory. An advance on other Wire is regarded by manufacturers as a decided probability within the next week or two. Jobbers are now quoting $2.65 for Galvanized and $2.25 for Painted in small lots from stock.

Wrought Iron Pipe.—The volume of business is fair, but the market is weak and manufacturers are apparently very desirous of securing orders, and to this end are naming concessions on former prices. Quotations now ruling are, we are advised, lower than have prevailed for the past 18 months.

Shot.—The Shot market continues without important change, prices being steady, with only a moderate business. The Philadelphia Shot Tower, Thomas W. Sparks, 121 Walnut street, Philadelphia, in sending out their regular quotations state that an additional discount of 2½ per cent. will be allowed on lots of 2000 pounds and upward.

Cork Screws.— Detroit Cork Screw Company, Detroit, Mich., issue a list of Cork Screws and Cork Extractors manufactured by them, from which it is seen that the line covers a large range both in styles and prices. The list prices are as follows and subject to a discount of 33⅓ per cent.:

	Per doz.
Davis Knife and Cork Screw	$2.00
Davis Cork Screw	6.00
Columbus Power Cork Screw	3.60
No. 1 Cut-Worm Cork Screw	1.50
No. 2 Cut-Worm Cork Screw	1.00
No. 3 Cut-Worm Cork Screw	0.75
No. 3 Greely's Cork Extractor	1.50
No. 4 Greely's Cork Extractor	1.80
No. 6 Greely's Cork Extractor	2.50
No. 7 Greely's Cork Extractor	2.50
No. 8 Greely's Cork Extractor	2.50
Puddefoot Cork Screws	3.00
Cut-Worm Screws for Bar Cork Pullers, per 1000	90.00

Chicago Spring Butts.—Chicago Spring Butt Company, Chicago, Ill., have recently reduced the list prices of their Nos. 41 and 51 Double Spring Butts. The revised list is as follows, which is subject to a discount of 30 per cent.:

	Per pair.
⅜ to 1-inch, Nos. 41 and 51	$7.25
1⅛ to 1¼ inch, " "	8.00
1⅜ to 1½-inch, " "	10.75
1¾ to 2-inch, " "	18.00
2¼ to 2½-inch, " "	27.00
2¾ to 3½-inch, " "	36.00

Motley's Adjustable Sash Holder.—This article, which is manufactured by Peter Motley, 750 South Broad street, Philadelphia, is sold, medium size, in gross.

lots, at $1.50 per dozen; subject to a discount of 40 per cent.

Glass.—The glass market is quiet and uninteresting, with but little doing in either American or imported Window Glass. This is largely due to the severe weather experienced throughout the country, which has almost entirely caused the suspension of building operations. At a meeting of the National Window Glass Company, held at Chicago, last week, a change was made in the discount for Glass in any quantity less than carloads. The revised price for less than carloads is 80 and 10 per cent. discount, instead of 80 and 10 per cent. discount for 100 boxes and over, and 80 and 5 per cent. discount for less than 100 boxes, as formerly. Discounts on other quantities remain unchanged. A freight allowance will, however, be made on carload lots and larger quantities, not to exceed 17½ cents per 100 pounds. Less than carloads will be sold f.o.b. at the shipping point. We are advised that the National Window Glass Company now include 93 per cent. of the Pittsburgh, Western and New York State factories, and 90 per cent. of the Glass jobbers in the country. The New York importers of Window Glass held a meeting on the 27th inst., but came to no decision regarding future prices. While the nominal discount on imported Glass is 75 and 10 per cent., in the absence of business no definite price can be named. Glass is, however, being sold at from 80 to 80 and 5 per cent. discount. The Plate Glass market remains without change, both in regard to prices and demand. We quote as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 80 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Cut Nail Card from the Jobbers' Standpoint.

The following letter from a well-known house in Ohio discusses the question as to the desirability of a revision of the Cut Nail card, referring especially to the inconvenience suffered by wholesale houses who sell Nails to the smaller trade. Our correspondent points out the advantage it would be if the system of averages were abolished. Whether the adoption of the Wire Nail card for Cut Nails will accomplish this remains to be seen:

I read with interest a recent article in your paper on Cut Nail card. If the writer of the article had to sell Nails in a jobbing way to the retail trade I think he would sing another song. Jobbers cannot charge their customers on the same basis they have to buy on. Only last week we received the following order for Cut Nails:

6 kegs 40d.
3 kegs 20d.
4 kegs 60d.

This order was from a coal company who use scarcely any small Nails. The average above base is 5 cents a keg. Now, what would our customer say had we charged him the same rate manufacturers would charge on such an average? He would have returned the invoice for correction, and possibly added some exclamation points. A great many retail dealers are sharp enough to buy their large sizes from jobbers and small ones from manufacturers; in that way they can shape their stock so as to get a high average and low price when they are ready for a carload. There is no good reason why the loss on one-sized Nail should be added to another size. Manufacturers know what it costs to produce each size, and the only correct way is to sell each size on the basis of the cost of same. Why should a man who wants a keg of 50d Nails pay more than they are worth to help some one else buy a keg of 3d Fine for less than they are worth? And if the manufacturers' system is carried out, that is just what the buyer of the 40d will have to do. The jobber cannot fix a price based on exact cost on more than one purchase at a time. He may have a car this week with a high average and low prices, and the next car may cost him, on a different average, from 5 to 10 cents a keg more; but he dare not change his price unless manufacturers have made a change.

The average dealer knows nothing about the present system, and it would take one man's time to explain it to them so they would remember it. If they could take a Nail card and know the base price, they could tell exactly what Nails would cost them; and it makes no difference to them whether a customer buys 3d Fine or 60d, he makes his profit.

We would like to see a card so arranged that manufacturers could return to the old system, and think it would be fully as profitable to them and much more satisfactory to jobbers and retailers.

Trade Notes.

The New York Exhaust & Blow Pipe Company, 26 Mechanic street, Hartford, Conn., publish an illustrated circular relating to Galvanized Steel Exhaust and Blow Piping of their manufacture. A description of the Piping is given and a list of testimonial letters presented.

The Clayton & Lambert Mfg. Company, Ypsilanti, Mich., issue an illustrated circular descriptive of their No 1 Gasoline specialties. They introduce the circular with a brief history of their No. 1 Burner, and then proceed to give illustrations and general descriptions of the several varieties of Fire Pots, Torches, &c., of their No. 3 Fire Pot and No. 4 Brazing Fire.

The Challenge Iceberg Hardwood Refrigerators, manufactured by the Challenge Corn Planter Company, Grand Haven, Mich., are referred to in an announcement elsewhere in this issue. Illustrations are presented and a list of agents given.

Seavey & Co., Tinware manufacturers and dealers, for a number of years located at 93-97 North street, Boston, will remove to the convenient building 120-122 North street, directly opposite their present quarters. The change will be made about May 1.

The Peck, Stow & Wilcox Company, Southington, Conn., and 27 Chambers street, New York, are just issuing what they designate as a Columbian edition of an illustrated catalogue and price-list devoted exclusively to the treatment of a line of goods known to the trade as Tinsmiths' tools and machines. The book is finely printed on plate paper and has 160 pages 7½ x 5½ inches. In addition to the staple goods so long and favorably known to workers in sheet metals in this and foreign countries, we note the incorporation of many new numbers and sizes of articles already well introduced, thus affording a larger variety to select from. This is most marked in the assortment of Forming Machines and Squaring Shears for hand, foot and steam power, while various patterns and styles of Corrugating Machines and Beaders are entirely new.

H. M. Hillson, manufacturer of Tinware and house furnishing goods, at 247-251 North street, Boston, Mass., will, about May 1, remove his offices, show and shipping rooms to the building, 93-97, on the same street, now occupied by Seavey & Co. Mr. Hillson has purchased these premises, and will remodel them to suit his requirements. The former offices and storerooms will be added to his manu-

facturing plant, which will make in all six floors available for factory purposes. The new move will bring Mr. Hillson into the heart of the Tinware district, and prove a convenience to his patrons, who will be welcomed with the old-time cordiality in the new quarters.

WORTHLEY'S BROAD GAUGE IRON STALL WORKS, 53 Elm street, Boston, Mass., issue an illustrated catalogue of their Stable Fittings, which include a variety of articles, such as Mangers, Cesspools, Water Troughs, Racks, Stall Guards, Hinges, Lanterns, &c.

THE MICA INSULATOR COMPANY filed articles of incorporation March 1, 1893, at Elizabeth, N. J., the authorized capital being placed at $100,000, all paid in. The company's plant is located at Schenectady, N. Y., while offices will be maintained at 218 Water street, this city, and also at Elizabeth. The incorporators are: Eugene Munsell of Branchport, N. J.; Lewis W. Kingsley and Franklin Brooks of Elizabeth, N. J.; Charles W. Jefferson and Arthur H. Salisbury Dyer of Schenectady. The company will manufacture Micanite for electrical insulation, a description of which appeared recently in our columns. Through processes controlled by this interest mica waste is now utilized in all forms and shapes for insulating purposes at a much reduced cost, with no diminution in efficiency.

JAMES A. COE & Co., 106 Mulberry street, Newark, N. J., make an announcement this week respecting the American roofing plate known as Staple, which they handle. The advertisement also refers to Black and Galvanized Sheet Iron and Sheet Zinc.

IN *The Metal Worker* of February 25, referring to the New York office recently opened by N. & G. Taylor Company of Philadelphia, there was an error in the number of the street. It should have read 231 Water street, New York.

SUMMERS BROS. COMPANY, at Struthers, Ohio, have been running full time. A number of important changes will be made in these mills during the coming season. A new sheet mill will be built which will be one of the best equipped plants in the valleys.

WE LEARN from the E. W. Bliss Company, Brooklyn, N. Y., that in consequence of increased facilities for the manufacture of their Standard Presses, they are offering their Adjustable Power Presses Nos. 10, 12, 12½, 18 and 19 at reduced prices. They state that these Presses are kept in stock and shipment can be made at once.

HAYDOCK & BISSELL, 12 Murray street and 15 Park place, New York, announce an important auction sale on Tuesday, March 7, when a large assortment of Agate, Blue and White Ware and Stamped Tinned Ware Seconds will be offered by order of the Lalance & Grosjean Mfg. Company. First quality Enameled Sheet Steel Drip Pans and Wrought Steel Kitchen and Pantry Sinks, enameled, galvanized and painted, will also be disposed of. The above goods will be sold in quantities to suit the jobbing and retail trade and without any reserve.

F. G. FERAUD, for many years cashier of the Peck, Stow & Wilcox Company in New York, but since 1887 a resident of California, has recently been elected secretary of the Redlands Electric Light & Power Company, of Redlands, in that State, a town of 4500 population, about 60 miles from Los Angeles. This is in addition to other duties, among which may be mentioned the cashiership of the National Bank there, and an executive position in an irrigation company.

CHARLES F. BROOKER, for 24 years secretary of the Coe Brass Mfg. Company of Torrington, Conn., has been elected president of that company to fill the vacancy caused by the death of Lyman W. Coe.

THE SALEM NAIL COMPANY, O. Nelson, proprietor, 292 Pearl street, New York, issue a card under date February 10, in which they state that, having anticipated the recent advance in the price of Cut Nails and having excellent facilities and a commodious warehouse, they are in a position to fill orders promptly at the lowest market prices. They mention that they always carry a full line of Plain and Galvanized Wire and Cut Nails.

THE BROWN DEVELOPING COMPANY, 97 Chambers street, New York, and 45 Oliver street, Boston, have been carrying on a test of their Crematory Furnace at Boston, consuming the city garbage. During the test the temperature at the head end of the furnace was 2500°, at the rear end 1800°, and at the neck of the stack 1650°. A 45-inch stack was substituted for the 20-inch one in use, which it was expected would carry the temperature from 500° to 800° higher. Of this company J. C. McCarty, of J. C. McCarty & Co., 97 Chambers street, New York, is secretary.

ERIE SPECIALTY MFG. COMPANY, Erie, Pa., were the recipients during 1892 of a largely increased trade, which has necessitated the enlargement of their plant and the addition of new machinery. The company are now running overtime, and the books contain many large orders, the prospect for business during 1893 being very gratifying.

Price-Lists, Circulars, &c.

THE BRONSON SUPPLY COMPANY, New York, sole agents for Puritan Cookers: Illustrations and list prices are given of a variety of styles of Puritan Cookers, also of Five o'Clock Tea Kettles, Coffee Pots, Chafing Dishes, Baking and Vegetable Dishes, Egg Poachers, Cuspidors, Spice Nest, Tea Steepers, Universal Measures, &c.

THE ST. LOUIS REFRIGERATOR & WOODEN GUTTER COMPANY, St. Louis, Mo.: The Centennial Refrigerator. Illustrations are given of Refrigerators, Sideboard Refrigerators, Ice Chests, Grocers' Chests, Barroom and Saloon Chests, Wine Cooler Refrigerators, Portable Refrigerators, Grocers' Butter Boxes, Beer Coolers, &c.

THE LUDLOW-SAYLOR WIRE COMPANY, St. Louis, Mo.: Illustrated catalogue of Crestings, Finials, Stable Fixtures, Tower Ornaments, Weather Vanes, &c. In addition to these goods, the company call attention to all goods of this character, as well as to their general line of manufactured Wire Goods; also Barb and Plain Wire, Metal Work of all kinds, Wire and Iron Fences, Wire Nails, &c. Catalogues and prices will be furnished upon application by the company.

NORTH BROS. MFG. COMPANY, Philadelphia, Pa.: Seasonable Helps for Household Use. Illustrations are given of Gem, Blizzard, American and Crown Ice Cream Freezers; Freezer Clamp, Ice Chipper, Keystone Beater, Gem Cake Pan, Gem Cake and Batter Mixer, Perfection Meat Cutter, Gem Ice Shave, &c.

PARAGON MFG. COMPANY, New Haven and New York; salesroom 112 Chambers street: Illustrated price-list. Cuts show Pipe Vises, Cast-Iron Hammers, Gas Pliers, Can Openers, Speed Indicators, Ice Picks, Brackets, Tack Claws, Coat and Hat Hooks, Tinners' Snips, Scratch Awls, &c.

Beet sugar production in Europe has entirely cut off the demand for Cuban sugar in that direction.

The Duty on Pig Tin.

An extraordinary state of affairs grew out of a mistake made by the representative of the Associated Press at Washington last Saturday. In the rush of the closing hours of business in the Senate the reporter was led to the assumption that that provision of the McKinley bill had been repealed which calls for the imposition of a duty of four cents per pound on pig tin after July 1, 1893. All the leading daily newspapers had accounts of the passage of a repeal act, and accordingly the metal showed a declining tendency at the exchange. Some doubts as to the accuracy of the information arose, and soon a number of telegrams were forwarded to different persons in Washington asking for precise information. The answers were conflicting and in some instances evasive. Thus, one of the New York Senators replied that his impression was that the duty had been abolished. It was only after a day's suspense that the news became definitely known that the bill had failed of passage. One leading broker before the opening of the exchange purchased a considerable block on advance information, but the market declined at the opening, since no authoritative reports were at hand. It is stated that the uncertainty thus created led to sales of part of the metal acquired. Then prices began to advance, and have risen since, with occasional slight declines, the net result being quite a considerable advance. It was reported that all the leading houses are pretty well supplied with the metal, and that the wholesale trade generally looks with gratification upon the outcome, since it seems to afford the first opportunity for some years to make a fair profit on transactions in the metal. London, too, had its period of suspense, when a short interest was developed. The leading speculative clique is reported to have held its ground and to have punished its adversaries by a sharp advance, the price jumping £2 sterling in one day. It may be well questioned whether in the history of the metal trade there has been so curious an instance. It is deeply to be regretted that the act failed, since it has become quite obvious that no sufficiently rapid development can take place during the next few years to justify the expectations held out when the law was passed.

Touch as a Test of Temperature.

It is a common practice with steam and hot-water heating fitters to base a judgment of the working of a heating apparatus upon the temperatures of pipes and radiators determined by sense of touch. When experience has matured judgment the sense of feeling may indicate and locate defects that otherwise could not be discovered in any other way so easily, since it is impracticable to insert thermometers in all parts of a system of pipes and radiators; and even were this to be done the process of reading thermometers is slower than the application of the hand. By practice one may learn to touch a very hot pipe without danger of burning, and by this brief test to estimate its temperature with sufficient accuracy for the purpose of determining whether it is working effectively or not. On the contrary, an estimate of the temperature of a room by the sense of feeling, unchecked by the indications of a thermometer, is likely to be very much at fault. To one person a room may feel comfortably warm, while to another it will seem chilly. In two hours' time the first may be complaining of chilliness, while the second feels warm enough; and either one, if too warm, will generally estimate the temperature as several degrees higher than a thermometer would show it to be, or if they felt cold would make an error precisely opposite. We have, therefore, this peculiarity of the human skin clearly manifested—to wit, that it is more reliable in its sense of temperature changes in solids (the same may be said as to liquids) than it is for the temperature of air; and as air is a mixture of gases it may be generally said of these, as a class, that an approximation to their temperature by the sense of feeling is more unreliable than it is with other substances.

An Explanation.

The human skin varies sensibly in temperature within small intervals of time. In taking the temperature of patients, physicians place the bulb in the mouth or sometimes in the armpits, these latter parts being protected largely from external influences that affect the temperature of the skin. In a room heated by a stove or by steam or hot-water radiators placed directly in the apartment, the skin, all other things being the same, will be warmer than in a room heated to the same temperature by indirect systems. This is an effect of radiation directly upon the skin from the apparatus that supplies the heat. To produce an equal degree of comfort in a room warmed by heated air only a higher temperature will be required. Let a person step from one room to the other, both being at an equal temperature, as shown by a thermometer, and he will nearly always think the room indirectly heated is the colder.

Errors in Guessing Temperature.

But there are other and more effective causes for errors in such estimates—that is to say, causes for temperature changes in the skin itself; for people feel warm or cold, according to the temperature of their skin, often quite independently of the temperature of the air and surrounding objects. A man lying in the hot July sun and shivering with chills feels cold, not because there is less total heat in his body that there was five minutes before the chill began, but because the skin has become colder than is normal. The warm blood has temporarily left the vessels of the skin and has been forced into the interior blood vessels. In a short time this condition will be reversed, and then the sufferer will complain of heat, the temperature of the air all the while remaining the same. It is clear that a man with fever and ague would be a very poor judge of the temperature of heated apartments. Aside from conditions of disease or health, there are always four things that influence the temperature of the skin. These are heat radiation from either an artificial source, as a stove, a direct radiator, burning gas, &c., or from a natural source, as the heat of the sun, the presence of moisture in the air, the temperature of the air, and air currents. Of these, radiation from sources of heat, moisture in the air, and the elevation of the temperature of the air, all tend to increase the temperature of the skin; while air currents, even when the air is as warm as the skin would be were there no currents, are cooling in their effects because they promote evaporation, and evaporation of moisture from the skin always cools it. None of these influences materially affects sensation in placing the hand upon a heated solid. The nerves respond to the touch of hot iron almost as quickly in the patient undergoing a chill as in a well person, and his skin can be burned as readily in the cold as in the hot stage. It is thus seen that while there are a group of causes that tend to render the sense of feeling unreliable as a test for temperatures in air, none of these materially affects the sense of touch as a test for temperatures of solids and liquids.

Ventilation of Public Schools.

In a recent lecture delivered before the Department of Pedagogy of the Brooklyn Institute, Dr. Jerome Walker made some startling assertions relating to the defective ventilation of public schools generally, and of the Brooklyn schools in particular. The lecturer's remarks about the Brooklyn schools attracted immediate and marked attention on the part of the Brooklyn newspapers, because it has been given out, and very generally believed, that the schools of that city are

very much better ventilated than those of New York City, and that they compare favorably as respects ventilation with those of most cities in the United States. Dr. Walker charges the following ailments common among public school pupils to defective ventilation: "Lassitude, headache, nervous fatigue, irritability, glandular enlargement, scrofula, sore eyes and various infectious diseases." He insists, according to printed reports of his lectures, that proper ventilation of a school cannot be effected with less than the admission of 1800 cubic feet of pure air per hour for each pupil. A school of 100 pupils would therefore require 180,000 cubic feet per hour, and estimating five hours per day as the average time which scholars attend in cities, and that during the noon hour ventilation will be maintained at the above rate in order that the air in the room shall be pure upon the reassembling of the pupils for the afternoon session, 1,080.000 cubic feet per day for every hundred pupils will be required, and to heat this air from zero to, say, 65 F. would require 16,707,600 units of heat. Allowing that in a boiler large enough for this amount of heating 9 pounds of water per pound of coal burned will be evaporated per hour to produce the heat for warming the air for this amount of ventilation, about a ton of coal will be needed to be daily burned for each 100 pupils, which, at an average of $5 per ton, would cost 5 cents per day for each pupil. to say nothing of the cost of maintaining some heat in the building during the intervals between daily sessions, and the expense of circulating such a quantity of air, only possible practically by the use of mechanical appliances.

Excessive Ventilation.

Ventilation may be said to be excessive when its cost is unnecessarily increased. If pupils in schools could each get 500 cubic feet of pure air per hour properly admitted it would be more than on an average is supplied even to schools now thought well ventilated by all but extremists; and if the percentage of foul gases cannot be kept down to within the proper limit by the admission of air in this proportion to each pupil, as indicated by the usual tests, the reason should be sought, not in volume of air admitted, but in defective circulation. It might be that even 1800 feet of air for each pupil could be driven through a room containing 100 of them in such manner as to be very inefficient in removing noxious gases and vapors. Effective ventilation not only requires a sufficient air volume, but it also requires that this volume shall be forced through the space to be ventilated in such manner as to expel impure air. It would be well if all who are interested in heating and ventilation would realize (to paraphrase a very old maxim in medicine) that an ounce of expulsion is worth a pound of dilution.

To Evade the Sunday Law.

A decidedly unique suggestion comes from the West anent the World's Fair Sunday-opening question. As our readers know, a very stubborn fight has been made on the Congressional enactment forbidding the local management to open the gates on Sunday. Sabbatarian regulations in Chicago, as well as in some other cities of the West, are decidedly at variance with Eastern customs. The cosmopolitan nature of their people is the cause. Therefore public sentiment approves the use of Sunday for purposes which the more orthodox East most heartily condemns on that day of the week. Residents of other sections of the country do not comprehend the situation, and have consequently been surprised at the vehemence with which the Sunday "openers" have contended for the adoption of their views in the regulation of the World's Fair. They will be still more surprised at the suggestion how to evade this law, to which reference was made in the opening sentence.

Running Factories on Sunday.

The proposition is made, and evidently in all due seriousness, that the factories in and near Chicago should be run on Sunday during the fair, and that the employees should take their day of rest on Monday. The substitution of Monday for Sunday would, it is claimed, give artisans the chance to visit the exposition weekly, for which they have been contending. The Sunday "openers" have steadily asserted that their sole object has been to give working people the opportunity to obtain educational advantages as afforded by the exposition without the loss of time, which is a heavy tax on those who work for daily wages. The proposition to run the factories on Sunday instead of Monday would meet the objection to closing the fair on Sunday, if it were not for the religious question involved. It is true that Sunday is growing less and less a day strictly observed by devotional exercises and more and more a day for relaxation and recuperation. But we are inclined to believe that, even in our most cosmopolitan cities, the time has not yet arrived for such a radical departure from time-honored custom as the substitution of Monday for Sunday would involve. Employers are more conservative than their workmen. A striking lesson can, however, be drawn from this rather startling suggestion, which is that a community is very apt to find a practicable way of defeating a law, if it is not upheld by a strong public sentiment.

Law of Signatures.

One of the simplest things a man does in business is to sign his name, and yet it is a matter around which very much important law is gathered. One law goes back to the time when a signature was of little legal effect. As an incident to legal formality, signature in some form has always been recognized, but it is within a comparatively recent period that men could effectually bind themselves in law by the signing of their names. But now the legal instruments which the law requires to be attested with more ceremonious formalities are few. There are some matters, notably real estate transfers and some others, which the law requires to be witnessed or acknowledged, or both; but for the most part the signature is enough.

In the first place, the signature is merely evidence of the assent of the person whose name is signed to that to which it is affixed. And so it follows that the signature must be genuine, or the person is not charged. And the burden of proving the genuineness of a signature is on the person who claims under it. The one who presents a note for payment must prove the signature to be genuine. Hence it is that one whose name is forged is not put to the proof of the forgery until some proof is made that it is his signature. It takes, however, but a slight degree of proof to throw upon him the burden of showing the forgery. The presumptions of law are all in favor of the genuineness of all records, and where any proof of genuineness is made, it throws upon the other party the burden of showing an alleged falsity.

Assuming, however, the signature to be genuine, it must be a free act of the person to be charged, for it stands only as evidence of assent, and like other evidence, may be disproved. If it has been secured through fraud or duress—that is, under compulsion of threats or personal violence—it is as void as if it were forged, because it is not what it purports to be.

On the other hand, if it actually represents the assent of the person signing, it need not be in his own handwriting. If the name of a person is signed by another in pursuance of instructions to that effect, it is as binding as if signed personally. That simply adds another element to the proof; authority as well as genuineness must be shown. And this principle has been held to apply to those contracts which the statute of frauds requires to be "signed by the party to be charged thereby," because, under the maxim of law that "what one does by another he does himself," the substituted signature is, as a matter of law, his own.

And there is a very important rule applicable to substituted signatures, which all agents, and their principals as well, should bear in mind. The signature must be that of the person to be charged. Let us suppose the execution of a note, with the following signature: "John Smith, Agent for James Jones." There are many who would suppose that to be the note of James Jones, by his agent, John Smith; but this is not so. Such a signature would bind the agent personally, the descriptive matter being stricken off as surplusage. The signature should be, "James Jones, by John Smith, his agent." The signature, "James Smith, President Ninth National Bank," has been held to create a personal liability on the part of James Smith, and not a corporate liability on the part of the Ninth National Bank. The signature should be "Ninth National Bank, by James Smith, President," and this applies to all corporate signatures. Sign the name to be charged, and follow that with explanatory or descriptive designations.

These few points in regard to signatures should be interesting to all business men, because modern business is transacted almost wholly upon informal writings, evidenced only by the signatures of the persons to be charged. The old formalities have gone; they were too ponderous, too slow for this rushing age. And while things are moving so swiftly it is well to know how they are moving.

THE LETTER BOX.

Trouble With a Gas Range.

In *The Metal Worker* of January 28 we published a letter from a correspondent who complained of condensation arising from the use of a gas range. We gave as an explanation that the condensation was due to the lack of ventilation, as the product of the combustion, of course, was water, and unless this was carried off through the flue it would condense on the walls of the room. In *The Metal Worker* of February 18, we published another letter from the same correspondent, stating that the range was connected with the flue by means of a 4-inch pipe. This being the case, we could not understand the cause of the difficulty and referred the matter to our readers. Being considerably puzzled over the subject, we submitted the whole matter to an expert, who has had not a little experience in gas ranges and the use of gas as domestic fuel. His answer to our inquiry is as follows:

"In reply to what you ask about the condensation trouble, I would say that your explanation is correct. If the products of combustion could be carried off there would be nothing to condense. I presume your correspondent has used a canopy with a 4-inch outlet. Now, canopies are a mighty poor arrangement for carrying off steam, smoke or odors. The remedy lies with the makers of gas ranges. Let them make them on the same principle as cook stoves or ranges. I never heard of any trouble from natural gas being piped into a common cook stove or range."

An Appreciative Reader.

From J. T. M., *Cleveland, Ohio.*—I am a constant reader of *The Metal Worker*, and hope to always find its pages as interesting in the future as in the past. I have been silent like the army of subscribers, willing to stand by and listen to others, and then wonder why we do not get more ideas from subscribers who are practical mechanics, and who have a storehouse of knowledge, which has been gained after many years of hard thought and experiment, for mechanics are, as a rule, thoughtful men. Where we say mechanics we say it with its full meaning. The duffers we do not include, as they find their level. Some will say, Who do you class as the mechanic? He is the man who takes a pride and interest in his work, makes it a point to work for his employer's interest, strives to gain a full and competent knowledge of his trade, and has a desire to gain the top round of the ladder.

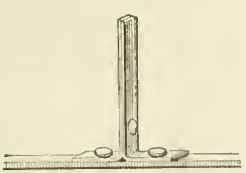
I have a practical talk with my men occasionally on that line, placing myself on a level with them. I advise them how they can become more expert in their work, demand more wages, &c. The great failure in the majority of workmen is they are too ready with this assertion: "We are paid so much money for so much work and do not intend to do any more," so they content themselves with grinding out a day's work, looking toward quitting time, which comes after a long and tedious day. They are afraid they will do too much work for the wages they are getting, hence they work after that style, and the consequence is when slack time comes there is a sifting of the chaff from the wheat. The man who stays is the man who takes an interest and pride in his work and his employer's and has gained a score over his indifferent shop brother, so that he retains his position and is an example for others to follow.

I advise all young men who are training for a trade in the tin shop to subscribe for *The Metal Worker*, as its pages are full of interest and valuable advice. We can all help make *The Metal Worker* more valuable to one another by adding our little mites, for there is no doubt but that all could make some suggestion to simplify ways of doing work and save material from waste.

How often we feel like sending our ideas to the editor on some particular thing, but are so afraid we cannot word our subject right and that we will be criticized by our fellow-craftsmen. But I am sure the editor will overlook our shortcomings and present our ideas to the best advantage for our brother subscribers to ponder over. We are all a family gathering with one object, which is seeking after knowledge, and why not add our little mite, which will be read by hundreds. I can say I have followed the ideas of other writers that have saved me dollars, and had I known them before would have saved me hundreds of dollars. I am a young man in the business and full of ambition to learn from my older brother subscribers their ideas and ways of doing business.

Disposal of Tin Scrap.

From M. N. B., *Sullivan, Ind.*—While working in different shops, I have noticed quite a wastage in scrap tin. When a small article was to be made it was more



Disposal of Tin Scrap.—Method of Making Gutter Hangers.

convenient to cut it from a new sheet than to hunt over the scraps for a piece of suitable size, and the scrap not being properly sorted and cared for, soon became damaged so that its value for anything was very much deteriorated. Consequently, when I took charge of a shop I arranged three large boxes, into which I assorted the tin as follows: Into No. 1 I put all pieces of bright tin large enough to work into tinware. A good many bottoms for articles can thus be taken care of. Into No. 2 all large pieces of terne; and the smaller scraps of all kinds into No. 3. The large pieces of terne make gutter heads, outlets and flashing. The scrap in the third box does for gutter stays and roofing cleats. When a rainy day comes I overhaul this box, first cutting all the strips $1\frac{1}{4}$ x 10 that I can get, next my stays, and lastly roofing cleats. With the strips I make my eave gutter hangers (this may be of interest to some), which I make as follows: First taking two strips, I rivet them together with one rivet about $1\frac{1}{4}$ inches from one end; next I bend the two ends at right angles and form a T, which I rivet on to the center of a gutter stay, as in the annexed illustration. My stays are double folded and folded $\frac{1}{8}$ inch across the ends at right angles, which gives a better hold in soldering into the gutter.

To further stay the gutter and prevent its swinging, I solder some of the strips on the under side and nail them to the cornice. This holds the gutter perfectly rigid and out under the eaves where it belongs, whereas with the old tin strap I frequently meet with gutters that barely catch the drip, and in heavy rains the water entirely overshoots them.

While I do not contend that my hangers are as servicable as the patent ones on the market, I insist that they are much superior to the old strap; and being made from the scrap, are inexpensive. Thus my scrap is disposed of, and without much expense, as the shop boy need not have much experience to do all that is required.

How to Form up Wash Boilers.

From O. J. B., *Troy, Ind*—Can you, or some of the readers of *The Metal Worker*, tell me the easiest and quickest way to form a wash boiler without a former or using a mallet?

Note.—We do not see how this question can be answered to satisfy our correspondent. Any tool or machine which may be made use of to shape the body of a wash boiler, would, we believe, be properly termed a former. The easiest and quickest method to form up a wash boiler body, and which is made use of in most shops, is to form the half-round ends by using the rolling machine for this pupose. Expert mechanics on boilers often form up any number of bodies by this method without using a mallet.

If any of our readers have any special device or machine which could be easily rigged up in a shop for this purpose, we would be pleased to hear from them.

Galvanizing Iron Castings.

From A. M., *Leonardsville, N. Y.*—Please tell me through the columns of *The Metal Worker* how to galvanize malleable iron castings. Can they be coated successfully in such an apparatus as may be arranged in a country workshop? The castings are light, the heaviest not weighing over 1 pound.

Answer.—The following account of galvanizing is given in one of the technical receipt books as applying to sheet iron, iron castings and the like, and presumably is adapted to the needs of our correspondent: The articles are first cleaned by scouring and immersion in a bath of water acidulated with sulphuric acid to remove the oxide. The bath consists of pure zinc, the top being covered with a layer of sal ammoniac. The castings are taken from the water, where they have been placed after being treated by the sulphuric acid, and dipped in the melted zinc. Small castings are taken out in an iron skimmer,

and have to be separated, for as soon as the zinc cools it will solder them together.

Finding the Contents of a Room.

From W. S., *N. Y.*—Please put in plain form the following problem to settle a dispute: How I can find the cubic feet in a room 15 feet long, 14 feet 7 inches wide and 9 feet 1 inch high; also a room 14 feet 6 inches long, 12 feet 9 inches wide and 10 feet 11 inches high.

Answer—To find the contents of the rooms mentioned by our correspondent, it is only necessary to multiply the three dimensions together. It should be borne in mind, however, that the dimensions must be put in feet and fractions, as it will not do to multiply feet by inches. In other words, the first room, to put it in the form of whole numbers and fractions, would be 15 by $14\frac{7}{12}$ by $9\frac{1}{12}$ feet in size. Fifteen multiplied by $14\frac{7}{12}$ is $218\frac{3}{4}$; this number multiplied by $9\frac{1}{12}$ is, when reduced to decimals, 1986.98 cubic feet, or the contents of the first room. Multiplying the dimensions of the second room together in the same way—that is, $14\frac{6}{12}$ by $12\frac{9}{12}$ by $10\frac{11}{12}$—we have 2018.216 cubic feet.

Walls Discolored From Radiators.

From W. J. Y., *Winston, N. C.*—Can you tell me what causes steam pipes and radiators to blacken the walls? In a steam-heated building my attention was called to the fact that just above the radiator and pipes the walls looked as if they had been smoked. The apparatus has been in use seven years, and it was not noticed that it hurt the walls until about two years ago.

Answer.—The discoloration of the walls in this case is due to the current of air set up by the steam pipes or radiators, and which, continually flowing against the walls, deposits little particles of dust and dirt from the atmosphere. This trouble is not confined to a radiator in a room, but is due to any cause that produces a current of air setting in one direction against a wall—that is, where there is any dust in the atmosphere, and there are few places where there is not considerable dust in the atmosphere. The ventilating registers at the top of rooms, especially where there are many lamps burning, will streak the wall for a considerable distance about their orifices. Our correspondent, therefore, need not blame the radiator, for if he had a cold jet from a blower forcing air in the same direction the result would be similar.

Size of Registers for Round Pipes.

From E. S., *New York.*—The following tables can be used to assist one in determining what size of register is required for a certain size of round pipe. As the flow of air is somewhat obstructed by coming in contact with the ornamental face of a register, it is usual to select one having a greater capacity than the pipe with which it is connected. It is also convenient to have the register of such a size that the collar can be attached to the register box and retain its circular form, which renders it more convenient to connect the elbow. By consulting the tables we see that the capacity of a 9-inch round pipe is given as 63 square inches, of a 9 x 12 register as 72 square inches, and of a 9 x 14 register as 84 square inches. Under ordinary circumstances it is probable the 9 x 12 size would be used. The capacity of a 10-inch pipe is 78 square inches, and there are three sizes of registers adapted to this size of pipe, for which the 10 x 14, having a capacity of 93 square inches, is the most used. For an 11-inch pipe, having a capacity of 95 square inches, one can use a 12 x 15 register with a capacity of 120 inches.

Capacity of Round Pipes

Diameter of pipe.	Area in sq. inches.	Diameter of pipe.	Area in sq. inches.	Diameter of pipe.	Area in sq. inches.
Inches.		Inches.		Inches.

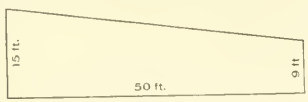
Dividing a Roof.

From C. A. J., *Cobden, Ill.*—As the readers of *The Metal Worker* are anxious to solve problems, I have one which looks very easy, but is very deceiving. Two



Dividing a Roof.

tinners agreed to cover a roof in partnership. The roof was 50 feet long, 15 feet wide at one end and 9 feet wide at the other end. As each one was willing to do his share of the work, they start laying the tin at both ends. Where will they meet and how wide is the roof at the meeting point?

Note.—We have reproduced the diagram showing the shape of the roof, with the dimensions. The problem is to divide the roof into two equal parts, and will, we think, be found somewhat difficult of solution by arithmetic. By another method it is found the roof is 12.37 feet wide at the meeting point. The roofer working from the 9-foot end will have to lay 28.08 feet and the roofer working from the 15-foot end 21.92 feet, if both are to lay an equal number of square feet.

Painting Conductor Pipe.

From F. P. K., *Delaware, Ohio.*—I second the letter of "J. H. W.," Williamsport, Pa., which appeared in *The Metal Worker* of February 18. I think if tinners would pay more attention to what kind of tin to use and let the painters do the painting, it would be much better for them. It is a great nuisance to have everything in the shop daubed with paint. I do very little painting, and if my customers want it done I refer them to some good painter, telling them that he can do a much better job of painting than I can.

Tribulations of the Tinner.

From C. U. B., *Kentucky.*—In reading *The Metal Worker* of January 28, I noticed that our nearest neighbors, the plumbers, were very highly spoken of in regard to their endurance during the cold weather we have been having, soaring way above all other mechanics. Now, although I heartily sympathize with them, and am glad to see that their work is appreciated, I do not think they deserve all the praise. For I think of the sheet-metal worker who goes in to learn his trade, and works for $2 and $3 a week, having to study hard in order to become a good mechanic, and then to have to go out and lay tin, or do a ventilating job on some large building that must be finished within a given time—which is generally very short—with the thermometer ranging from 10 to 35 below zero and the wind blowing so you can hardly stick on the roof. And then think of the poor helper inside the main vent with the warm (?) air that you find about the last of January ventilating his pants legs, with his wages so small that he cannot afford to wear underclothes. Do these men not deserve a little praise, or, what is far better for a poor man, more money? It makes me tired to read advertisements asking for a tinner who can do plumbing, steam fitting, &c.; wages, $10 or $12 a week. But I hear some one say, he is a chump for doing so. Go to his home. Neat and tidy, to be sure. But where is his wife? Sick, sir, with three or four children crying in a corner. It is to keep this little lot a-going that he does it.

City "Lofts."

From A. V. E., *Ottawa, Kan.*—Will you kindly say, through the columns of *The Metal Worker*, what is meant by the many signs I saw on a late visit to New York City: "Loft to Rent," "Second Loft to Rent," &c. On Broadway they attracted my attention particularly. Out here a loft is an open space over a barn, and an advertisement to rent a loft would bring no inquiries.

Answer.—A loft, in city parlance, is a bare unfurnished floor of a building, without fittings of any kind. The first loft is the second floor, or first story above the street, and so on upward.

Trouble with Hydraulic Ram.

From C. S. P., *Duluth, Minn.*—I would advise "C. L." of New Haven, whose trouble with a hydraulic ram has been discussed in *The Metal Worker*, to see that his lead pipe is positively air tight. As to the advice from the correspondent who suggested the use of weight on top of valve, would say that the ram is supposed to, and will, work without it if the difficulty can be located. I claim that the trouble is due to the air getting in between the spring and ram.

Sweating Roof.

From G. W. B., *Newville, Pa.*—Will some reader of *The Metal Worker* please explain to me the cause of a flat roof sweating? One-third is covered with tin, which does not sweat; the remainder is covered with steel, which sweats so badly that the water drips through the ceiling.

"Indian Seam."

From T. A., *Detroit, Mich.*—The following may be of interest to readers of *The Metal Worker* belonging to the tinning fraternity. A manufacturer who, as a young man, was apprenticed to a tinner in Adrian, Mich., relates a story told him by his employer, as to the origin of the term "Indian seam." It appears that the Indians, who at one time, many years since, were quite numerous in that section, would come occasionally to the shop to buy some article of tinware. Unless,

however, the article gave evidence of a burn or scorch mark of the soldering iron, they declined to purchase it, contending that it would not hold water. To satisfy them, it became a practice with the tinner to send the article wanted to the shop and give it the desired scorch, or "Indian seam"—a term then used, which may still be familiar to some of the elders in the trade.

Washington News.

WASHINGTON, D. C., March 7, 1893.

In the haste and confusion of the expiring hours of the Fifty-second Congress conflicting accounts have been published concerning action on the bill to repeal that portion of paragraph 209, tariff of 1890, known as the McKinley bill, which provides that after July 1, 1893, a duty of 4 cents a pound shall be imposed upon block tin.

It was announced that the repeal had passed and this information had reached the Treasury Department of customs division as a current rumor. The Department, however, telephoned to-day to the clerk of the Senate Committee on Finance inquiring as to the status of this subject, and received the reply that the bill of repeal did not pass, therefore the duty on block tin after July 1, 1893, will be 4 cents a pound.

Representative Stone of Warren, Pa., having succeeded in passing in the House his bill for establishing a standard gauge for sheet and plate iron and steel was also successful in getting it through the Senate by giving his personal attention to its progress in that body. The bill also received the approval of the President and, therefore, is now a law.

The text of the bill as passed is as follows from the *Congressional Record:*

Be it enacted, etc., That for the purpose of securing uniformity, the following is established as the only standard gauge for sheet and plate iron and steel in the United States of America, namely (then follows the table of gauges printed in *The Metal Worker* February 11).

And on and after July 1, 1893, the same and no other shall be used in determining duties and taxes levied by the United States of America on sheet and plate iron and steel. But this act shall not be construed to increase duties upon any articles which may be imported.

SEC. 2. That the Secretary of the Treasury is authorized and required to prepare suitable standards in accordance herewith.

SEC. 3. That in the practical use and application of the standard gauge hereby established a variation of 2½ per cent. either way may be allowed.

Therefore in the future all sheet and plate iron and steel must comform to these statutary requirements.

The Western papers report a peculiar migration in progress. Farmers are removing from various localities in States east of the Mississippi River to Southwestern Minnesota, Northwestern Iowa and to Nebraska. The cause of their removal is stated to be the high value of the land which they have tilled for years and the very low price at which they can obtain good farms further West. The enhancement in value is a temptation to those who own their farms to realize, while in other cases landlords are demanding increased rentals this year to correspond with the improvement in value, thus almost forcing their tenants to look elsewhere. Only a few years since cash rents were $1.50 to $3 per acre, but are now $3 to $6. The movement promises to reach large proportions, in some localities having already assumed the appearance of an exodus.

How a Plumber Got Religion.

Our shop enjoys the acquaintance and friendship of several clergymen of different denominations. Among them is a disciple of John Wesley, who stands 6 feet 4 and tips the beam at two-forty. He is not a city preacher, but a true circuit rider. Having spent over a full score of years among the mountains of Virginia, West Virginia and Tennessee, he has acquired a store of personal adventures that would make a rare volume if written and possibly rival those of the justly celebrated Peter Cartwright. If there is anything that he enjoys better than old-fashioned religion, we think it is relating a laughable story.

The following bit of personal experience related by him a few days ago, which has never been published, is too good to lose:

A few years ago while conducting a revival meeting in a small Virginia town located among the Alleghany Mountains, so Brother Vincent says, I met the mayor of the town in a store one day soon after dinner. In the town there was a man named Paul, who ran a tin and plumbing shop, and who was accused by some to be a dealer in "moonshine" on the sly. He was about 45 summers old, considerably bow-legged, not a little pigeon-toed, and had a long Roman nose, a trifle curled to the left. His hair, a sort of dirty brick dust red, stood erect like bristles in a brush; his beard scattering and stained with tobacco juice. Apparently unable to close his lips, his irregular, tobacco stained teeth made him, altogether, about as hideous looking as possible. The one redeeming thing about him was his clothes, which were really quite above the average of the town.

The town authorities had had some difficulty with Mr. Paul about filling up a mud hole in the street in front of his place of business.

He came into the store while the mayor and I were talking and reopened the matter of the grievance referred to. The mayor cut him off pretty short and the tinner-plumber at this proposed to whip the mayor, and started in to do it then and there. I interfered and put a stop to hostilities and made him leave the store. He went away hopping mad, threatening to clean out the town, preachers included. I really feared he would seek an opportunity to chastise me at some unexpected moment and I walked very briskly to church that night, and felt not a little relieved when I reached there without having encountered him.

Upon going into the pulpit and looking over my congregation I was amazed to see him seated in the "Amen" corner looking as solemn as death itself. I felt that he was there for no good purpose, and my sermon was rather briefer than usual, after which I invited penitent persons forward to the "mourner's" seat. To my great surprise Mr. P. was the very first to go forward and kneel. He beckoned me and I went to him. I looked him over very carefully, wondering what was coming next. He looked like a mourner, he acted like a mourner, he prayed like a mourner, he wept like a mourner, but he didn't smell like a mourner. I said to him: "Well, Paul, I am glad to see you here." "Yes," he said, "tell Brother Jackson to come here." I called Brother J., who came at once. Our mourner looked us both straight in the face, as the tears coursed freely down his cheeks, and said: "Brother Vincent, I want you and Brother Jackson to pray for me."

"All right," I responded, "Paul, we will both pray for you." I now began to feel that a great burden was about to be lifted off my mind. Brother Jackson offered a short prayer, in which mourning Paul was specially held up for Divine clemency. Directly the prayer ended Paul, addressing us, said: "Brother Vincent, me or Old White Vinegar (meaning the mayor), the darned old scoundrel, has to die between now and sundown to-morrow. It may be me. If it is I want to go in peace and desire you and Brother Jackson to see my body decently buried; and let me tell you now I don't want any very costly monument put to my grave, but just a plain marble slab with 'Thomas W. Paul, Sanitary Plumber,' on it."

I said: "Paul, if you are through you can rise and take a seat."

"What," he said, "am I through already? Why, darn it, I thought it would take me till the meeting closed and may be another night to get through." He then invited Brother Jackson and myself to come around to his store the next morning and he would "set 'em-up," and, leaning back in his seat, in full view and facing the congregation, commenced singing, "Now I'm glad I've got religion." I did not want him to get too much at one meeting, so I closed the services at once. SWIPED JOINT.

Treasury Decisions.

Drawback on Tin Shingles.

TREASURY DEPARTMENT, January 18, 1893.

SIR: On the exportation of tin shingles manufactured by the Cortright Metal Roofing Company of Philadelphia, Pa., from imported tin plate and paint of domestic production, a drawback will be allowed equal in amount to the duty paid on the tin plate used in the manufacture, less the legal deduction of 1 per cent.

The quantity of the imported material so used shall be determined by allowing 96½ pounds of tin plate for every 100 pounds of the exported shingles. Respectfully yours,

O. L. SPAULDING, Ass't Sec'y.
COLLECTOR OF CUSTOMS, Philadelphia, Pa.

Mottled Enameled Ware.

Before the United States General Appraisers at New York, December 23, 1892. In the matter of the protests, 32,353*a*, &c., of Hermann Aich, against the decision of the Collector of Customs at New York as to the rate and amount of duties chargeable on certain mottled enameled ware, imported per vessels and at dates named in schedule annexed. Opinion by Wilkinson, General Appraiser.

The goods are articles of sheet steel enameled. They were returned by the appraiser as enameled in more than one color, and assessed for duty at 50 per cent., under Paragraph 172, N. T., and are claimed to be dutiable at 45 per cent., under Paragraph 171, N. T. The enamel is of a stone or slate color with a mottled or marbleized appearance. The enamel is laid on in one color and the mottled appearance is caused by the action of acids and heat.

We find that merchandise is not enameled or glazed in more than one color, and sustain the claim that it is dutiable at 45 per cent., under Paragraph 171, N. T.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until 2 p.m., March 22, 1893, for all the labor and materials required for a bathhouse, boiler house, &c., at Camp Low, Sandy Hook, N. J.

Sincere regret is caused by the announcement of the financial embarrassment of the New York & Brazil Steamship Company. The opposition of tramp steamers, and losses from the interruption of business when the cholera was virulent in Santos appears to have been at the source of the difficulty. Even the device of chartering foreign-built steamers, which was finally resorted to, was unavailing to avert the impending trouble.

WORLD'S FAIR NOTES.

Description of Machinery Hall.

In exterior design, says the Chicago *Herald*, Machinery Hall is more than merely grand and imposing. It approaches the gorgeous in architecture, and the general effect of the towers and exterior ornamentation is magnificent. The main building is 850 feet long and 350 feet broad. The interior looks like three large railroad train houses side by side, each spanned by arched iron trusses 125 feet long and 50 feet on centers. Outside of the main hall there is an immense annex, opening directly into the main building. In each of the four corners of the main building is a domed pavilion with a grand staircase. The main entrances are on the north and east sides, with many other entrances along the sides and ends of the main hall and annex. The power plant is on the south of the main building, in a one-story structure which runs the whole length of the building. The ornamental work of the exterior shows the purpose of the building, the statues and portraits representing mechanical forces or great inventors.

Exhibits are being daily installed in Machinery Hall. Three avenues or aisles run the entire length of the main building and annexes, the center one 25 feet wide and the sides each 15 feet wide. Tracks of auxiliary railroads are connected with these aisles and heavy machinery is being taken to its allotted space by means of immense traveling cranes. With a knowledge of every detail of the machinery exhibit, Chief L. W. Robinson is rapidly bringing order out of a chaos of incomplete details. Major Robinson brings to his task not only the discipline of a Government naval officer, but the valuable experience gained as assistant chief of the machinery department of the Centennial Exposition.

The Centennial Exposition created an epoch in machinery exhibits at international fairs. Compared with the Centenial Exposition the machinery exhibit of the coming World's Fair will be full of surprises. While the area for exhibits of machinery has been increased—it was about 14 acres at the Centennial and is about 16 acres at the present time—the amount of available space for domestic exhibits is somewhat less. At the centennial there were 337,000 square feet devoted to American exhibits. At the World's Fair this year the space given to American exhibitors is only about 220,000 square feet.

But while domestic exhibits have been curtailed in space, the World's Fair management has been generous to foreign exhibitors. At Philadelphia the various foreign governments occupied, all told, about 83,000 square feet of space. At Jackson Park they will have a gross space of about 175,000 square feet.

Other comparisons with 1876 are still more striking. At the Centennial Machinery Hall the main power plant was a Corliss engine, 50 x 50 feet. At Jackson Park there will be an electric power plant of 20,000 horse power, covering an area of 112,000 square feet. At the Centennial there were a number of annexes outside of the regular machinery exhibit which contained many exhibits of machinery in operation. At Jackson Park the entire machinery exhibit is massed together, and the limited space has made it a more select exhibit than that of any previous fair. Between three and four hundred applicants for space were turned away, although their exhibits would have been more than up to the 1876 standard.

While the area for mechanical exhibits at the World's Fair is limited, the general display, taking all the groups, will show not only an advanced character of machinery, but finer workmanship in details. The number of firms making the same kind of machinery has vastly increased since 1876, and the competition is greater. In 1876 there was only one firm besides Corliss, in America, manufacturing those great engines that were then a marvel. To-day there are nearly 60 firms making them. In 1876 there were only four or five firms making steam pumps, including Worthington, Knowles, Blake and others, and these were mostly east of the Alleghenies. To-day there are hundreds of firms making steam pumps in almost every State and Territory. Chief Robinson had applications from 74 pump builders for space, of which 43 assignments have been made. The comparison of progress is true as to wood-working and machine tools and printing presses. The average space for individual exhibits at the Centennial was 244 square feet. At the World's Fair the assignments of space are less in number, but the space to each exhibitor is greater, nearly an average of 500 square feet. All the leading machines that are entered at the World's Fair are much larger than those made in 1876, and their variety is greater. To make a comparative exhibit between them a much larger space is required. The largest exhibits at Philadelphia occupied from 1200 to 1600 square feet. At the World's Fair Machinery Hall the largest exhibits will take from 2000 to 3000 square feet.

The general plan of the World's Fair machinery exhibit is simple. The whole exhibit will be on the floor of the main building and annexes. The only gallery space will be given up to restaurants, offices and lavatories. Foreign governments have the choicest location on the main floor. The foreign exhibits begin with those of Great Britain and Canada at the east end of the building and extend west nearly its full length.

The details of the foreign exhibits are in some cases yet incomplete, but the various commissioners promise that everything will be ready by May 1. In the German exhibit the Siemens & Halske Company of Berlin will construct a 1000 horse power engine and electric dynamo, which will furnish additional light for the Machinery Building. The countries from which the most prominent foreign exhibits will come are Canada, Belgium, Great Britain, Mexico, Russia, France, Spain, New South Wales, Italy, Sweden, Austria and Brazil.

The domestic exhibits will be from firms or individuals, there being no groupings by States in this department. The domestic exhibits will be located in the annex and in a portion of the west end of the main building. They will be grouped, as far as possible, in classes, so that a visitor in one part of the building may see in a single department the principal devices in which he is interested. Thus the machine tools, the machinery for fabrics and clothing, the wood-working machines, the printing and typesetting machines and all the other special classes of machinery will be located by themselves.

Of the unique exhibits in Machinery Hall it would take a volume to tell the story. There will be a superb display of machines for the manufacture of paper boxes and kindred exhibits. In the manufacture of textile fabrics the cotton, woolen and silk looms will be of wondrous variety and nicety of detail. The leading exhibitors in this department are the Knowles Loom Works, the Lowell Machine Shops and the Crompton Loom Works. These concerns will show the actual process of making cotton and woolen goods. Silk looms in full operation will be shown by the Atwood Machine Company, Schaum & Ullinger and others, the machines being operated by the Phœnix Mfg. Company of Philadelphia. There will be a fine display of Jacquard looms, which will weave intricate designs of the World's Fair buildings and portraits of prominent men on silk.

There will be a vast product from the hundreds of machines in daily operation in Machinery Hall. Quite a number of concessions for the sale of the more unique products have been given. Those firms that have not obtained concessions will remove their product from Machinery Hall at the close of each day during the exposition.

There will be an interesting exhibit of sewing machines by the Singer Mfg. company, the Standard, American and other works. There will also be shown some special machines of this character, such as a carpet-sewing machine, where the operator rides a velocipede for 100 feet and guides an electric motor, which sews the carpet together as he moves along. There are also machines for sewing wood and leather with wire thread, some of the product being fine enough for a kid glove. Devices of this kind will be shown by J. H. Sternbergh & Co. of Reading, Pa. Several exhibitors will show the latest varieties of knitting machines and cloth cutting machines.

In the northwest corner of the building will be a large display of flour machines from the works of E. P. Allis & Co., Milwaukee; Barnhart & Leese, Moline, Ill., and Nordyke & Marmon, Indianapolis. Flour-mill machinery will be shown in full operation. The display of wood-working machinery will include exhibits by J. A. Fay & Egan Company, S. A. Woods Machine Company, Greenlee Bros. and others, and will be the largest display of turning and planing machinery ever shown. There will be carving and molding machines. One machine will carve out from wood intricate designs and statuettes in groups. In ancient times this kind of work was laboriously performed by hand, and months were spent on a single group. A machine exhibited by C. L. Goehring of Allegheny City will turn out four or five groups of wood statuary in the space of a few minutes. There will be a great variety of machines for geometrical moldings, which are now adopted in the manufacture of furniture and house decoration. These machines have only been on the market for two or three years, and some have recently been sold in Europe for $25,000 each. Large exhibits of machine tools will be made by the Pond Machine Tool Works, William Sellers & Co., Niles Tool Works, and many others.

There will be shown a machine for measuring out and weighing coffee. This machine takes coffee from the hopper and fills 1-pound paper bags, seals them, and does this at the rate of several tons of coffee per day. This exhibit is from Arbuckle of New York City. There is another machine that manufactures tags and labels. It takes the paper from the roll, cuts the tags, prints the labels, punches the eyelets and then inserts the wire for fastening. Another machine makes different sizes of nails from wire. In 1876 the wire nail industry had not begun in this country. There were four or five crude machines shown at the Centennial by French exhibitors. These were purchased by Americans, and since 1876 the manufacture of wire nails has become general in the United States.

Among the exhibits will be machines for expanding metal for use in railings and galleries. A bar of steel goes in at one end and comes out a broad network at the other. This material is largely used as lath in the construction of modern buildings. There will be machines for making hooks and eyes, steel fence posts, sections of telegraph poles and chains. There will be an exhibit of machines for polishing lenses, so that persons who wear

eye-glasses may have lenses polished and mounted while they wait. The C. W. B. Sheridan company will make a fine display of wood-embossing machines that will make wooden medals, with impressions of World's Fair buildings, for souvenir purposes.

At the junction of the main hall and annex will be a tank of water 150 x 50 feet. Grouped around this tank will be the pump exhibit. Scores of modern pumps will take the water from the tank and throw it back again. The De La Vergne Refrigerator Company will build an ice grotto over the tank as an ornamental feature, this being one of the most spectacular features of the whole exhibit.

Another popular exhibit will be the large traveling cranes. These are three in number, operated by electric motors and covering a space of 75 feet over each main aisle. Until the opening of the fair they will be used for installing the heavy machinery exhibit. After May 1 platforms will be built on them and they will be used for carrying passengers. A balcony across the west end of the building will be the landing place. This balcony will also be reached by two elevators, which form a portion of the exhibit by the Crane Elevator Company of Chicago.

Some exhibitors will combine to make a collective exhibit. One instance will be on the south side of the annex, where a large paper mill will be in full operation. About 20 individual exhibitors will be included. Wood pulp will be put through all the processes of a complete paper mill. This exhibit is managed by the Paper Trade Club of Chicago, under the personal direction of Chief Robinson.

Another collective exhibit will be the great display of printing presses that will turn out the morning and evening papers for sale on the World's Fair grounds. There may also be an arrangement among the printing-press exhibitors and bookbinders that will allow the official catalogue to be printed in Machinery Hall. Hoe, Scott, Potter, Goss and all the other great press makers will be represented. There will also be a large exhibit of lithograph printing machinery, job printing machinery, bookbinding machines and linotypes.

The great power plant in the South annex will be a stupendous exhibition of mechanical energy. There will be about 43 steam engines, with a total of from 18,000 to 20,000 horse power. These will operate 127 dynamos, which in turn will produce electric light and power for all the other World's Fair buildings. For the power in Machinery Hall alone there will be 10 or 12 engines, representing a total of about 3000 horse-power. One engine alone in this gigantic power plant is nearly a third larger than the famous Corliss engine of 1876. The largest engine in the World's Fair power plant is built by E. P. Allis & Co. of Milwaukee, and is of 2000 horse-power, as against the 1400 horse-power of the Corliss. One thousand horse-power engines in the World's Fair plant are numerous, one being furnished by Fraser & Chalmers of Chicago.

The dynamos in the power plant, including Edison and all the leading makers, are classed in the electricity exhibit. The boilers are a part of the machinery exhibit, all the leading American makers being represented. There will be about 18 or 20 feed pumps in connection with the boilers, and these, with the large circulating pumps, are also classed as exhibits.

Expense of Fair Exhibits.

"It will cost as much to make the exhibits in the World's Fair buildings as the buildings themselves cost," Director-General Davis said last week in talking of the preparations for the opening May 1.

The rivalry of competitive firms in their exhibits is sharp all over the country, and even extends to foreign countries, where they are to meet on common ground. So keen is this feeling in the wine exhibits of France and Germany at the Horticultural Building that only the barest details are divulged, even to the fair officials. Everything is being held until the last day before work must commence Each is afraid the other will get an inkling of what the exhibit is to be, and either imitate or improve on the original plan.

But it is among the big Chicago firms that the rivalry is the sharpest of all. Plans prepared by the architects are kept well secured in the vaults until time compels that they go into the hands of the builder. The same secresy is observed by the builder.

When it is considered that exhibits costing from $20,000 to $30,000 will be numerous, particularly in the great Manufactures Building, all this precaution is not surprising.

"I would give a good deal to see the plans of the other firms in the trade," one prominent exhibitor said last week. "It would be a big help to us in knowing what to do in particular lines. There are three or four fellows I would outdo if it took my last dollar for advertising the next year."

While the fear of imitation is strong, it is not so generally pronounced as the idea that competitors will endeavor to see all bets and go one better in the game. The men who have charge of the exhibits for the big firms are lying awake nights just now to think of new effects and new combinations for their pagodas and material. A good idea is highly prized and no time is lost in getting it materialized. But these good ideas are guarded religiously.

The total expenditures of Chicago people in their private exhibits are estimated by those well situated to know at about $2,000,000. Director-General Davis' figure that the private exhibits in the main buildings will equal the cost of the buildings is not believed by the chiefs to be excessive.

Every design for booths, pagodas, and pavilions must be sent to the fair officials and passed upon before active building begins. The purpose of this rule is to secure congruity in the grouping. Were every exhibiter left to follow his own aim the individual display might be unexceptionable, but strange and wondrous combinations would be made. Some of them would be quite ludicrous.

This same rule was followed with the buildings throughout the grounds. Every design had to run the gauntlet of criticism in the office of Director of Works Burnham. Few passed without material changes. The number of domes which met their fate at the hands of these critics is said to have been astonishing. Had no such paternal scrutiny been exercised, the collection of domes in Jackson Park and along Midway Plaisance would have been unparalleled in the world's history. It would have been also the laughing stock of architects, regardless of nationality or creed.

The perspective view of the fair has never been lost sight of. The buildings were looked upon as component parts of the whole. The picture of Jackson Park was to be without the blemish of incongruity. And it is.

The interiors of the great buildings are now being treated as a whole. Wide diversity is allowed in the structures to be there erected, but every exhibit is regarded as an integral factor of the whole scene. Some complaints have arisen from the exhibitors, but they are neither numerous nor serious. The reasons for changes are made so plain that a ready acquiescence most generally follows.

Just now exhibitors are being hurried up to send in their designs in order that they can be passed upon at once and returned. While work on many of the pagodas is already under way it will be the middle of March before construction will be commenced generally. April will be the busiest month for this kind of work. With most of it everything possible is prepared at the factories in order to minimize the work at the parks. A fortnight will cause a transformation scene in the big buildings, when the structures begin to fly together. The bad weather has not retarded the interior construction alarmingly thus far, and there are no fears about it not being completed in time.

First Broad-Gauge Locomotive.

The "Lord of the Isles" came to Jackson Park last week. Unlike the "Pioneer," that veteran of the Chicago & Galena Railroad that ran into the park the day before under her own steam, the "Lord of the Isles" came on a flat car, in boxes bound with strong iron hoops. The old locomotive is sent by the Great Western Railway of England. It was the first broad gauge locomotive built in England. She ran out of the shops in 1851, and was one of the star attractions of the World's Fair at London in 1851. The Great Western Railway will make an extensive show at the fair. Seven carloads of exhibits came in one day from that road.

A Novel Feat in Engineering.

An unusual feat in engineering was tried at "The MacKaye Spectatorium" one afternoon last week which served to attract the attention of all the mechanical engineers and builders at Jackson Park. The attempt was made to lift into position, from the ground to a hight of 160 feet, an immense steel roof truss which weighed entire about 30 tons. Usually such a truss is placed in position a piece at a time and then riveted together, but this was impossible owing to the peculiar construction of the Spectatorium, and the truss was riveted together on the ground and lifted to its altitude by an immense two-arm derrick. Despite the predictions of failure which were made by the engineers and others the attempt was a success, and all the other trusses, about 150 in number, will be placed in position by this same derrick. The truss thrown into position first is the lightest one that will be used, the heaviest of the series weighing fully 20 tons more than this one.

The Wellington Catering Company, who control the restaurant privileges at the fair grounds, have just closed a contract with the Rogers & Hamilton Company for the entire silver-plate service required. This is probably the largest order ever given for knives, forks, spoons, &c., calling for 100,000 knives and forks, 200,000 spoons, and everything else in proportion.

The German Commission has received 116 cases of exhibits for the German chemical section. The entire lot weighs 50 tons and is valued at $13,000. The Post Office Department of Germany has forwarded 25 packages for the post office exhibit.

A tunnel is being bored through solid rock under the East River at Seventy-first street, as supposed for the admission of gas pipes connected with Long Island City. On Saturday a foreman in charge, who had just passed through the air lock, suddenly died from the effects of atmospheric compression. The pressure was 40 pounds to the square inch.

The Marine Engineers' Association of America is endeavoring to prevent the licensing of British subjects as engineers of the newly Americanized fast steamships "New York" and "Paris."

House Warming.—V.

CONDUCTIVITY OF MATERIALS.

It will also be necessary to know the conductivity of different materials—that is, their capacity for transmitting heat—specifically termed "Thermal Conductivity." In Table XII., arranged by Box from results of experiments by Péclet, we have the thermal conductivity of different materials. The quantities given in right-hand column represent the number of heat units transmitted per hour for each square foot of surface—the thickness of material being 1 inch and the temperatures on the two sides differing by 1°. Though there are some of the materials named which will not be necessary in our calculations, the table is given entire, as enabling us to see the full range of comparison, from highest to lowest:

Table XII.—Heat Conductivity.

Material.	Heat Units.
Copper	515.000
Iron	233.000
Zinc	225.000
Lead	113.000
Marble—Gray, fine grained	28.000
Marble—White, coarse grained	22.400
Stone—Calcareous, fine grained	16.700
Stone—Calcareous, ordinary	13.680
Glass	6.600
Baked clay—Brickwork	4.830
Plaster, ordinary	3.860
Oak — transmission perpendicular to fibers	1.700
Walnut—transmission perpendicular to fibers	0.830
Fir — transmission perpendicular to fibers	0.748
Fir—transmission parallel with fibers	1.370
Walnut — transmission parallel with fibers	1.400
Gutta percha	1.380
India rubber	1.370
Brick dust, sifted	1.330
Coke, pulverized	1.290
Cork	1.150
Chalk, powdered	0.869
Charcoal of wool, powdered	0.636
Straw, chopped	0.563
Coal (Bituminous), small, sifted	0.547
Wood ashes	0.531
Mahogany dust	0.523
Hemp canvas, new	0.418
Calico, new	0.402
White writing paper	0.346
Cotton wool and sheeps' wool—any density	0.323
Eider down	0.314
Blotting paper—Gray	0.274

To use the quantities or conductive values here given we must know the several conditions required, as follows: Total surface (one side only), in square feet; thickness of material, in inches; difference in temperature of the two sides of the material, in degrees F., and duration of time, in hours. For instance, we require to know the total quantity of heat lost in ten hours from a room by conductivity or transmission through one of the walls or partitions, made, say, of glass $\frac{1}{10}$ inch thick, the wall being 12 feet long x 10 feet high, the temperature in room being maintained at 70° and the outside surface being at 40°. We first look in the table for the conductivity of glass, which we find to be 6.6 heat units. This being for 1 inch thick, and our partition but $\frac{1}{10}$ inch, we must multiply the 6.6 heat units by 10, or divide by $\frac{1}{10}$ = 66 units per square foot per hour for 1°. As we have 12 feet × 10 feet = 120 square feet of surface, 66 × 120 = 7920 units per hour for 1°, and for 10 hours, 7920 units × 10 = 79,200 for 1°. The difference between inside temperature, 70°, and that outside, 40°, = 30°; then, 79,200 units × 30° = 2,376,000 units of heat lost from partition under above conditions. Supposing the partition to have been made of 18 inches of ordinary stone, all other conditions remaining the same. By the table we find 13.68 to be the conductivity. Then $\frac{13.68}{18}$ × 120 × 10 × 30 = 27,360 units per hour.

From this we may deduce the formula: Loss of heat = $\frac{\text{conductivity, as per Table XII.}}{\text{thickness of wall, in inches,}}$ × surface of wall in square feet × time in hours × difference in temperatures of the two sides of wall. Or, $(C \div T) \times S \times H \times D$ = loss, wherein C = conductivity, T = thickness of wall, S = surface of wall, H = time and D = difference in temperature.

LOSS BY RADIATION.

Another source of loss of heat is that of radiation. Although somewhat difficult to realize, it may be defined as the direct passage of heat from a body to one of a lower temperature, at a distance from it more or less remote, and regardless of the temperature of the intervening atmosphere. While in such a connection it is very difficult to eliminate from the question the element of distance as interposing between cause and effect, it nevertheless is accepted as a fact that radiation of heat is entirely irrespective of the distance between the source of heat and the body by which it is received. In other words, that the radiant body will give off a certain amount of its total heat to the nearest absorbent body or bodies, no matter how remote the latter may be. This peculiar phenomenon is one with which (or its effect, rather) all are familiar, although from that very fact it fails to excite notice—the more so, as its effect might easily be attributed to other causes.

For instance, if we stand in a cold room—say at a temperature of 30°—within a short distance of a hot stove in which a fire has been freshly kindled, the sensation of heat is very perceptible, notwithstanding that the air in the room is uncomfortably cold. It would be very natural to attribute the feeling of warmth entirely to the increased temperature of the air in contact with and surrounding the stove, which had not yet had time to become diffused and thereby equalize the temperature throughout the room. This is not the fact, however, as we may easily demonstrate by holding the hand extended (with the palm parallel with the heated surface of stove) and carefully noting the effect. The palm will feel the heat very sensibly, while the back of the hand is unquestionably cold, although it is practically at the same distance from the stove, and consequently subjected to the same atmospheric temperature as the palm. If, now, we reverse the position, and turn the back of the hand toward the stove, and the thickness of the hand, say 1 inch, nearer, it will instantly become sensible of the heat, while the palm will feel the contact of the colder air, although it is at exactly the same distance from the source of heat as when it was turned toward the stove and felt warm. This shows very conclusively that the sensation of warmth cannot be due to an increase in temperature of the air immediately surrounding the stove, as in that case both sides of the hand must feel equally warm.

To illustrate this point still further, let us suppose a large bonfire in the open air, and a strong breeze blowing. Standing moderately close, on the windward side of the fire, we feel the heat to be intense, although the cold wind is constantly carrying away from the fire (and the observer) every particle of air which has become heated by contact with it, and therefore there can be no increase of atmospheric temperature on that side, while on the opposite or leeward side it may be felt very sensibly. It would seem clear, therefore, that there must be some direct means of transmission of the heat, irrespective of any conducting medium; and this is what is understood by the term radiant heat. It is stated by some eminent authorities that the heat rays pass directly from a hotter to a colder body, for a moderate distance, without appreciable loss or raising the temperature of the air through which they pass. This, however, can hardly be true, as the closer the recipient or absorbent body may be to the fire or other radiant body, the higher will be the increase of temperature by its absorption of the heat rays. And, *per contra*, if the distance between the two bodies be comparatively great, the absorbent receives a correspondingly less increase in temperature.

It might be argued that the closer the absorbent to the radiant the greater would be the number of heat rays of a definite power absorbed by the former, and that the number would be proportionate to the distance, for the reason that at the longer distance they would diverge, and thereby cover a larger amount of surface. This, of course, would indicate that a given number of rays would be radiated from the hotter body, and all of them be absorbed by the recipient upon an amount of surface proportionate to the distance. In other words, that if, for instance, at 1 foot distance a square foot of surface would have imparted to it by the heat rays 1000 units of heat, the same number would be absorbed by, say, 10 square feet at 10 feet distance, or 100 units per square foot. This deduction, however, while apparently a logical one, is not correct, as may be seen from the following familiar illustration:

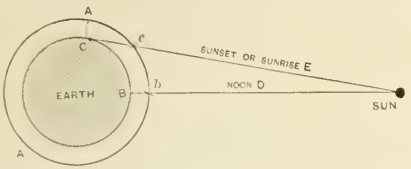
HEATING BY OPEN FIRES.

Take the case of a room heated by an open grate coal fire. It is well known that all of the air heated by actual contact with the fire itself is carried up the flue by the chimney draft. If this were not the case the noxious gases from combustion of the fuel would be disseminated about the room and render it untenable. As the only sources of atmospheric diffusion of the heat are radiation and contact of air, and the latter being rendered *nil* by reason of the necessary draft, we have to depend solely on the radiant heat for warming the room. Now, if it be true that there is no loss of heat by the rays in passing through the air to the walls, furniture, &c., it follows, necessarily, that the only heat available for maintaining the desired temperature in the room will be that which is absorbed by the air from contact with the surfaces receiving the radiant heat of the fire. That this cannot be so, however, is evident from the fact that if the walls of the room, as is usually the case, are exposed to a considerably lower temperature externally they are actually cooler than the air of the room, and consequently, instead of imparting heat to the latter, will absorb from it, notwithstanding that they are supposed to be receiving all of the effective heat from the fire. Under these conditions, then, what is the source from which the air derives its comfortable temperature?

That it is possible to heat a room comfortably by such a fire we know perfectly well from every-day experience; and that the temperature of the air corresponds is shown by the thermometer, by which also we find that the walls are cooler than the air. It would certainly seem that our deductions must be a matter of "Hobson's choice," and that the air is really heated by the diffusion of a considerable portion of the radiant heat in its passage from the fire to walls, &c., by which it is finally absorbed, not only without their contributing to the heat of the room, but actually abstracting from it by reason of their lower temperature. While this hypothesis is directly opposed to the authorities previously alluded to, its correctness may be readily demonstrated by actual thermometrical test; and we may safely accept it for use in our subsequent calculations.

Of course, when the atmospheric temperature is above that of the absorbent

the loss by the heat rays will be very slight, and, were it not for the comparatively high conductivity of the walls, which transmits the heat through them to the outer surface, they would soon become hotter than the air, and in their turn give off heat to the latter by contact, and to any colder body by radiation. This may be illustrated experimentally by placing a screen at say mid-distance between the fire and opposite wall, in which case the air on both sides of it (the screen) will be at the same temperature. The radiant heat from the fire will be absorbed by the material of the screen and transmitted



through its thickness with a rapidity due to its degree of conductivity, until its far side is of nearly the same temperature as that next the fire. Then, by holding a thermometer indicating the atmospheric temperature within a few inches of the far side of screen it will begin to rise and will indicate the temperature due to the radiation from the screen to the colder wall and the heat absorbed by the air from contact.

Of course, the same effect would be produced by perfectly insulating the walls externally with some non-conducting material, and thereby preventing the loss of heat from conduction. Its temperature would then rise and assist in warming the air by contact, and any colder body (the thermometer, for instance) by radiation.

RADIATION AND ABSORPTION.

It is important to note that the power of receiving or absorbing heat by all bodies is invariably the same as their radiating power—that is, they give and receive in the same degree. To illustrate, we may suppose a room located between two others, the temperature of the air and walls of all three being, say, 80°. If one of the outer rooms be then cooled off by admission of cold air, the partition wall will also become colder—say to 79°—and the opposite wall will then radiate its heat until the two temperatures are equalized. If, now, the equilibrium of temperature be restored to 80° and the other wall cooled by the same means as the first, the latter will radiate as rapidly as it had previously absorbed, and the now cooler one will receive exactly the same as it had before radiated. For this reason any nonconducter which will protect against heat is equally efficient against cold. In the first case it keeps the heat out and in the second it keeps it in. The loss of radiant heat by its passage through the atmosphere, from the radiant to the absorbent body, has been the subject of experimental observation, the results of which enable us to know definitely the amount of such loss.

HEAT FROM THE SUN.

For instance, the heat of the sun sensibly felt by us must of necessity be the radiant heat only. This is obvious, from the fact that the sun's distance from the earth (about 92 millions of miles) and the entire absence of any conducting or transmitting medium between the solar and terrestrial bodies prevents the possibility of any effect whatever from either conductivity or contact of air. These two quantities, then, being eliminated from the problem, we may attribute all of the effects of heat perceptible to us to the radiation from the sun as the only other possible source. Now, we know—everybody knows—that the sun is much hotter at noon than when it has just risen or is near setting. Yet there is no apparent reason for this being the case, unless the difference of temperature is due to loss of heat by the sun's rays from absorption by the atmosphere—the thickness of which varies in accordance with the relative positions of the sun and that point on the earth's surface at which the observer is located. The accompanying diagram will illustrate this fact and its cause and effect.

The small black disk represents the sun, the large shaded one the earth, and the circle A A surrounding the latter the boundary or limit of the atmosphere. The latter is known to be about 45 miles in thickness, and outside of its limit the space (called celestial) is boundless or infinite—a fact which is utterly impossible of realization by the human intellect. This space, save for the presence of the planets, stars and their satellites, with their surrounding atmospheres, is absolutely empty. It is devoid of air or gases of any description, and may be considered as a practically perfect vacuum, the effect of which will be alluded to as we progress. In the diagram the points B and C indicate the positions of the observer on the earth's surface, the former at noon and the latter at sunrise or sunset. The two radial lines from the sun to the earth represent that portion of the sun's rays falling on the observer at the two points of observation. Let us suppose now it is high noon, and our position will be at B. The sun's rays at this point, as represented by line D, are exactly vertical, and that portion between the points B and *b* shows that they reach the earth's surface by passing through the least possible extent of the atmospheric space—that is, 45 miles only—and consequently the loss of heat by the rays from absorption by the air must be the minimum at this position. Now, considering line E as the position to which the observer has been carried by the earth's revolution on its axis, or that portion of it between noon and sunset, we see that the rays, instead of falling vertically, as at noon, strike the earth's surface at a tangent, or obliquely, and that the portion of the line between the points C and *c* is several times longer than from B to *b*. The exact difference may easily be calculated, but it is unnecessary in this connection. It will be sufficient for our purpose if we assume the distance to be as 3 to 1, and that instead of traversing but 45 miles of air the sun's rays must pass through three times 45, or 135 miles.

This is the main cause of the difference of the noon and evening (or early morning) temperatures of the "sunshine." Of course the distance from the sun is greater at C than at B by nearly one half the earth's diameter, but as this would be but 4000 miles added to the 92,000,000, it represents so small a percentage as to be inappreciable in its effects. At this point, then, we have the maximum absorption by the air, and at any intermediate position the loss will be relative to that position.

But that atmospheric absorption is not the only source of loss of the radiant heat may be readily appreciated when we compare the highest temperature of the noonday rays in the hottest climates with the intense heat of the sun's mass. This is estimated to be sufficiently high to cause, in radiant heat alone, an effect equal to that of the combustion of 20 tons of coal per day for each square foot of the sun's surface, or 2000 tons for every 10 feet square. This would be equal to a mass of coal about 600 feet deep on the entire surface. Owing to the great distance and comparatively small size of the earth, the proportion of the total amount of the sun's radiant heat received by the former is estimated to be but $\frac{1}{2000000000}$.

NEW PUBLICATIONS.

FOURTEENTH ANNUAL REPORT OF THE BUREAU OF STATISTICS ON LABOR AND INDUSTRIES OF NEW JERSEY. James Bishop, Chief of Bureau, Trenton, N. J.

A voluminous report, covering over 600 pages, conveys some interesting data concerning labor legislation in New Jersey and other matter relating to industrial occupations and associations in that State for the year ending October 31, 1891. The bureau has diligently recorded a considerable mass of labor legislation and the decisions of the higher courts of New Jersey in interpretation of the rights and duties of workmen. The latter is a new feature in the report, and one of considerable interest. Among the legislation of special note recorded in the document are the acts creating a State Board of Arbitration, and a commissioner for the inspection of mines, the law limiting employment in factories to 55 hours per week, the modification of the mechanics' lien law amendment of 1890, and the anti-Pinkerton act, all of which are of some moment in relation to the labor question. More than half the volume is devoted to a consideration of the co-operative building and loan associations of New Jersey, the results of extended inquiry into the operations of these societies being presented in a series of tabulated forms. The reports show 271 co-operative associations of this character to have been in existence in 1891, as compared with 254 in the previous year. The net assets of these State enterprises amounted to over $25,000,000, an increase of $3,500,000. The remainder of the document gives the results of the third year of inquiry into the effect of occupation on the health and working life of those engaged in a number of industrial pursuits. For the year under review the investigation has taken in 13,000 journeymen, employed as carpenters, painters, bricklayers and masons, stonecutters, plumbers, printers, glassblowers, hat finishers, miners of iron ore and potters—a fairly representative selection of industries. Tables annexed to this section give ages when journeymen began to work, present ages, ages of decline, number of years at work and diseases from which incapacitated. Of these trades carpenters and bricklayers come out, as might be expected, on the top, followed by potters and miner, while glassblowers and printers show the most unfavorable results.

A migration of negroes from East Tennessee and other parts of the South has commenced, not unlike that noted a year ago, when many started for Liberia. This time they are going West, some to Oklahoma. The only trouble is in stopping. In several localities vigilance committees have been formed, who order the negroes to "move along."

The American Santo Domingo Improvement Company have entered upon their work of collecting the customs revenues of the Black Republic and will take prompt measures to suppress smuggling and all official crookedness.

ROOFING AND CORNICE.

The Country Cornice Shop.

V.

By Cornice Worker.

OBTAINING WORKING MEASUREMENTS.

Having understood how the snow-guard gutter is to be constructed, the measurement and bevel of roof must now be obtained from the building. Brass and wooden bevels can be purchased from hardware dealers, but a bevel constructed of band iron will answer just as well.

In Fig. 42 is shown what is required to construct a bevel of band iron. Let A represent one of the two pieces of band iron, with a ¼-inch hole punched and countersunk, as shown at D, to receive the rivet, and B the section. C represents a ¼ x ⅝-inch rivet, which is used to rivet the two pieces of band iron together. Care should be taken that when the two arms are riveted together the one is exactly like the other and that the end E is perfectly square.

When the bevel is finished and is in use it will look as shown at L, in Fig. 44.

Fig. 43 is the front elevation of roof and gutter, also showing the method of obtaining the working measurements.

Let the width of the building on which the gutter is required measure 42 feet, as shown, and as the leader P is to be in the center of the building, divide the width by 2, and 21 feet on each side is the result, as shown. The pitch or fall of the gutter will come directly over the leader, as shown by X, Fig. 43.

From the point X, Fig. 43, or the lowest point of gutter, strike a chalk line parallel to the eave line, as shown by the

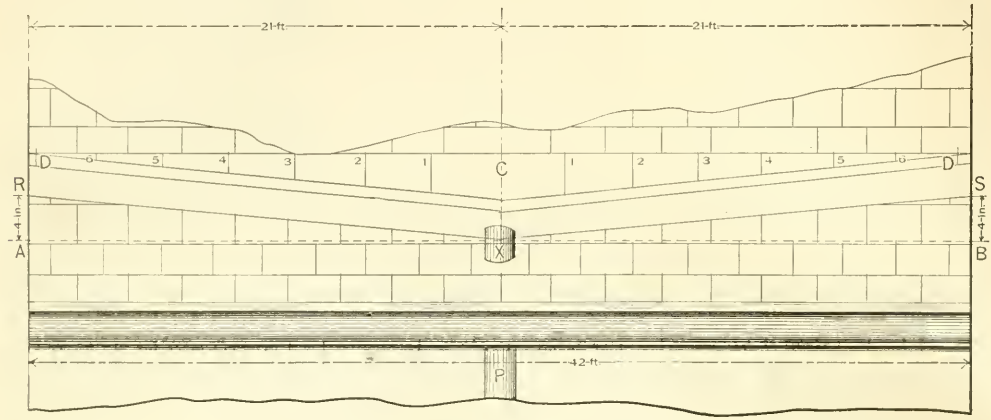


Fig. 43.—Front Elevation of Roof and Gutter.

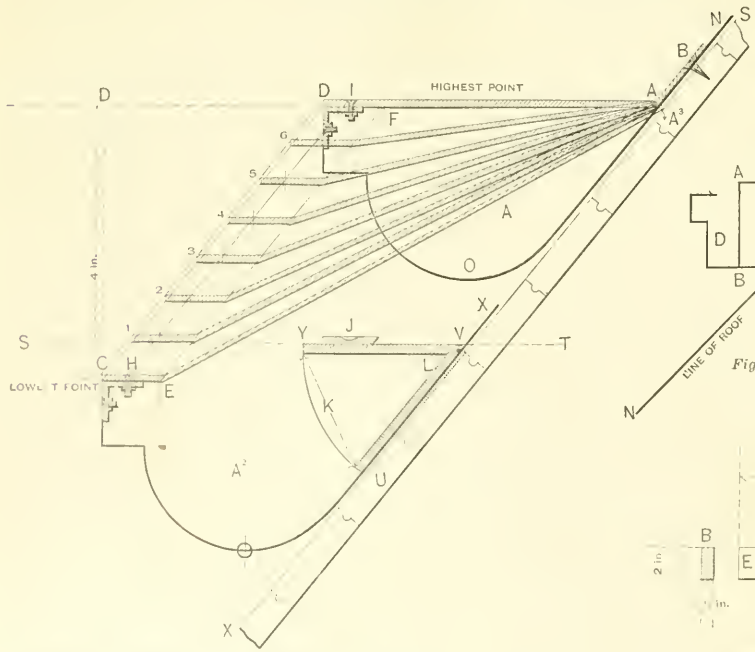

Fig. 44.—Method of Obtaining the Different Lengths and Angles of Top Braces.

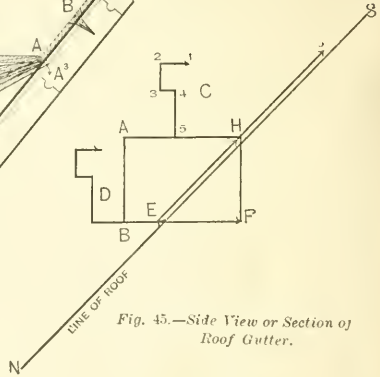

Fig. 45.—Side View or Section of Roof Gutter.

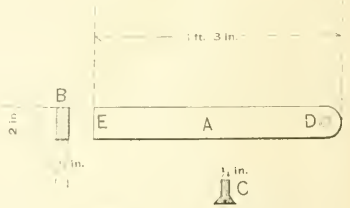

Fig. 42.—Rivet and Band Iron for Bevel.

dotted line A B. At right angles to the line A B, on either side, measure up 4 inches, or the pitch of the gutter, on a perpendicular line, as shown by R and S, Fig. 43. Now strike a chalk line, S X and X R, which gives the bottom line of the gutter, shown on the section in Fig. 44 at O. The line R X and X S would be struck on top of the slates, or whatever the covering of the roof may be, and upon this line the bottom line of the gutter would be placed.

Having now obtained the length of each side of the gutter, the next step is to obtain the bevel of the roof. To do so, place the bevel as shown by U V Y in Fig. 44, the arm U V being placed against the roof and the other arm V Y being raised or lowered until level, which can be proven by screwing a small spirit level on the arm, as shown at J. Now measure the distance between the arrow points K, and the bevel can be closed and opened again when required to the distance before obtained. This bevel forms the basis of measurements required to construct the different braces shown in Fig. 44.

In setting up work of this kind it is well to make a rough diagram, similar to Fig. 43, showing the braces required and their numbers, also the pitch the gutter is to have, for the use of the mechanic who sets up the work. As the braces are of different lengths (to obtain a straight line, as shown from D to D in Fig. 43), each brace will be numbered in the shop to correspond to the numbers shown, on the braces in Fig. 43 by C, 1, 2, 3, 4, &c.

OBTAINING THE DIFFERENT LENGTHS OF BRACES.

In Fig. 44 is shown the method of obtaining the different lengths and angles of braces. Draw any horizontal line, as shown by S T, indefinitely, upon which place one arm of the bevel Y V; now open the bevel to the length obtained between the arrow points K, as before explained, and draw a line parallel to, and against the arm of the bevel U V, as shown by X S. Then X' S' will represent the roof line and S T the horizontal or level line, corresponding to the bevel U V Y. Now draw a section of the gutter, as shown by A, Fig 44; care being taken to have the top of the flange of the gutter, as shown at N, high enough above the top of the front of the gutter, so that in case the leader stops up, causing an overflow, the water will flow over the front of the gutter, and not behind the flange N and into the building.

As the pitch of the gutter is 4 inches on a perpendicular line, as shown in Fig. 43, measure down 4 inches from D to C, Fig. 44, and draw a duplicate of the section of the gutter A', as shown by A^2. Then D will represent the highest point of gutter and C the lowest point, as shown. The sections of angle iron, with bolts through the top braces, are shown at I and H. Draw the brace at the highest point of gutter horizontal, as shown from D to A, with an angle attached to screw to the roof board, as shown from A to B. Then draw the brace for the lowest point of gutter horizontal from C to E, or as much as there is flange on the top of the gutter. Connect the points from E to A^2 and add the thickness of the brace, as shown, which in this case is $\frac{3}{16}$ inch.

Then D A B, Fig. 44, will represent the top brace D, Fig. 43, and C E A^2 B the center or bottom brace C, shown in Fig. 43. As the pitch of the gutter is 4 inches and the projection of the roof on 4 inches as much as shown from D to D', Fig. 44, and as there are eight braces required on the 24 feet of gutter, as shown by C, 1, 2, 3, 4, 5, 6 and D in Fig. 43, it is self-evident that each brace will be of a different length and angle.

To obtain the different lengths and angles proceed as follows: Draw a line from C to D, Fig. 44, as shown, and divide this line into seven spaces or as many spaces as there are shown between the

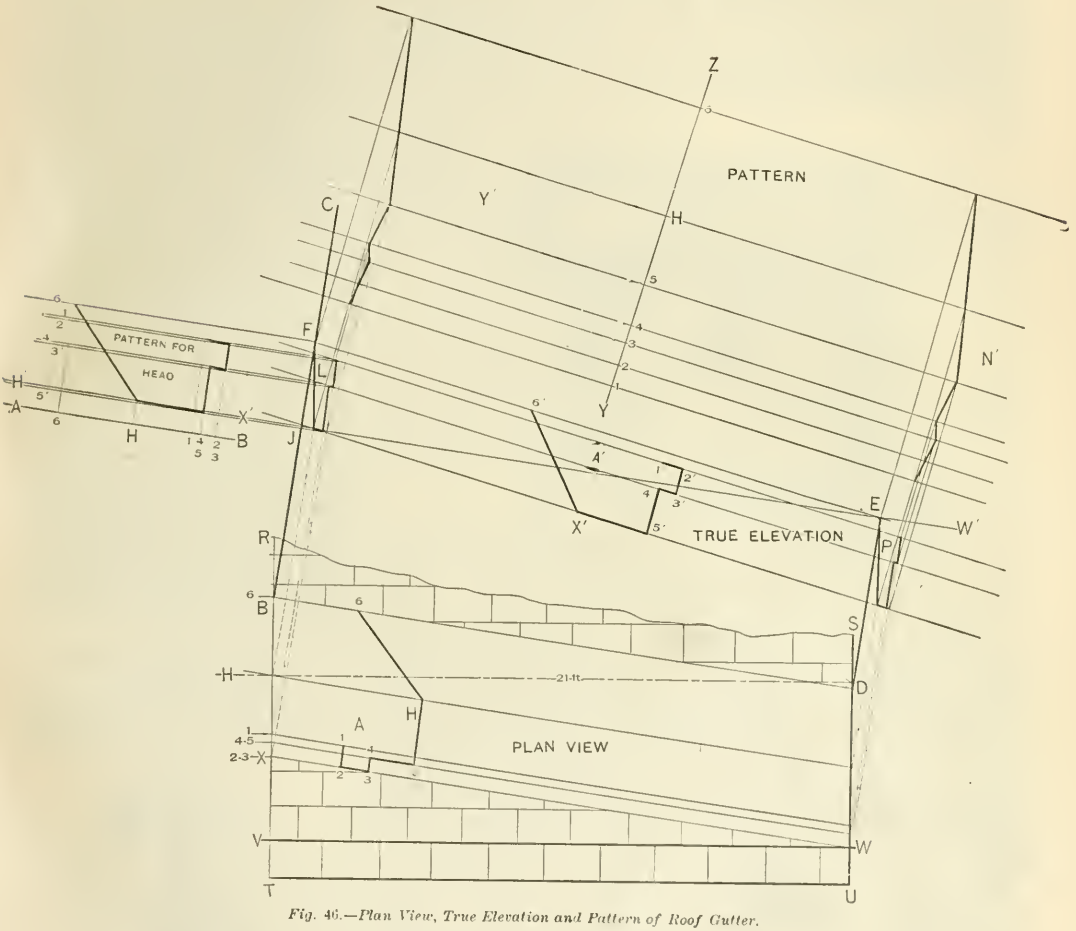

Fig. 46.—Plan View, True Elevation and Pattern of Roof Gutter.

THE COUNTRY CORNICE SHOP.

braces in Fig. 43. Now draw a line from E to F, which intersect with horizontal lines drawn from the small figures on the line C D. From the intersections obtained on the line E F draw lines to the corner A. Now add the thickness of the brace, as shown, and draw lines parallel to the horizontal lines 1, 2, 3, 4, 5 and 6, intersecting the line E F, and from these intersections draw lines to the corner A^3. Then the braces C, 1, 2, 3, 4, 5, 6 and D in Fig. 44 will represent the braces used on each side of the gutter of corresponding figures shown in Fig. 43. A line drawn from H to I, Fig. 44, will give the points where the holes are to be punched for the bolts; the angle A B will be the same length on all the braces.

After the braces are bent to the required angle and numbered, they are usually galvanized to prevent rusting; the angle iron also is usually covered with two coats of metallic paint before it is inserted in the gutter.

OBTAINING THE PATTERNS.

Fig. 45 is a section of a roof or snow-guard gutter, the bends of which have been made square, so as to avoid a confusion of lines in obtaining the patterns; although the principles used are the same no matter what form or shape is taken. To obtain the plan and elevation proceed as follows: Let N S, Fig. 45, represent the line of roof; C, the highest section of gutter, and D the lowest section. Let A B or H F represent the pitch of the gutter on a perpendicular line and E F the projection of same. Let R S U T, Fig. 46, represent one-half of the plan of the roof, the width of same being 21 feet. Now draw any line parallel to the eave line of roof or T U, as shown by V W; take the distance of the projection of the gutter, shown by E F in Fig. 45, and place same at right angles to V W, as shown by V X, Fig. 46. Now draw a line from X to W as shown. At right angles to the line X W place in the proper position, as shown at A, a duplicate of the profile or section of gutter shown at C or D, Fig. 45. Number the bends of the profile A, Fig. 46, as shown by the small figures 1, 2, 3, 4, 5, H and 6. Now parallel to the line X W draw lines through the numbered bends, cutting the lines R T and S U, as shown. Parallel to the line X W draw a line indefinitely, as shown by X' W'. At right angles to the line B D in plan draw lines upward from B and D indefinitely, as shown by B C and D E, cutting the line X' W at the points J and E. Now take the pitch of the gutter, as shown by A B or H F, Fig. 45, and transfer this hight from the point J on the line B C, Fig. 46, as shown by J F, and draw a line from F to E. Then F E will represent the line of the gutter in the true elevation on the point 6 in the profile A in plan view. Now place a duplicate of the profile or section C, Fig. 45, or profile A in plan view, Fig. 46, as shown by A in true elevation, the small figure 1, 2, 3, &c., of profile A, corresponding to the small figures shown in plan view. Through the small figures 1, 2, 3, &c., in profile A in true elevation draw lines parallel to the line F E, which intersect with lines of corresponding numbers drawn at right angles to the line X W from the intersections made on the lines R T and S U, all as shown. A line traced through these intersections, as shown by L and P, will show the true elevation and miter lines of roof gutter.

To obtain the pattern, proceed as follows: At right angles to the line F E lay off the stretchout of the profile A, Fig. 46, as shown by the small figures from Y to Z. At right angles to Y Z, or parallel to F E, draw lines indefinitely through the small figures in the stretchout, as shown, which intersect with lines drawn at right angles to the line F E from the intersections on the miter lines L and P of corresponding numbers. A line traced through the intersections thus made will be the required pattern.

To obtain the pattern for the head of the gutter shown at R and S, Fig. 43, proceed as follows: At right angles to the line B C, Fig. 46, draw lines from the intersections on the miter line L. It will be noticed that these lines are numbered 5', H, 3', 4', 2', 1' and 6', corresponding to the same numbered lines, drawn through the profile A', in the true elevation. At right angles to where the gutter intersects the line X B, plan view, Fig. 46, draw short lines, as shown by 2, 3, 4, 5, 1, H and 6, corresponding to the same numbered lines drawn through the profile A in plan view. Now parallel to the lines drawn at right angles to B C, draw a line, as shown by A B', upon which place the widths, as shown by 2, 3, 4, 5, 1, H and 6, corresponding to the intersections on the line X B, plan view, as shown by 2, 4, 5, 1, H and 6. Then at right angles to A' B' draw lines upward from the small figures, as shown, intersecting lines of corresponding numbers drawn from the miter line L, at right angles to B C. A line traced through these intersections will be the pattern for the head of the gutter required at R and S, Fig. 43.

To avoid any misunderstanding, it is well to remark that the sections shown at C and D, Fig. 45, do not represent the true sections on the lines R T and S U, plan view, Fig. 46, and are only drawn to form a basis from which to obtain the measurements of the pitch and projection of the gutter, and are sections of the gutter at right angles to B D, plan view, and sections at right angles to F E, true elevation. The pattern for the head of the gutter, shown in Fig. 46, is the true section of the gutter on the line R T and S U, in plain view.

SUBDIVIDING THE MEASUREMENTS.

In practice it would be impossible to lay out a drawing of 21 feet on the ordinary drawing board, although the gutter could be laid out on the floor. To avoid this and to make use of the drawing board, the entire measurements could be divided into eight parts or less, according to the length of the drawing board in use.

The following explanation is given to illustrate what is meant by dividing the measurements: By dividing the measurements into eight parts, instead of laying off 21 feet, as shown from V to W, Fig. 46, take one-eighth of same, which is 2 feet 7½ inches, and make V W equal to 2 feet 7½ inches; then instead of making V X, Fig. 46, the projection of gutter, as shown from E to F, Fig. 45, make it one-eighth of E F. And having obtained the line X' W' in true elevation, Fig. 46, instead of making J F equal in hight to A B or H F, Fig. 45, make it one-eighth of the distance. By dividing the length, projection and pitch of the gutter each into the same number of equal parts, the same angles are obtained as in the full-size drawing.

SHORT RULES.

It is also proper to remark in this connection that, if but one gutter was being put up, it would hardly pay to get out the patterns as above described, as the time involved in obtaining the patterns would cost almost as much as the amount a small gutter would bring. In such a case, the gutter would be made a few inches longer than the desired length and placed on the roof in its proper position, and tacked with a few roofing nails. Then take a carpenter's square and place the long arm on the roof parallel with the eave line, and, holding the short arm of the square perpendicular, mark off a perpendicular line on the top and bottom ends of the gutter where required, and trim with the hand-shears or snips. Then the lower cut will represent the miter line on which the second piece of gutter would be joined, and the top cut may be used to obtain the pattern for the flat head, by simply holding a piece of galvanized iron or other metal against same and marking off the shape.

It is, however, a good plan to obtain accurate patterns, as described, which are saved for future use; and when a gutter of this style is required, it can be given the same shape and pitch. Thus the same patterns can be always used, it only being necessary to obtain the amount of pitch required on every gutter of a different length, so that a chalk line indicating the pitch can be struck on the roof on which the bottom line of the gutter is placed.

Now, as above described, if a gutter of 21 feet has 4 inches pitch, then a gutter of 10 feet 6 inches would have but 2 inches pitch, or in other words, the gutter would have a fall of $\frac{4}{21}$ of an inch to the foot. As $\frac{4}{21}$ makes the figuring complicated, ½ inch fall to the foot could be given and the patterns cut accordingly. This would make the pitch on 21 feet equal to 5½ inches. In case a gutter was required measuring 21 feet 5½ inches, it would be necessary to obtain the amount of pitch required for the 5½ inches in length. To obtain this without tedious figuring, construct on a piece of heavy white cardboard, for future reference, a triangle whose base is 12 inches in length (divided into half and quarter inches) and the altitude or perpendicular hight as much as the fall of the gutter is to the foot, which in this case is ½ inch. Connect the altitude and the base by a line called the hypotenuse or slant line, which completes the triangle. From the divisions on the base of the triangle, draw lines at right angles, intersecting the hypotenuse, or slant line. Then place one leg of the dividers on the 5½ inch division on the base, and the other leg of the dividers at the point where the 5½ inch perpendicular line intersects the hypotenuse; then the distance between the points of the dividers will be the amount of pitch required for the 5½ inches of gutter. This rule applies to any measurements whatever.

Berger's Standing Seam Snowshoe.

Berger Brothers of 237 Arch street, Philadelphia, Pa., have just brought out a novel device which is intended to do away with either snowrails or gutters formed on roofs to prevent snow from sliding down. The construction of the device is such as to avoid the necessity of boring holes through the metal or in any way cutting the roof for the purpose of providing suitable fasteners for snowrails. The construction is so clearly illustrated in the accompanying engraving that a lengthy description would appear to be unnecessary. The device is made of malleable iron, and can be clamped directly to the standing seam by the use of an ordinary pair of tongs, the teeth of the side being forced through the seam into corre-

Berger's Standing Seam Snowshoe.

sponding holes on the opposite side. The manufacturers state that when no suitable tongs are conveniently at hand, an ordinary hammer can be employed to bend the clamps into proper position. The manufacturers refer to the standing seam snowshoe as being convenient and economical. The statement is made that if the snowshoes are placed reasonably close together no rails will be necessary.

FLASHINGS.

THE AMERICAN ROOFING COMPANY of St. Louis, Mo., and Cincinnati, Ohio, have just issued from the press a catalogue of something over 60 pages, printed on calendered paper and bound in colored paper covers. This, we understand, is the company's fourteenth series of publications, and within its covers are presented illustrations of a variety of products showing the different uses to which sheet metal has been applied in the construction and adornment of all kinds of buildings. The statement is made that during the past ten years the company have filled many orders for sheet metal made into such forms as steel pressed brick, corrugated siding and ceilings, sheet metal clapboards, iron and steel roofing, galvanized iron cornices and curved awnings. The descriptive letterpress is ample for the purpose, while the illustrations are of a character to show very clearly the special features claimed for the goods turned out by the company. Several diagrams are given to facilitate the ordering of roofing and siding, while a comprehensive index renders reference easy.

AMONG the many patents issued by the Patent Office on February 28, 1893, was No. 492,513, granted to Alvin C. Kanneberg of the Kanneberg Roofing Company, Canton, Ohio, for an improvement in sheet metal roofing. The issuance of this patent, we understand, has been strenuously contested in the Patent Office, there having been two interferences and five hearings, all of which were decided in favor of Mr. Kanneberg. The Kanneberg Roofing Company have recently enlarged their plant and now occupy the entire block between Oak street and the electric light station on East Seventh street, and have now a factory fully equipped with modern machinery for the manufacture of all kinds of steel and iron roofing, siding, ceiling, metallic shingles, eave trough, conductor pipe, &c.

Travelers' Samples Not Baggage.

A decision of very general interest to manufacturers and others affected was recently handed down by the Supreme Court of New York, in connection with the responsibility of railway companies in the matter of samples carried by commercial travelers. The gist of the decision is that the ordinary contract of a railroad company or other common carrier of persons is to transport them and a certain amount of their personal baggage, and not the merchandise of other people. Samples of merchandise contained in the trunks of commercial travelers, and belonging to their employers, do not constitute a part of their legitimate baggage. Consequently where such samples are checked as baggage over lines on which passage is taken, and especially as the baggage of the commercial agents, no recovery can be had for their loss. Nor does the mere fact that an excess baggage charge on extra weight is demanded and paid and the fact that the baggage agents are informed that the trunks checked contain samples change this. Though if the carrier undertakes, by express or implied contract, to carry other people's merchandise as freight, they are liable as any common carrier of freight would be, and that is all; and such facts must appear from which it can be reasonably inferred that this contract of affreightment was entered into with knowledge of all the facts.

In commenting upon the case, a leading railway journal remarks:

"If, as it appears by the decision, a railroad is not responsible for commercial travelers' samples as baggage, there will be an immediate and urgent need of providing for some arrangement under which these samples may be carried. There is no doubt but that our system of baggage transportation has been so misused by commercial travelers as to amount to a veritable abuse, and it is just possible that in view of the decision railways may find it to their advantage to refuse to longer engage in what actually amounts to express business, and refer commercial travelers to such companies for the transportation of their sample cases which, in many instances, exceed a thousand pounds per traveler."

That there is much justice in these remarks will be acknowledged. At the same time it is their obvious duty to make such arrangments that a commercial traveler may be able to accompany his sample cases, which it is often undesirable to consign to the care of express companies on account of delays, not to speak of the heavy charges imposed by those carriers.

The Stover Power Hack Saw.

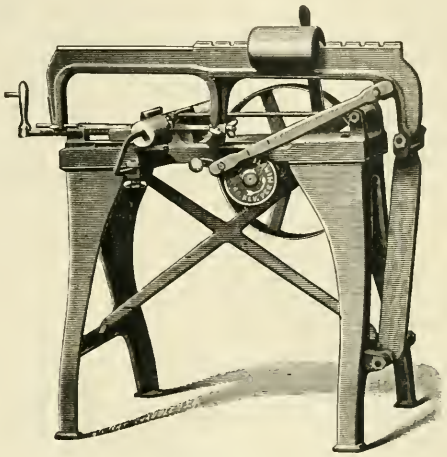
The power hack saw here illustrated is made by the Stover Novelty Works of Freeport, Ill. The machine cuts any size or shape of metal up to 4½ inches, and is provided with a vise for holding the work to be cut. The frame carrying the saw is pivoted at one end to a bar journaled in the lower part of the frame. The upper bar of the saw frame is notched and adapted to receive the weight by which the pressure of the saw on the work is adjusted. It will be observed that, owing to the point at which the upper end of the pitman joins the saw frame, the pressure during the forward or cutting stroke is much greater than on the return. When the bar has been cut off the machine automatically lifts the saw from the work and stops.

Manitoba farmers demand that American agricultural machinery and barbed wire shall be admitted free of duty.

Position of British Gas Companies.

On the subject of gas lighting in Great Britain, the London *Times* says:

Judging from the annual Parliamentary returns just issued relating to gas undertakings in the United Kingdom, the companies have not yet been seriously affected by the adoption of the electric light. Indeed, the gas companies still continue to be steadily progressive and fairly remunerative. The number of public companies last year was 410, as compared with 405 the previous year and 394 in 1889, and the total capital sunk in gas undertakings has risen from £59,878,000 in 1889 to £63,620,000 in 1891. About two-thirds of this large total, or £41,144,000, represents the capital belonging to public companies, the remainder being the capitalized value of the undertakings belonging to local authorities. Both classes of undertakings exhibit an increase in business. The number of cubic feet produced by the companies last year was upward of 70,000,000, as compared with 67,000,000 the previous year and 61,500,000 in 1889. There was even a larger increase in proportion in the number of cubic feet produced by local authorities. Customers do not increase in a like degree, although in 1891 there was an addition of 55,759 to the number of consumers supplied by the two classes of undertakings. An addition of 14,700 was made to the number of lamps erected for the illumination of public roads. The gross receipts of the companies increased during the year by rather more than £1,000,000, and the quantity of coal carbonized by 977,000 tons. Owing to the growth of expenditure, net profits have fallen from an average of 11.71 pence per 1000 cubic feet in 1888 to 9.15 pence in 1891. The average dividend has consequently fallen from £8 11/0¾ in 1889 to £8 7/10¾ per £100 in 1891.



THE STOVER POWER HACK SAW.

A bill has been introduced into the British House of Commons to compel the marking of files to show distinctly whether they are hand-cut or machine-cut. This measure has been brought forward in consequence of a fraud recently imposed upon the Admiralty Department. A contract for 11,000 dozen of files was placed by that department on the condition that they should all be hand-cut. It was afterward discovered that nearly 3000 dozen, or over one-fourth, were machine cut.

"The Metal Worker" Competition in Skylight Pattern Cutting.

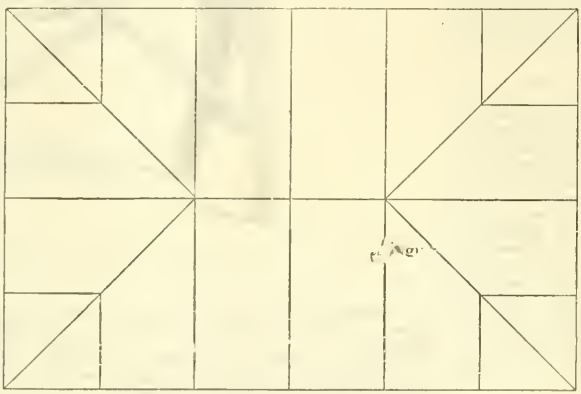
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

The Foundrymen's Association.

The regular monthly meeting of the Foundrymen's Association was held at the Manufacturers' Club, in Philadelphia, on Wednesday evening, March 1, with a large attendance of members.

The Executive Committee reported that the subject of coke for foundry use was an important one, and it was their wish to continue the discussion and invite representatives from different sections of the country to instruct the foundrymen regarding the adaptability of coke for fuel in the cupola in comparison with coal. The address by Jones Wister has been largely appreciated, and a number of letters received by the Secretary asking further information. Nine new firms were elected to membership in the association.

A discussion then took place in regard to the forming of sections in the association, according to the kind of casting made. There are seven or eight branches of the foundry trade, and a committee representative of each branch has been appointed for the purpose of reporting the current prices for castings, in order that members of the association may know the actual market price. The committee are also to endeavor to get the respective foundries making the same class of castings together to talk over the possibilities of improving their condition, in the hope of effecting an ultimate arrangement for procuring better prices. The cutting of prices and the ill feeling existing in consequence was a serious bar to legitimate business.

P. D. Wanner of the Mellert Foundry & Machine Company, Reading, Pa., cast-iron pipe manufacturers, in the course of the discussion, said that cast iron pipe was being sold at ruinously low prices; lower than it had ever been sold before. During the panic of the '70's the cast-iron pipe trade held its own exceedingly well until 1877. In 1877 the prices broke, and in 1878 particularly so. Then came the rise in pig iron, and the pipe trade was interfered with; but during that depression, lasting two or three years, part of 1876, 1877 and 1878, it swamped or seriously embarrassed nearly all the pipe founders then in business, and the pipe was sold at the lowest prices then ever approached. The regular class of pig iron was sold at the same price as now quoted, and Northern iron was to-day very close to the price of 1877 and 1878. He drew attention to the depression in the pipe trade experienced for nearly five years, since 1877, and referred to the prices as being so very low that everybody in the trade should cease selling. He believed that during the last five years of depression there had been almost enough work to go around. If some of the other pipe manufacturers had taken the course he did (he had three pipe foundries and closed two of them) they all would have been able to get good prices; but he considered that some in the trade were simply running the business for the love of it. There was a letting recently in which there were four bidders. He was informed that three of them struck as low as they dared—probably the danger line—and the one taking the job went from $3000 to $3500 below that. He was of the opinion that the appointment of a trustee was in order for a man putting in such a wild bid; any person in any trade committing such an act was incompetent for business. Sometimes a man running in a special line might bid low as it was necessary for him to keep one or more of his shops running. In emergencies like these a man could to some extent be excused. But there was no emergency in the case he had mentioned. He admitted that every one in this country who was down to cost, and had been selling at cost for some years, should stop. A concern could not live by selling at cost. A profit must be made in a business if a living was to be taken out of it. There were emergencies which would occasionally occur, such as awards of damages to workmen, fires, bad debts, and others. These could not be met if business men figured to sell at cost.

George P. Smyser of E. G. Smyser's Sons of York, Pa., said that in his opinion it was best not to get reports on prices at present, but to get the different lines represented in the association together. Personally, he would first attach himself to the section covering architectural work, and afterwards to any other section in which he was at all interested. As an example of the low prices of accepted contracts he instanced the offer to him of a contract for iron columns if he would take it at $1.60, but he promptly refused. He afterwards learned that the contract was given out at $1.47½ for delivery alongside building. In his opinion the sooner an understanding between manufacturers was arrived at the better for the whole trade. He did not mean that, in making up the sections for committees, they should become separated from the association, but that the sections should act as committees and report to the association as a body.

S. C. Flagg, Jr., of Stanley G. Flagg & Co. of Philadelphia, thought it would be in vain for any one to attempt to give, for the purposes of the association, any prices, except on castings in specified classes of work. He had hoped to get from the committee an expression of the different prices at which certain castings could be sold. He considered that if a foundryman had no method of calculating his cost an unsatisfactory price could only be the result. Everybody must have an idea as to the amount of profit desired to be gained, and if costs were known it was easy to put the profit on them, and thus make a basis on which to compare prices with costs. When a man in the jobbing business mentioned what he got for his castings the information was valueless. In the matter of car work he found he could not compete with the prices in the West. He had asked a concern in Detroit what they would make castings for, and was quoted 3.25, delivered in Philadelphia. He had seen quotations on iron pipe and had been surprised at the difference in them, from $\frac{1}{10}$ cent to ½ cent. He thought that for association purposes prices of certain kinds of work might be of use, as he did not believe that two foundrymen in the same town and on the same class of work could differ much in costs. It was his opinion that many quotations showed an utter ignorance of costs.

The president, C. Schuman, was of the opinion that if iron pipe is made for 1 cent and other regular goods for nearly 1 cent less than in Philadelphia, it seemed high time for concerted action in the different branches of the trade. He thought each member should unite with the other members in his particular line and form a section, and promised that as regards his own line it would be done within 48 hours. He urged that mutual push would accomplish much, and expressed his belief that no one would get excessive prices at this day, for if they did other foundries would go into the business.

Justice Cox, Jr., stated that history generally repeats itself. He had no doubt some of the gentlemen present remembered the association of wrought iron pipe men in this country, especially in this city and in Pittsburg. A few years ago it was the most profitable business in the United States. Theirs was an association that fixed prices, and it held together for 10 years, and represented the most successful people in the iron business in the country. To day they were the most unsuccessful. They were selling lap-welded and butt-welded pipe at prices that would astonish any man in the same business 10 years ago. These people were at the present time cutting each other's throats, and they numbered only 21 concerns in the whole country. He drew attention to the manufacturers of rails as representing the most successful iron and steel workers of the day because they had an association. All knew that if they wished to buy rails in Chicago they were $29 for 50-pound rails and heavier, and if in Baltimore, the same price, as also in Steelton or Johnstown. He considered that the foundrymen were doing right in forming this association. As was well known, there were only a few concerns making columns, and comparatively few making pipe, and it would be a simple thing, with a little push and determination, to make an association a success and a means of material help to all. He belonged also to the Plate Association of Pennsylvania, which had had several meetings and had succeeded in getting prices to a fair profit until one of the large concerns in the vicinity went into a special kind of steel manufacture and lost a great deal of money, the result of which he thought all knew. That business is now in the same condition as the lap-welded pipe business. Everything in this country pointed to associations or to understandings that they should all make a little money. Through the Foundrymen's Association he believed better prices could be arranged, as there would be just as much business at higher prices as at lower. For purposes of information he would instance the method adopted by the wrought-iron people a few years ago. When an inquiry was out for a lot of iron pipe for a pipe line, the different concerns would ascertain when it was out and would all bid. The tonnage would then be divided among them, equitably, according to capacity for small and large work, thus holding prices and giving all concerns work enough to keep them busy. He explained the application of similar methods to the foundry business. He said that the association of the wrought-iron people collapsed through greed. They advanced their prices to such an extent that a concern went into the business at Catasauqua, and when the factory was half built the association bought him out at a ridiculous price. Another concern started at Chester, but the association this time decided to close it out, and this proceeding kept others out of the business and proved that low prices were their best protection. In spite of all they grew from 10 to 15 concerns, until to-day we find 21, which number accounts for the position they are found in to-day. In conclusion, he advocated the formation of sections in the association and the adoption of a plan for the division of work.

Thos. Devlin of Thos. Devlin & Co.; Mr. Rebman of G. Rebman & Co.; Mr. Whitney of A. Whitney & Sons, and others also joined in the discussion.

It was finally resolved that the price committee should be empowered to call upon other members to form sections in the different lines of the foundry business and report to the next meeting.

Manager Hughes of the Ward Line of steamships is not in the least discomfited by the financial difficulties of the Brazil Mail Steamship Company. He does not find in the fact any evidence that American steamship lines cannot succeed.

The ships of Admiral Gherardi's squadron, in returning from the Pacific, were retarded 2 knots an hour compared with the start, by the accumulation of barnacles on their bottom. Believers in sheathing know of only one remedy for this difficulty. The cost of fuel to bring these ships around from San Francisco is said to have been $200,000.

PLUMBING AND GAS FITTING.

New York State Master Plumbers.

THURSDAY'S SESSION.

The Master Plumbers' Association of the State of New York opened its fifth annual convention at the City Hall, Albany, N. Y., March 2, at 10.30 a.m. President John A. Rossman of New York called the delegates to order.

The president's address was quite an informal one, but delivered to the point. He said that the organization was in a prosperous condition and that success was attending its efforts toward the betterment of all things pertaining to the plumbers' trade. He said the society is always ready to receive new ideas and suggestions in regard to sanitary improvements in plumbing. The health of great communities depends upon the skillful work of the plumber. He referred to the excellent sanitary condition throughout the State of New York, and added that a great part of it was due to the plumbers' handiwork.

The delegates, 75 in number, wore handsome satin badges with neat *boutonnières*. The officers in attendance were: President, J. A. Rossman of New York; vice-president, J. Edward James of Albany; secretary, William J. McDermott of New York; financial secretary, G. Alfred Smith of Brooklyn. Treasurer J. H. Bradish of Batavia was absent.

President Rossman next announced the Committee on Credentials, composed of 15 delegates selected from local associations for that purpose. After some discussion the convention decided to continue in session, instead of adjourning pending the report of the Committee on Credentials. The resignation of J. H. Bradish of Batavia as treasurer, on account of sickness in his family, was announced by the president.

After a short recess the convention was again called to order, when the Credential Committee through its chairman, Henry E. Weber, reported. Having gained the consent of the Executive Committee, President Rossman announced as Treasurer Bradish's successor James B. Lewis, and the appointment was ratified.

Messrs. Collins of New York, Stahl of Albany and Murphy of Troy were named as an Auditing Committee and an adjournment was taken until 2 p.m.

At 2.35 p.m. the convention again assembled, and several new delegates reported. A communication was received from Jeremiah Sheehan of St. Louis, president of the National Association of Master Plumbers, requesting the affiliation and representation in the National Association of State associations. After a few remarks by President Rossman on the need of conducting business systematically, the meeting went into executive session.

In his annual address President Rossman thanked those who had helped the association get its bill through the Legislature. He earnestly urged the adoption of a plan for establishing training schools for apprentices. The members were requested to do what they were able as individuals to make the annual meetings interesting and profitable. The president said he would like to hear debates at future sessions on topics for the good of the craft.

In the evening the delegates, with a number of guests, held their annual dinner. The tables were attractively arranged and loaded with good things. There was enjoyable music, and a merry spirit among them all. Horace F. Westcott of Albany made a graceful toastmaster, and all of the speeches were informal, but none the less witty and enjoyable. Among those who responded were: John Creelman of Rochester, W. N. Tobin of Saratoga, H. G. Gabay of New York, Thomas H. Radcliff of Brooklyn, William McDermott of New York, Edwin Haywood of Brooklyn, J. A. Rossman of New York, Herman H. Russ of Albany.

FRIDAY'S SESSION.

It was nearly 11 o'clock Friday morning when the convention reconvened. J. F. O'Neil of Oneonta presented his credentials and was admitted. Several communications were received, among which was one from Hon. John K. Alden of Chicago, congratulating the association on securing the enactment of the new Plumbing law.

A number of claims were next considered, among which was the expense attending the passage of the new State Plumbing law.

State Superintendent of Buildings Delehanty was presented to the convention by Herman H. Russ of Albany, and was welcomed. Superintendent Delehanty invited the association to visit the Capitol, the grandest building in the country, which the delegates did later. Mr. McDermott moved that a plumber having passed an examination and secured a certificate, need not undergo another examination upon his taking up his residence in another city. It was decided to refer this matter to Attorney-General Rosendale to determine whether the motion, if adopted, would conflict with the State law. A resolution was made and adopted that any effort to secure change or amendment of the State law must be made through the State association.

The secretary reported that the dues recived from 18 associations amounted to $164.55, and from individual members, $12. Four associations joined during the year: Schenectady, Yonkers, Auburn and Poughkeepsie. The individual members who had joined were from Mount Vernon, Shelter Island, Middletown, Johnstown, Gloversville, Ilion, Flushing and Cold Spring.

An executive session was held and a recess then taken until 3 o'clock p.m. Several amendments were made to the constitution and by-laws when they reconvened. The Committee on Apprenticeship reported that it favored individual action on the part of the various organizations on the apprenticeship question. The report was adopted. In secret session the Protection Committee reported and their report was adopted. The secretary read a report of the expenses incurred by the drafting and passage of the plumbers' bill amounting to $3715. It was decided to levy a *per capita* tax of $1.78 on the members of the organization to defray this expense. The report was adopted.

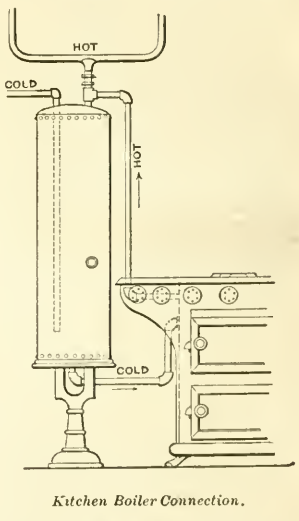
The convention concluded its business by the election of officers, Messrs. Reed, Hyde and Dwyer acting as tellers. J. A. Rossman of New York withdrew from the renomination for the presidency which was tendered him, and Charles Geiger of Buffalo, nominated by Mr. Radcliff of Brooklyn, was elected chief executive for the ensuing year.

The other officers elected were as follows: Vice-president, J. Edward James of Albany; secretary, E. L. Cooke of Buffalo; treasurer, William Ferguson of Troy; financial secretary, G. A. Smith of Brooklyn; delegates-at-large, Messrs. Vrooman of Schnectady, Viggars of Binghamton and Clatfield of Jamestown. Messrs. Rossman and McDermott were appointed a committee to institute a search for plumbing relics for exhibition at the World's Fair. The convention decided that the next annual meeting should be held at the city of Buffalo. They then adjourned *sine die*.

Ex-President Rossman took occasion to praise in the highest terms the Albany Plumbers' Examining Board. He says it is made up of good men, and that it starts about its work in an intelligent manner, using methods calculated to redound to the benefit of the trade and the public.

Kitchen Boiler Connection.

From Milwaukee Gas Stove Company, *Milwaukee, Wis.*—We have before us your answer to "C. C.," published on page 43



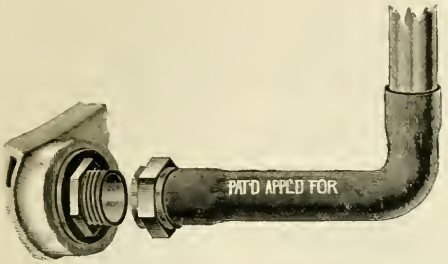
Kitchen Boiler Connection.

of *The Metal Worker* of February 25, and knowing that you are open to information and criticism we feel it our duty to set you right in this matter of boiler connections, basing our exception on actual and exact experiments. We have met with the same complaint as your correspondent in adapting gas to the work of heating water, and about three years ago hit upon the plan illustrated in the accompanying cut, being, so far as we know, the originators of this method. The experiments were made with a 40-gallon tank, first with the ordinary side and then with the top connection. Comparative tests were made for 10, 20, 30, 60 and 90 minutes, all conditions being the same for each. The temperature of the water was taken before each trial and at the end of the specified number of minutes the entire 40 gallons were drawn off into a bathtub and the mean temperature recorded. In every instance the top connection showed the better result. That we obtained a higher mean temperature was a surprise to us, and we can only account for it by the fact of the heated

area being less, and the radiation thus proportionately decreased. However, the fact remains as stated, and should these tests be doubted we respectfully advise that they be repeated by others and the result, we are sure, would be that never again, under any circumstances, would the "good (?) old way" be advocated.

Rubber Closet Connection.

The A. Y. McDonald Company, manufacturers of plumbers' supplies and sanitary specialties, 168 Lake street, Chicago, are putting on the market Morrison's



Rubber Closet Connection.—Fig. 1.—*General View.*

rubber closet connection. The device, as shown in Fig. 1, is designed to slip over the closet coupling, also the supply pipe. Being made of rubber, and accordingly flexible, all danger of cracking or breaking of closet caused by a rigid pipe is avoided. The fixture is made for $1\frac{1}{4}$-inch pipe, and is 8 inches in length. In

Fig. 2.—*Sectional View.*

Fig. 2 is presented a sectional view which clearly indicates the manner in which the device slips over the closet coupling.

A Vent Pipe Question.

From P. S. J., *Cambridgeport, Mass.*—I was recently asked to estimate for the plumbing work of a factory four stories in hight, all of the fixtures being on the first floor and consisting of two automatic long range closets for male and female employees, two sinks for same and a water closet and wash basin for the use of the clerks in office. I figured on a 3-inch vent pipe being necessary as well as a line of 5-inch soil pipe, there being no plumbing plans prepared. Another plumber figured on the job with one 5-inch line of pipe and without the 3-inch vent pipe and got the contract. Does the omission of the vent pipe line under the circumstances constitute a job executed "in accordance with established sanitary requirements," as set forth in the conditions?

Answer.—The successful plumber was evidently more "wide-awake" than our correspondent and seemed to have understood the situation more thoroughly. We have no other particulars than what are given above, but it is not difficult to perceive how the work could be done with only one vertical line of 5-inch pipe and yet conform to all ideas of modern sanitary progress. A single line of 5-inch pipe extending through and above the roof is all that would be necessary, as all of the fixtures could discharge into it through Y branches at or below the first floor, while the several traps could be vented into it in the usual manner. There would be no danger of syphonage with a 5-inch line of vent pipe with no fixtures above the lower floor. If there were fixtures called for on any of the upper floors the vent pipe should be used, but when there is but one group on one floor only the second line of pipe would be superfluous.

Modifications of New York Plumbing Regulations.

The outline for a plumbing system, which would be entirely satisfactory and meet the demands of modern sanitary practice, which we published recently in connection with the plumbing of a New York City house, has evoked a considerable amount of inquiry as to whether the system, as sketched, was intended as an ideal one, or if it actually represents the work in every detail, as executed at the present time in New York.

In reply, we desire to state that the article embodied nothing that was not called for in the regulations of the Health Department, in force for many years. These regulations are always subject to modifications, and it is but proper that we draw attention to some changes made within recent date, by which the mandatory character of certain features of the work has been removed and the option of the builder or owner substituted.

The modifications to which we allude affect only the vertical lines of pipe which extend above the roof. For some years past it was required by the health regulations that the diameters of the extension should be increased in the small bore pipes (2-inch and 3-inch) to 4 inches above roof, while the 4-inch and 5-inch should be enlarged to 5 inches and 6 inches respectively. This rule has been modified in so far that while the minimum diameter of the pipe above the roof is fixed at 4 inches there is no need of enlargement where the pipe within the building is not less than that diameter.

It was also compulsory within the period already specified to carry each line of pipe independently above the roof instead of branching the vent pipe into the soil pipe above the highest fixture, according to old custom. A modification of this plan is permitted now and it is no longer a requirement of the plumbing code. A return to the old plan is permitted, and, where a few years ago two pipes were extended, only one pipe now opens above the roof.

One other feature of the vertical vent pipe deserves some comment. By reference to the diagram, published in *The Metal Worker* of February 25, it will be seen that the pipe, instead of starting from above the trap of the lowest fixture, is carried below and connected by means of a Y branch into the soil pipe. The adoption of this method was due to the fact that the foreman of a prominent master plumber of this city (John Byrns of Grand street) in setting up his lines of pipe made this connection, which appeared to the inspector to be so marked an improvement that on his report it was adopted as a feature of the plumbing regulations.

The Weight of Mercury, and Other Questions.

The following letter was received from an apprentice in New York City, or rather what we call nowadays a boy or helper. It is the sort of letter that we like to get, not that the particular question involved is of such great interest, but because it shows that the boys and younger members of the craft are keeping their eyes open and endeavor to learn all about their trade. It furthermore shows that they are growing critical, and when they see a statement they want to have it proved. This spirit is a promising one for the trade at large. We shall be glad to do what we can to assist these younger members by answering questions or promoting discussions for their benefit. The letter from our correspondent reads as follows:

In the article on the plumbing of a house in *The Metal Worker* of February 21, you say that every inch of mercury is equal to $\frac{1}{2}$-pound pressure to the square inch. My boss says you are way off and that an inch of mercury is more than that. The foreman says you are right and is willing to bet on it. They both think they are right, but cannot prove to us boys whether they are or not. As we can't find out from them, it would be a good thing to settle the matter. The Board of Health inspector makes us bring the mercury up to 10 inches, and he says that is 5 pounds to the square inch. We don't often get a chance to read up on plumbing work, and if you would ask your subscribers to let the boys have a show at the paper it would help us.

The statement that we made in *The Metal Worker* about the weight of mercury is practically correct and we think it is the "boss" who is "way off" in saying that the mercury weighs more than $\frac{1}{2}$ pound to the inch. As a matter of fact the inch in the gauge shows a fraction less than $\frac{1}{2}$ pound pressure, or to put it exactly, 0.491 pound. As the difference between this and $\frac{1}{2}$ pound, however, is only about $\frac{1}{8}$ ounce, we think it is perfectly proper to speak of an inch of mercury as weighing $\frac{1}{2}$ pound.

What our correspondent says in conclusion about the advantage to be derived by reading trade papers is the strongest sort of testimony that can be offered in favor of this class of publication. The fact that the boys do not have the opportunity to read them is to be deplored and we earnestly second the suggestion that our subscribers give their boys a chance to see the papers. However, we fear, in many, if not the majority of cases, it is not the employers' fault, for it often is the case that when the boys are given every opportunity to improve themselves by means of papers and books they do not care to avail themselves of the chance. A curious illustration of this was a letter we received not long ago from an employer in the West who was interested in sheet-metal work and took

every occasion to let the apprentices in his shop read and study in their trade. He went so far as to subscribe for *The Metal Worker* especially for the boys, so that they could each have a copy. As long as the novelty lasted the boys were interested in their papers, but the employer found to his sorrow that in a very little while they were all left unopened and he came to the conclusion that the experiment was a failure. The letter above referred to and the letter printed herewith from the correspondent represent the two extremes. It is our firm belief, however, that each year the younger members in all the mechanical trades are more and more realizing the value of education in their calling and are taking every opportunity to improve themselves. We believe that a special paper in their line is of very great assistance, as it keeps up with the current matters, gives instruction in primary work and at the same time contains articles of a more advanced character to interest those who are nearer the top of their trade. It is sometimes impossible to persuade old or middle-aged men to read and study, but where a young man shows a liking for acquiring information, the chances are all in favor of this liking lasting all through his life.

Cellar Surface Drainage.

From G. F. R., *New York.*—Your article on "Plumbing for a City House" in *The Metal Worker* of February 25 covers every point except as to the carrying off of surface water from the cellar floor and on this point I desire information. It frequently occurs that a natural spring is in the cellar of a carefully built house, which, in a greater or less degree, tends to impair its healthfulness. The difficulty is to drain it into the house drain without the danger of allowing the entrance of sewer gas. The Board of Health requirements allowed a drain pipe to be run under the surface of the cellar floor, provided it had a running trap below the perforated grating in the floor, and that between the trap and the point where the drain enters the house drain there should be placed a "cut-off valve" as a protection against sewer gas in the event of the trap seal being destroyed by evaporation. The "cut-off valve" intended by the Health Board was either the gate or the globe valve, either of which I should say is not suitable. Will *The Metal Worker* suggest some practical ideas in cellar surface drainage?

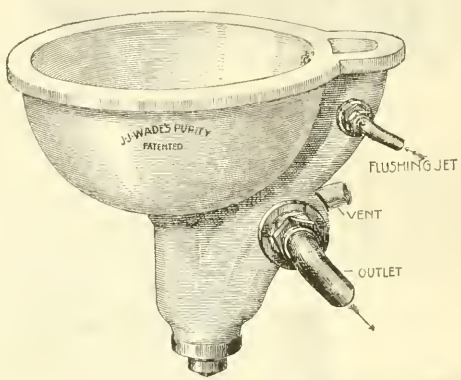
Answer.—The requirements of the Board of Health prior to June 1, 1892, and we presume of the Building Department since that date, call for such a valve as our correspondent refers to, but the question is, How will it work? Water which accumulates on a cellar floor is never free from dust and gritty substances, and these cannot get through a gate valve without depositing some of the aforesaid gritty matter in the valve. This naturally prevents the closing of the valve against the inflow of sewer gas, and it is therefore of no use whatever as a cut-off valve. The globe valve is open to the same objection; so that where surface cellar drainage becomes necessary the main point is to devise a plan by which the subsoil drain trap will be kept water sealed, and at the same time protected against the backing up of sewage on the cellar floor, in the event of the house drain becoming obstructed. The following plan has been tried in this city, and found to answer every requirement: A 2-inch drain pipe is laid from a depressed point in the floor and carried under the floor surface to a 2-inch Y branch opening set in the house drain at its lowest point on inlet side of front wall trap. The opening to this drain should be a small sink set in the floor, the flanged sides flush with the concrete surface. Under this sink a 2-inch running trap should be placed, and between such trap and the 2-inch Y-branch opening in the house drain a flap valve (or tide-water valve) should be set. Into this floor sink the safe wastes from fixtures in house and overflow pipe from house tank should empty, while the sink should be water supplied and the water pipe furnished with a draw cock. This arrangement would work as follows: The surface water from cellar floor, charged with its usual supply of ashes, dirt, &c., would flow into the depressed floor sink, the grating of which would prevent the dirt being carried into the pipe. Whatever discharge would come from the safe wastes would enter in the same manner. Both sink and drain pipe could be readily flushed by means of the draw cock, and the running trap underneath should consequently always have an abundant water seal.

The flap valve set on the 2-inch drain between the trap and the main house-drain opening would effectually prevent any house sewage from backing up on cellar floor in the event of house-drain obstruction. In this manner the surface water can be carried away without any trouble, the trap under the floor kept water sealed and all danger from the backing up of sewage from the house drain averted.

To accomplish this result, however, the main house-drain trap should be a sufficient depth below the cellar floor to enable the 2-inch subsoil drain to be set at the proper incline to carry off the surface and other water entering it through the depressed floor sink. The 2-inch drain trap should also be provided with handhole cover and a manhole constructed in the floor above the trap and the flap valve to make either or both accessible should they require attention. This arrangement would cover every requirement, and with proper attention the cellar would be both clean and healthy.

Wade's Combined Washbowl and Trap.

J. J. Wade of Chicago, has invented a wash-bowl and trap combination which has many ingenious and practical features. An illustration of it is herewith given. The basin is manufactured in commercial sizes—round or oval. The trap is molded on the bowl and is the usual S form. The overflow leads down dipped into the seal of the trap and thus completely emerges in a large body of fresh water the house side, the overflow itself, and the sewer side of the trap. Since by this arrangement the water in the trap is brought close to the bottom of the bowl, there is no space left for the gathering of filth. The fixture is made of the finest quality of porcelain, its interior being as finely and as smoothly glazed as its exterior, and thus a safeguard is placed against the possibility of a collection of filth on the sides of pipes. The overflow opens with an enlargement even with the top of bowl, in order that a soap or toilet cup and strainer may be attached and the drippings find a direct outlet. This precaution guards against disorder and the accumulation of suds and dirt on the slab. A flushing jet is placed near the crown of overflow, by means of which a live jet pressure of water may be introduced, thus flushing the interior of the overflow and the waste pipe attachments when desired. This flushing jet is so constructed that it penetrates into the bottom and sides of overflow and trap, thus leaving them thoroughly flushed and clean at all times and preventing the settling of foul matter.



Wade's Combined Washbowl and Trap.

This fixture is an especially desirable sanitary appliance for bedrooms, since it is distinctively an anti-sewer gas appliance. The brass connections are so constructed that they may be reversed to suit position when joined to waste or vent pipes, so that one may be used for waste pipe and the other for the vent pipe, or *vice versa*, as the plumber may desire. The couplings are bent or straight to meet any requirement. The fixture is claimed by the inventor to be the most simple, the easiest connected, the cleanest bowl that has ever been introduced.

Mr. Wade has won prominence in the invention of sanitary appliances of recognized merit, and has perhaps done as much as, if not more than, any other single individual in the country to bring about reforms in sanitary work. His specialties are supplied to the trade through J. J. Wade & Son, 298 Dearborn street, Chicago.

Plumbing in New Jersey.

We extract the following remarks from the lately issued annual report of the Bureau of Labor Statistics of New Jersey. Dealing with the question of health and trade life of workmen in various industries, it is said, as regards the plumber of New Jersey:

A plumber is rarely found who has worked at the trade for 30 years. They generally become rheumatic and stiff, or too feeble to do a full day's work. They must be in full vigor, and after becoming stiff in their joints they are obliged to quit the trade.

The plumbing shops are all rather untidy, but there is nothing in them in the matter of material that is dangerous to health. The only serious cause of complaint is in repairing old work. Very much of the work of plumbers consists in repairing what has been imperfectly done, and has given out much sooner than would have been the case had it been honestly finished in the first place. In repairing, there are more or less bad odors from which the workmen are liable to get sick. The water closets, privies and waste pipes that have been poorly constructed are very bad in this respect. Nearly all the work is inclosed in the walls of houses, and many people wait until the smells become unendurable, and often until some disease, like malaria, typhoid or diphtheria, attacks some member of the family before calling in the service of the plumber. The larger part of house building is let out by contract to the lowest bidder, and the sharp competition of contractors causes them to engage to do work for a price below which it can be honestly and properly performed. The result is that in a few months or years it has to be done over again, after having caused sickness or endangered the lives of those who are subjected to its effects.

In my judgment, there should be a law compelling the use of the most perfect traps, and establishing an inspectorship of plumbing, with authority to condemn all work not up to a standard necessary to the protection of health. I am sure, from my experience, that if this suggestion were adopted it would prove advantageous to both house owners and honest employing plumbers. It would protect the former from being swindled and the latter from the competition of those who take a job for too low a price and depend for their profits upon slighting the work. It would also have the effect to raise the standard of work required and cause an advance in wages.

The practice of contract work, and especially of subletting it, has a tendency to lower the quality of the work, and is a disadvantage to the trade in general, while in the end there is no saving to those who pay for it. The contractor expects a profit, and he secures it by slighting the work, so what is saved in the original cost is more than counterbalanced by repairing and patching that has to be done in a short time.

Return and Flow Pipes.

From L. V. C., *Albany, N. Y.*—I wish to know what rhyme or reason there is in calling the hot-water pipe pipe between range boiler and water back the return pipe. To do it is directly contrary to ordinary practice in the heating trade. The hot-water pipe leading from the water back to the boiler is, whatever you may call it, the flow pipe and the lower or colder pipe is the return pipe. The water back is the boiler, properly speaking, and the water is brought back to it through a "return" pipe.

Answer.—As a general thing, custom and precedent are responsible for much that may not be strictly correct in nomenclature, and in this way we might answer our correspondent's inquiry. But his communication does not convey any convincing proof that he is correct in the erms he applies to the pipes leading from the range boiler to the water back and return. He presents merely the views entertained by the heating trade and it is a fit subject of inquiry whether the plumbing or heating trade adopt the better term for the pipes in question. Let us consider the matter impartially. The plumber presumably maintains that the terms he uses are correct in their application. The object to be accomplished in the setting up of the kitchen boiler, the supply of water and the connection with the water back is to provide a hot-water service through the house. To do this we must first provide the body of cold water and the receptacle in which to hold it; next, to convert the cold water into hot water. In pursuance of recognized plans we have to create a passage for the transmission of the cold water to the water back to be heated and then returned to the boiler in the condition which was needed. The water back is not the receptacle where the body of water preparatory to its undergoing the change of temperature is stored. The boiler is that receptacle, and consequently the water which passes in given quantities into the water back in order to be heated must be returned to the boiler when that result is accomplished. The boiler is not supplied with water from the water back; on the contrary, the latter is simply utilized to produce the necessary change in the temperature, and when that is effected it is "returned" to the boiler by means of what seems to be properly designated the hot-water "return" pipe. If the word "flow pipe" is to be substituted for either of the pipes, it seems as though it should apply to the lower or cold-water supply pipe, because the water flows through it to the water back and is thence returned through the higher pipe to the proper receptacle. We agree with our correspondent that the water back is, properly speaking, the boiler, but we do not agree with him when he states that the water is brought back to it through a "return pipe," for the reasons above stated.

Noise in a Range Boiler.

From R. J., *Pulaski, Va.*—Some time ago I connected a boiler to the water back of a range. At times it makes a thumping noise, but more so when the fire is first started. Please explain to me how to remedy this.

Answer.—The trouble with this job is probably caused by defective circulation. To just what particular defect the fault may be ascribed we are unable to state, owing to the rather limited description sent us. The following are some of the principal causes to which such a trouble may be traced. It may be that the pipes between the water back and boiler are not of sufficient capacity to allow a free circulation. Then the pipes, even if of the proper size, may have become partially filled and obstructed with sediment and scale. The same cause may be present in the water back. If the heated water cannot circulate and flow from the water back to the boiler as fast as it becomes heated, it will become too hot and be converted into steam, and the sudden condensation of this steam by cold water will give rise to the noises complained of. In some cases the cause may be traced to faulty workmanship, such as almost solid wiped joints, traps in the arrangement of the piping, &c. Then the internal cold water pipe in the boiler may not be of the proper length. It should extend down some distance below the point where the hot-water from the water back enters the boiler. Finally, the supply of water to the whole system must be ample and of sufficient pressure to meet all demands that may be made on it.

TRAPS AND VENTS.

THE W. S. EDWARDS MFG. COMPANY, makers of fine gas and electric light fixtures, 86-88 West Lake street, Chicago, have secured more central and commodious quarters in the five-story and basement building at 21 East Lake street. They have removed the offices to the new location, and will in a short time have their factory in operation there. The machinery will be driven by electric power.

THE ANNUAL MEETING of the Haydenville Mfg. Company was held at the office of the company, Haydenville, Mass., February 25. The old Board of Directors were re-elected, viz., Arad T. Foster, Henry F. Peck, John M. Peck, Homan H. Beals and Cuyler K. Sanborn. They report having had a good year's business, with an increased production of $60,000 at the Haydenville mill over the preceding year. They have recently put in some new and improved machinery and 50 additional hands to the force already employed. The mill is in charge of C. B. Hosford.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until 2 o'clock p. m., March 23, 1893, for all labor and materials required for plumbing and gas piping for the United States Court-House, Post-Office and Custom-House Building at Bay City, Mich.

HUGH WATT, plumber and gas fitter, 300 Dearborn street, Chicago, has secured the plumbing contract for the woman's dormitory at the World's Fair, also for the 84 Gerald flats at Twenty-sixth and State streets.

S. DAVIDSON, 56 Beekman street, New York, selling agent of the Steel Bath Mfg. Company, Detroit, Mich., is much pleased with the results of the "missionary work" to which his attention has been given since establishing himself in this city last November. His efforts have been among architects, builders, jobbers and others having to do with the selection of bathtubs. These tubs are put in competition with higher-priced goods of earthenware or iron, only obtainable by the rich. They can be sold at a moderate price and many advantages are claimed for them. They weigh but 95 to 100 pounds, an item not to be ignored when considering the weight on floors and expense in handling. The tubs are supported by ornamental iron feet, gold bronzed. They are detached and every part readily got at, there being no casing. The outside shell is of steel painted light blue, with a lining of planished copper. The wood rims are of polished cherry, oak or other ornamental wood, so attached and leaded that moisture or vermin find no lodgement. They are made in two patterns, French and Roman, in three and two sizes respectively, both being supplied in 12-ounce, 14-ounce and 16-ounce copper.

The output of pig tin of the world for the year 1891 was 57,551 tons. Of this amount 36,061 tons were produced by the tia mines of the Straits Settlements on the Malay Peninsula, while a further 12,106 tons were the output of Netherlands, India, whose tin-bearing islands are within a short distance of Malaya. This leaves but 9,384 tons for the rest of the world. It is stated that the supply of the tin mines on the Malay Peninsula is practically inexhaustible.

Lining Tanks with Copper.

A correspondent in Norwich, Conn., sends us this inquiry: Please inform me through *The Metal Worker* how to line tanks with copper? How are they wiped, and what is the process of wiping seams on copper? The author of the series of articles on coppersmithing, John Fuller, Sr., to whom we submitted these questions, has furnished us the following reply:

Our correspondent's question is a little vague and indefinite, seeing tanks are constructed of various kinds of wood, slate or other stone and brick work, and yet it may be desirable to have them lined with copper. It will be readily seen, therefore, that the lining would have to conform to an inch wide on both sides and at the two ends for soldering. When washed clean they are seamed together similar to continuous roofing and made the length required. Now examine Fig. 1 and suppose the sheet A B C D shown there to represent the lining of the tank. Find the middle, N K. Now mark off with a slate pencil or a chalk line the end F G, making it from F to G 2 feet 11¾ inches; then the two sides E F and H G, making them 3 feet 11¾ inches, thus allowing ½ inch for the thickness of the sheet and the turn of the corner, which cannot be turned sharp enough to go quite close up into the corner. Mark off the two halves of the other end, A E and C H, each one-half of F G, and leave on enough for the seam; then notch the side you intend for the bottom, as at B and D, and fold the ends ready for the seam. Next strike the line M O, making while the work of making the seam is going on. When completed make the return here to correspond with the other end and two sides, and knock the corners smooth and a little round so they will not catch in the angle of the wooden side as you slide it down into its place. Put the sides into the tank, and when it is down in its place and properly fitted, nail through the under lap at the corners with copper nails if at hand; if not, with the next most suitable for the purpose.

Now to prepare the bottom. If you wish to seam it in, turn up an edge on the return about ¾ inch deep with a pair of roofing tongs and then a similar edge on the bottom ½ inch wide and make it fit snug in and up to the edge of the return edge. Examine the work now closely, and if the bottom fits suitably to proceed turn the return edge (which is ¼ inch wide) down

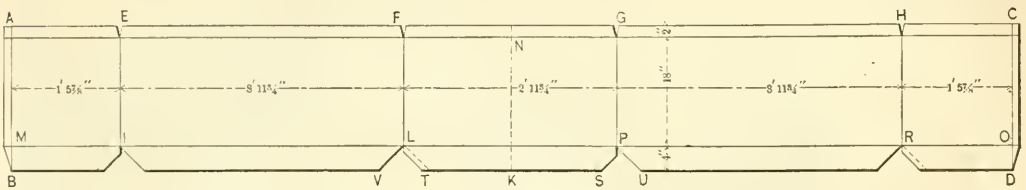


Fig. 1.—Pattern for Lining Prepared by First Method.

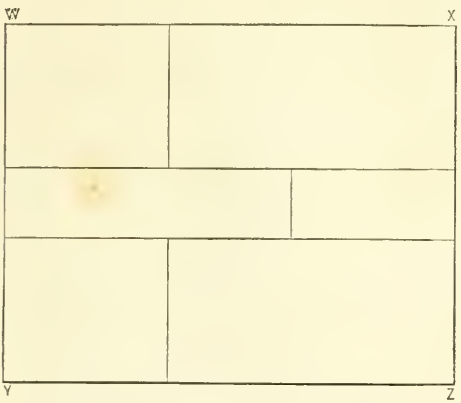

Fig. 2.—Showing Way Sheets Lie Together.

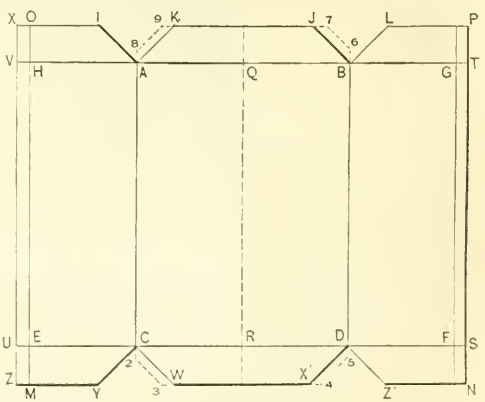

Fig. 3.—Pattern for Lining Prepared by Second Method.

LINING TANKS WITH COPPER.

circumstances and would require good judgment to be used. We will take it for granted, however, that in the case before us the inquiry means the lining of wood cisterns. Here again we must assume that the lining is to be of light copper sheathing similar to sheet zinc, and we must suppose some size (as none is given). Let it be required, then, to line a cistern or tank 1 foot 6 inches deep, 3 feet wide and 4 feet long, inside measure, and let the wood backing be ordinary 2-inch plank.

FIRST METHOD.

Copper sheets such as I have been in the habit of using measured 24 inches wide by 48 inches long, and so we have two ways open to us by which we may execute the work required. In Fig. 1 is illustrated the pattern of the lining prepared for the sides in the first method. In Fig. 1 the sheets have been first squared up and cut the necessary width, which in this case means only trimming, and the edges of the sheet tinned about the distance O D and M B 4⅛ inches. Take a level set at an angle of 45° and lay it on the line M O at the points L and P and mark the lines P U, P S, L V, L T, leaving on the sides S P and L T, say, 1¼ inches for under lap at the corners, and the same at I and R. Clean and tin the return or bottom edge, both sides, with a suitable soldering copper, and when cool enough wash off the acid used with a wet wisp and clean water, and then dry it. Now, if a suitable pair of roofing tongs are at hand, lay the metal on the floor and with the tongs turn up the return for the two sides and the middle end. If you have no tongs, lay of piece of studding or any suitable piece of timber at hand on it at the line, and pull sides and end up square and dress them true with a mallet. Bend the corners square, lock the seam and knock it down close; then solder it down within 2 inches of the bottom edge, keeping the sides in shape with two crosses (×) made of 6 inch board nailed together in such a way as to hold the sides in shape over the edge of the bottom similar to the standing seam of a roof and close the edge smooth all round and notch the corners. Now take a hatchet stake and lay the blade flat on the bottom, and with a mallet bring the seam over on the blade all round, after which the seam may be closed down on the bottom and smoothed for soldering. The soldering may be done with the ordinary tinner's soldering coppers of sufficient capacity. If it is not desirable to seam the bottom in, then nail the return edge at suitable intervals so that there be no buckle, and lay the bottom in place, nailing between the under nails and letting the bottom lap, say, 1 inch all round. This also may be soldered in the ordinary way.

SECOND METHOD.

In Figs. 2 and 3 is illustrated a second method of preparing the sheets, in which the lining is finished at the two ends of the tank. Examine Fig. 2 and notice the way the sheets lie together. I have allowed

nothing for seams. W X Z Y is the same size as M N P O in Fig. 3. Now having all the sheets seamed together and made the size required, as in M N P O, Fig. 3, we will line out the pattern and proceed as follows: First square the metal, and draw the center line Q R, and from Q and R measure off each way Q A and Q B, 1 foot 5 ¾ inches, thus deducting ½ inch each side for the thickness of the sheet and the turn of the corner, and making the distance, A B and C D 2 feet 11¼ inches. Now mark off H A and B G, and E C and D F, making them 17⅞ inches, and from F S and G T 2 inches, and at E U and H V 2 inches. From M and N mark off 6 inches, N S and M E, on N T and M H, and draw the line E S. From O and P mark off 6 inches, P T and O H, on P S and O E, and draw the line T H. Then take a bevel set at an angle of 45° and lay it on the line E S at the points C and D, and mark the lines Y C, and C W, and X' D, D Z', leaving on C W and D X' about 1¼ inches, as shown by the dotted lines 2 3 and 4 5 for under lap at the corners (for soldering). Next line off the corners I A K, J B L, at the other end O P the same way, and cut out with the hand shears the gusset pieces Y 23, Z' 54, I 89 and L 67. We are now ready to form up the sheet, which may be done in a similar way as before directed, and the ends seamed in the same manner as described for the bottom in the first method, the tank being turned on its side, and soldered with soldering coppers in the usual way.

In the foregoing I have supposed the work was to be done in the shop, where the tanks could be manipulated as required to suit the work. But we will now suppose the cistern to be a fixture. If there be room adjacent to the cistern, prepare the metal on the floor in a similar way as before described; if there is no room, then proceed as circumstances dictate, using the best judgment to save time and labor. When the lining is all in proceed to solder the upright seams as follows: Take some good soldering acid, and with a brush apply the acid to the joint to be soldered. Be particular and have your soldering copper nice and clean by frequently dipping the point in a jar of sal-ammoniac and water, and have the nose nicely tinned on all four sides. Now with a stick of good fine solder begin at the bottom, placing the solder against the seam, and with the copper bite off a drop of solder, which will hang to the soldering bit and transfer it to the seam; then bite off another drop of solder and carry it to the seam in the same way just above the other, and proceed in this way little by little until you get to the top, doing an ½ to a ¼-inch at the time until by practice you can do better. The perfection in soldering upright seams can only be acquired by patience and practice. The ability to do this kind of soldering work lies in being able to carry the solder from the stick to the seam in such a manner that it will look like Fig. 4 when finished, which can soon be attained by the proper effort and perseverance. When all the upright seams are done proceed with the bottom. Take time now and see that the seam is soldered strong, and examine closely to see that every part of the joint has been tinned properly and covered with solder. When the joint is finished, always wash it off with a clean wisp and clean water, then dry it.

WIPING SEAMS.

Wiping seams requires practice. If our correspondent has had no practice and never saw this work performed, perhaps he had better not attempt it until he has, at least outside of his own shop, where he may make the attempt until proficiency is attained. But I will do as much as I can in this brief article to assist him with a few hints as a guide to the wiping of joints of this kind. If then the tank be a fixture and large, say 18 inches deep, as in the first case, the side and bottom of the tank must be grooved or channeled out where the seams come, say about ½ inch deep and 1½ inches wide. Now look at Fig. 5. First lay the bottom, and let the channel be at least 6 inches from the side (never get the seams in a corner closer than 6 inches if you can avoid it), and contrive, if you can, to get the upright seams where they can be got at easily. Lay one edge of the seam right over the channel and sink it in and tack it at the two ends and in the middle, and then lay the edge of the next sheet in the middle of the channel and tack it to its place with copper tacks, as in K and M. N O shows a section of the bottom and K and M shows how the bottom and sides come together; B E F D shows the bottom seam, and H G a side seam.

We will assume the above instruction is sufficient, and we have the lining all in and ready for soldering. It is of course supposed that there have been two persons at this work, one, the tinner or coppersmith, and the other a helper. The main thing in our next step is to get ready for wiping the joints. To do this we want a few things which I will enumerate: The first thing is a splash stick. This may be made of wood or sheet iron and about 7 inches long and 1½ inches wide; and if of wood, about ¼ inch thick. Next a cloth. Some men use good stout bed ticking, others good fustian or moleskin cloth. I have done good work with ticking, and it is easier to be had. Take a piece of good ticking, about 9 x 12 inches, and fold it up 4 inches one side, then again 4 inches, then double it again, making it 4 x 4½ inches, and six thicknesses thick; then sew up the ends to keep it compact. Now melt a little tallow until it is just liquid, and soak the cloth in it on one side, and it is ready for use. The tallow (or touch) is to prevent the solder from sticking to the cloth; it is best to use one side of the cloth and keep it smooth. Next we want a solder pot and ladle; both of a suitable size for the job in hand; and last, two or three plumbers' irons, Fig. 6. If none are at hand the work may be done by using in their place soldering coppers of a suitable size. We also need a fire pot Besides these tools, have also handy a little powdered rosin and a little tallow. Now lay a piece

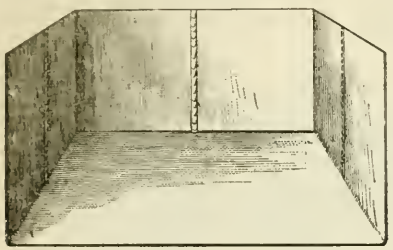

Fig. 4.—Showing Soldered Seams.

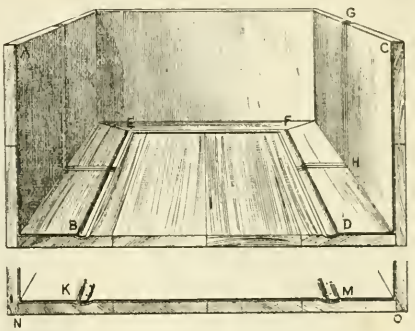

Fig. 5.—Tank Lined for Wiping.

Fig. 7.—Wiping Card.

Fig. 6.—A Plumber's Iron.

LINING TANKS WITH COPPER.

of board at the bottom of the upright seam at H, Fig. 5, to catch the solder, and have another to stand the metal pot on, and see that you have enough solder. Having now a good fire, the irons hot, and the cloth warm, also the splash stick, we are ready for the metal. Take a ladle full of solder in your left hand and with the splash stick in your right begin at the top, splashing the solder down the seam, and keep at this until you have on enough, testing the condition of the solder and bringing it up occasionally off the board, still splashing until you feel it work like soft putty. When you have enough on put the ladle quickly into the pot, and let the helper hand you an iron by the tail end, and you catch hold of it with a piece of cloth or felt in your left hand; and, taking a warm cloth in your right, with the ball of the iron touch over the solder some 5 or 6 inches until it is about running, and then with the cloth lightly wipe the top smooth. Now warm the solder up again with the iron and wipe another 6 inches, and so on down the seam. Do not try to wipe if the metal is not soft and will move easily, for it will be too cold, and you may break the seam, although too fine for you to see, and the result will be a leaky joint; keep the metal well alive with the iron at the end of every spell. When you have completed the seam and before the bottom portion has had time to set, soften the solder at the bottom with an iron and clear away all surplus metal and remove the board and finish out to the channel of the bottom seam. When all the side seams are completed proceed with the bottom one. If it is preferred, the bottom seam may be made without the aid of the cloth thus: Prepare a card of thin wood, about the size of the cloth, $\frac{1}{4}$ inch thick on the front edge and about $\frac{3}{8}$ inch at the back, as in Fig. 7. When ready again pour enough metal into the channel, having it well alive, and then strike the overplus of solder level with the card, keeping the card greased with tallow. Continue on through the job, being careful not to upset or break the joint as you proceed along with each spell.

With careful attention and study of the foregoing instructions, and a little patient endeavor, I hope our correspondent will be able to handle the lining of tanks with sheet copper, placing the seams and wiping them where most convenient, and soldering them by that method good judgment dictates as the best under the circumstances.

A Pretty Kettle of Fish.

Looking over our Eastern exchange we observe a statement of the achievements of the Gloucester fishing fleet during the past year, indicating that a period of unusual prosperity has been enjoyed. The following shows the number of cod that have been ensnared by the seductive hook and net, three consecutive seasons being compared:

	1890.	1891.	1892.
Western Bank	1,294,000	622,000	1,481,000
Grand Bank	18,712,000	20,475,000	24,544,000
Banquereau	330,000	107,000	2,400,000
Flemish Cape	695,000	1,280,000	562,000
Cape Shore	2,569,000	2,595,000	1,092,000
Cape North	2,058,000	671,000	2,080,000
Georges	13,481,200	10,477,788	11,980,700
Shore	1,037,195	1,841,935	1,180,706
Bay of Fundy	127,000	153,300	11,000

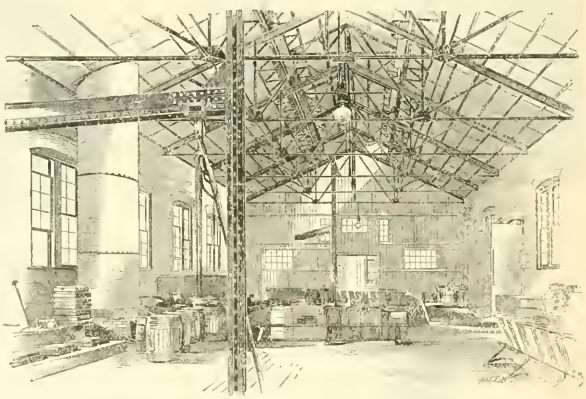
Labrador	.....	.....	105,000
Nova Scotia	.....	.....	90,000
Totals	45,568,695	43,997,123	49,749,406

Here is a record of 50,000,000 victims, not to speak of the catch of halibut, mackerel, herring, &c., which almost double the aggregate. To all who are skilled in the culinary art these figures are significant, since every individual fish before it is considered edible must be subjected to some one of the various processes of boiling, frying or baking, at once bringing into requisition all the appliances found in a first-class kitchen. Therefore the piscatory tribe sustain very close relations, in a pecuniary sense, to all who are concerned in perfecting the kitchen and of our domiciles, whether reference be had to the plumber's work, to stoves and ranges or the innumerable utensils connected therewith; and hence the propriety of giving our fisheries at least a moment's consideration in connection with the important interests represented by these various lines of manufacture.

A New Brass Foundry.

The construction of foundry buildings is receiving at the present time a great deal of attention from manufacturers. It is especially the case in brass foundries, where the cost of producing the finished metal is considerable. The accompanying illustration shows the interior of a new brass foundry just completed for Randolph & Clowes, at Waterbury, Conn., which was designed and built by the Berlin Iron Bridge Company of East Berlin, Conn. The building is 42 feet in width by 85 feet in length, the side walls being of brick and the roof being of iron covered with the Berlin Company's patent anti-condensation corrugated iron roof covering. A drop of water in a brass foundry would be fatal, and for this reason manufacturers have not been able to use corrugated iron roofs in the past, owing to the drip from the under side of the corrugated iron. The Berlin Company's patent anti-condensation corrugated iron material has met this trouble, and they are now able to produce a corrugated iron roof which they guarantee will not condense moisture on the under side, and at the same time will be fire proof. They have furnished a large number of these for electric light stations, brass foundries, &c, some having been in use for several years. The building as shown is ventilated on the ridge by one of the Berlin Company's ventilators with corrugated iron shutters on the sides, which open and close separately and independently, and thus affording ample ventilation in all kinds of wind and weather. The interior arrangements of this casting shop are only indicated in the engraving, the idea being to show more particularly the roof trusses and the general construction of the building.



THE RANDOLPH & CLOWES BRASS FOUNDRY.

A Garbage Destroyer.

A crematory for the destruction of the city's garbage has recently been erected in Boston by order of the municipal authorities, which appears to do its work most efficiently. The following extract from a local journal gives a description of the operation at the crematory, as witnessed on the day of its inauguration: The crematory is about 23 feet long, 10 feet wide and 10 feet high, and has fire brick walls a foot thick, covered with boiler steel, braced with great iron rods to keep them from being forced apart from the heat. The receptacle for the garbage has a capacity of several tons, and is fed through openings in the top with iron covers. The furnace in which the fire is started is a part of the structure, and is fed with crude petroleum conducted by means of pipes from a large tank a considerable distance away. A wood fire is first started and then the oil is turned on and, with other devices for generating inflammable gases, an intense heat is soon produced. A blower, run by a six-power steam engine, forces this fiery mass into the receptacle for the garbage, which is slowly fed in until it becomes a burning mass. After that the combustion is very rapid, the garbage disappearing almost as rapidly as it can be shoveled in. There are two chambers for its reception and there is a system of drafts by which all the smoke and gases go from one to the other, making a complete circuit of the crematory, and then what is left escaping to the air through a high chimney. In the test all kinds of stuff were fed into the furnace just as they came from the places where they were collected, tin cans, bottles, bones and similar matter being disposed of. From 25 to 30 gallons of oil, costing about three cents a gallon, were used each hour, consuming from four to five tons of offal an hour. Scarcely any ashes are made. The amount of garbage collected by the city each day is 200 tons, and it is estimated that this can all be consumed by four furnaces at a cost of about 25 cents a ton. The whole operation is remarkably free from odor and scarcely an offensive smell is noticeable as coming from the furnace.

The American Consul at Singapore suggests that a wholesale importing and exporting firm of known reputation might do a successful business among the 1,000,000 inhabitants of the Straits Settlements. The trade with the United States amounts to $12,000,000, and is altogether in the hands of English and German merchants.

Prize Competitions

$25.00.

FOR MORE THAN six months Weekly Prize Competitions ($10) have been an interesting and useful feature of the *Pharmaceutical Record*, a journal issued from this office and devoted to the interests of the drug trade. These weekly competitions have related to a variety of technical and business questions of interest to druggists, and have brought out a large amount of information of much service to the readers of that enterprising journal. In view of the success of this feature we have decided to announce a similar series of Weekly Prize Competitions on questions of interest to our readers, and invite a general participation on the part of the trade. As the object of these competitions is to obtain information which will be of practical service to our readers, and to discuss questions in which they are interested, we shall esteem it a special favor if any in the trade will suggest subjects for such competitions, which, if deemed suitable, we shall take pleasure in using.

In each competition there will be three prizes—a first prize of $12.50, a second prize of $7.50 and a third prize of $5. The prizes will be awarded for the answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Prize Competition No. 15.

SUBJECT:

Suggestions in Regard to the Sale of Athletic and Sporting Goods.

In this competition athletic and sporting goods are regarded as including Baseball, Tennis, Football and Gymnastic Goods, Fishing Tackle, Bicycles, Guns, Revolvers, &c.

The object of the competition is to draw out from the trade information or suggestions in regard to the sale of this class of goods—how it may be increased and made profitable—especially in the smaller villages and towns.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

Those discussing the subject are of course free to treat it as they think best, but the following points are suggested as deserving attention:

To what extent business in this line can be satisfactorily connected with general Hardware;
The kind of goods that can most advantageously be sold;
How the sale of these goods is to be increased;
Method of displaying in show windows or store;
What it is feasible to do in this line without carrying the goods in stock, sales being made from samples or catalogues.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

Replies are to be received not later than April 1, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 15.

The committee to whom the contributions in Prize Competition No. 1 were referred have awarded the prizes as follows:

First Prize to H. P. TOWNLEY, Terre Haute, Ind.

Second Prize to H. C. WISEMAN, Springfield, Ohio.

Third Prize to W. T. WARSOP, Fairport, N. Y.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 12. Closing March 11.
Arrangement of Pocket Cutlery.

No. 13. Closing March 18.
The Best Method of Changing a Credit into a Cash Business.

No. 14. Closing March 25.
Suggestions Regarding the Sale of Spring and Summer Goods.

No. 15. Closing April 1.
Suggestions in Regard to the Sale of Athletic and Sporting Goods.

Another subject will be announced in our next issue.

Separating Tin.

A patent has been obtained in Great Britain by T. Twynam of Chiswick, England, for a method of extracting tin from tin plate or tin sheet scrap. It is based on the fact that when the tin scrap is heated a film forms on the surface, which consists chiefly of tin in an oxidized state. This cannot be readily removed by mechanical means, but the inventor has found that when the scrap is heated along with some fusible salt, or plunged into a bath of such salt in a fused state, the film formed is in such a condition that it can be readily separated from the surface by boiling in water or by agitating by mechanical means. The salt which it is preferred to use, and which gives the best results, is chloride of calcium, but other salts may be employed, such as the chlorides of sodium, potassium, iron and magnesium. The scrap should be well covered with the salt and heated to a red heat until the film forms, and on being boiled in water the tin will fall off in a heavy insoluble powder.

The Antiquity of Some Modern Appliances.

Exploration among the ruined and buried cities of the old and new worlds, which is so marked a feature of modern scientific and historical research, is constantly bringing to light startling proofs of the fact that, in many respects, the ancients were not, by any means, as far behind us in the applied arts as has been generally and complacently assumed. Especially has this been the case in recent excavations carried out in those Eastern lands which are believed to have witnessed the dawn of civilization. Nineveh, Babylon, Troy, Memphis, city after city famed in remote times as a center of light, power or wealth, has had its exact location fixed by patient explorers, and its ruins overhauled and sifted, with splended historical results, as well as adding greatly to our knowledge of the arts and sciences as they existed in the earlier periods of the world's history. A very interesting instance of the fact that some of the most modern appliances were really anticipated thousands of years ago in Egypt, was recently established through the discoveries of W. M. Flinders Petrie. During a residence of two years in Gizeh, we learn from a contemporary, Mr. Flinders Petrie collected evidence showing that the tools used in working stone 4000 years ago were made with jeweled cutting edges, as is the modern custom. He has stated his reasons for coming to these conclusions and proves in a very satisfactory manner that the pyramid builders used solid and tubular drills, straight and circular saws, and many other supposed modern tools in erecting that greatest of buildings. He also shows that their lathe tools were set with jewels and that they did work with them that would puzzle the modern artisan. In one place he found where the lines of cutting on a granite core made by a tubular drill form a uniform depth throughout, showing that the cutting point was not worn as the work advanced. The regular taper of the core would also go to prove that the drill was set with jewels on the inside and on the outside alike, thereby facilitating its removal. In some specimens of granite he found that the drill had sunk one tenth of an inch at each revolution, the pressure necessary to accomplish this having been at least two tons. The capacity of the tools and the skill of the workmen are illustrated by the clean cut they made through soft and hard materials alike, there being no difference in the width of the groove when it passes through soft sandstone and granite hard as iron. Nothing is known concerning the material of which their tools were made, nor how the jewels were set. The diamond was very scarce at that time, therefore the only logical conclusion is that they used corundum.

A new metal, says *Iron* of London, has been discovered by Dr. Purcell Taylor. It possesses a beautiful violet color, having a brilliant appearance; is hard and crystalline, and has a high melting point. The specific gravity of the new metal is 8.2, and it is said that its cost will be high. Dr. Taylor has named the substance "farmanium."

Just now the fad in Mexico is growing coffee, for coffee raised in Mexico is proving superior in quality to that of Brazil or Java. Many Englishmen and Germans are buying coffee farms, which are now very cheap.

TIN PLATES.

American Tin-Plate Brands.

IV.

We present this week a further installment of brands, &c., adopted by makers of American tin and terne plates, which are actually being produced and placed on the market at the present time. It should be understood that the list does not include a number of private brands which are being made for various dealers who are not themselves manufacturers.

Aliquippa Tin Plate Company,

Pittsburgh, Pa., whose works are located at Aliquippa, Pa., inform us that they are now producing two brands of American terne plates and two of bright tin, in 14 x 20 and 20 x 28 sheets, IC and IX.

The roofing plates are:

1. "*Aliquippa.*"—Made from finest steel, heavily and uniformly coated by palm-oil process. All sheets are carefully assorted before boxing, wasters being taken out and sold only as "wasters." Each sheet is stamped with name and gauge, as illustrated in Fig. 1. Boxes are marked with brand name and gauge, and also with makers' name.

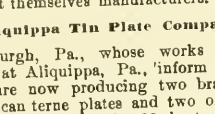


Fig. 1.—"Aliquippa" Stamp. Aliquippa Tin Plate Company.

2. "*Beaver.*"—Heavy coated palm-oil process terne plate. Sheets assorted and stamped, as in the case of "Aliquippa" plates, with name and gauge; see Fig. 2. Marks on boxes are on the same order as those previously noted.

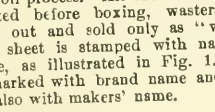

Fig. 2.—"Beaver" Stamp. Aliquippa Tin Plate Company.

Of bright tin plates are produced the following:

3. "*Aliquippa.*"—A guaranteed charcoal plate of high grade.

4. "*Beaver.*"—A coke-finish bright plate of superior quality.

Cincinnati Corrugating Company,

Piqua, Ohio, are now manufacturing two grades of American roofing plates, namely:

1. "*Piqua.*"—A heavily coated terne plate, made IC and IX, 14 x 20 and 20 x 28. Plates are not stamped. Boxes are stenciled on the lid:

MADE BY
THE CINCINNATI
CORRUGATING CO.,
PIQUA, O.

The name "PIQUA" and gauge are marked on one end of the box, and the words "PIQUA ROOFING PLATES" on the other end.

2. "*Piqua Hand Dipped.*"—A very heavily coated hand-dipped plate, to which the company are paying special attention and which comprises the great part of their output. Made in standard sizes, IC and IX. Each sheet is guaranteed perfect, squared, and stamped as shown in Fig. 3. Boxes are marked similarly to those containing "Piqua" plates, except that the words "HAND DIPPED" are added to the name.

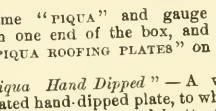

Fig. 3.—"Piqua Hand-Dipped" Stamp. Cincinnati Corrugating Company.

All the terne plates made by the Cincinnati Corrugating Company are coated by palm-oil process.

Marshall Bros. & Co.,

Philadelphia, are turning out several brands of American tin and terne plates, made from black sheets of their own rolling. Of bright plates the two following qualities are made by them:

1. "*Penn Treaty Best Charcoal.*"—Guaranteed 6 pounds of tin to the box. These plates are made IC and IX, 14 x 20, 20 x 28.

2. "*Penn Treaty Second Charcoal.*"—A lighter coated plate, 4 pounds of tin to the box, made I C and IX, 10 x 14, 12 x 12, 14 x 20 and 20 x 28. Boxes containing these plates are stenciled "A A."

Of roofing plates the concern are now putting out five qualities, as follows:

3. "*Marshall's Hand-Dipped.*"—An old style, hand-dipped plate, made by the palm-oil process. The sheets are resquared but not stamped; and special care is stated to be given to their finish and coating. Stock very carefully selected, and written guarantee is given.

4. "*Marshall Best Roofing.*"—Very heavily coated plate; coated by palm-oil process, and guaranteed. Said to be equal to "M. F." All sheets are resquared and stamped with the name "MARSHALL," as shown in Fig. 4.

Fig. 4.—"Marshall Best Roofing" Stamp. Marshall Bros. & Co.

5. "*Penn Treaty.*"—Same quality as "Marshall," but with less coating. Sheets are thoroughly and evenly coated, resquared and stamped with brand name, as illustrated in Fig. 5. These plates are claimed to be equal to "Melyn" brand.

Fig. 5.—"Penn Treaty" Stamp. Marshall Bros. & Co.

6. "*Girard.*"—A fourth grade of roofing plate, having a greater percentage of lead in the coating, and specially recommended for use where sulphur gases exist. Each sheet is stamped as in Fig. 6.

Fig. 6.—"Girard" Stamp. Marshall Bros. & Co.

Special sizes of this grade, suitable for gutters and special work, can be supplied.

7. "*M. C. B. Standard.*"—A special grade recently introduced, bearing a coating peculiar to the firm, which is recommended as a heavy coated plate, with a mixture which is guaranteed to resist sulphur gases and acids. All sheets are resquared and stamped in the manner illustrated in Fig. 7.

Fig. 7.—"M. C. B. Standard" Stamp. Marshall Bros. & Co.

All Messrs. Marshall's roofing plates are made IC and IX, 14 x 20 and 20 x 28.

The boxes for all brands of tin and terne plates are stenciled on the ends with name of brand and gauge, &c., together with makers' name.

Marshall Bros. & Co.'s trade-mark is an eagle and lion, illustrated in Fig. 8.

Fig. 8.—Trade-Mark of Marshall Bros. & Co.

Apollo Iron & Steel Company.

In the second list of tin-plate brands printed in *The Metal Worker* of February 4 it was stated, under the heading of

Fig. 9.—"Apollo Best Roofing" Stamp. Apollo Iron & Steel Company.

"APOLLO STEEL & IRON COMPANY," that their terne plates were unstamped. That firm inform us that each plate is stamped with the name of brand, as shown in Fig. 9.

SCRAP.

THE OFFICERS of the United States Iron & Tin Plate Mfg. Company, Demmler, Pa., are much pleased with the success and development of the American tin plate industry, as shown by the last report of the Government statistician, Col. Ira D. Ayer. This company is the pioneer tin-plate plant in the United States, and its officers have for 20 years worked for the establishment of the industry. The United States Iron & Tin Plate Mfg. Company issue a little pamphlet containing valuable information to the trade, which is sent free by mail to any one who will ask for a copy.

THE NEW sheet iron and tin mills now being erected by the Falcon Iron & Nail Company, Niles, Ohio, will soon be completed and ready for operation. The entire plant is being equipped with the best appliances and the mills will be modern ones throughout. The plant covers about 5 acres of ground, and the concern expect to be making sheets in their new works before this month is out and black plates for tinning purposes early in April.

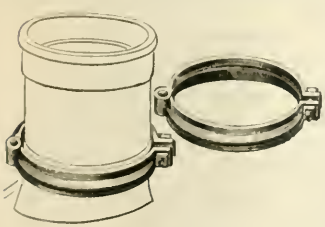
N. & G. TAYLOR COMPANY of Philadelphia, manufacturers of tin and terne plates, in addition to other goods dealt in, are now producing an average of 800 boxes a day, and a member of the firm said recently at their new distributing headquarters, 231 Water street, New York, that before the end of March they would be turning out 1000 boxes a day.

THE NEW WORKS now under erection by the New Castle Steel & Tin Plate Company of New Castle, Pa., are being pushed to completion and the concern expect to be ready for the spring trade. Their plant throughout will be equipped with the best machinery in the market, and the new firm will have every facility for the manufacture of tin and terne plates. The general manager is Geo. Greer, under whose supervision the new plant is being erected.

THE TOTAL EXPORTS of tin plates from Great Britain during the month of January last were 31,379 tons, being an increase of 2270 tons over the corresponding period of 1892. At the same time the shipments of black sheets to the United States for tinning purposes were, according to Griffith's report, of the value of $125,000 over those of January, 1892. *The Industrial World* of Swansea, Wales, says: "Tin platers are not pleased to see so much black plates leaving their shores to be coated on the other side of the Atlantic."

Berger's Pipe-Collar Clamp.

The device presented in the accompanying illustration is known as Berger's Pipe-Collar Clamp, and is intended for use in forming an air-tight joint in metal collars



Berger's Pipe-Collar Clamp.

around vent or other pipe extended above roofs of buildings. Berger Brothers of 237 Arch street, Philadelphia, Pa., who manufacture this device, state that in order to overcome the objections urged against pipe collars as ordinarily constructed, they place their hinged clamp at the top edge of the collar and draw the nut perfectly tight, after which the upper edge of the collar is calked down into the bell-shaped recess in the same manner as with other joints. In soil pipe, where stiff metal collars are used, the clamp is placed slightly above the top edge and calked with lead solder, making, it is claimed, a quick, inexpensive and perfectly air-tight joint.

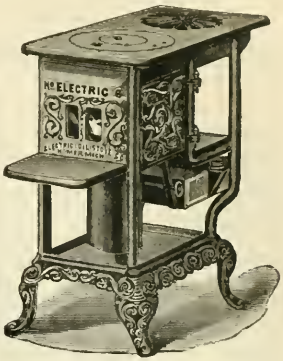
Labor in Japan.

One feature of the new civilization of Japan cannot but be regretted by those interested in the progress of that rising nation. The development of its foreign trade appears to bear very heavily upon the condition of labor, judging by a recent report of the American Board of Missions, on the work of its agents in that country. From this source we learn that the rapid growth of this trade has brought about a distressing increase in the working hours of the operatives in many of the factories where goods for export are made. Men, women, and even children, employed in the various manufacturies of silk, for instance, labor from early dawn to 10 o'clock at night, with but slight intermission. In the match factories, too, children are employed from 3 a.m. to 7 p.m. in incessant toil. And this excessive labor is not confined to the factories alone. In thousands of homes throughout Japan, we are told, the same condition prevails, especially where the industry of embroidering and hemming silk handkerchiefs for the export trade is carried on. Moreover, with all this toil, it is stated that, in many provinces, able-bodied women can earn but a pittance of 3 cents a day. A Japanese statistican places the average working hours throughout the country at 17 daily. We are not surprised, then, to learn that, in the manufscturing towns, it is rare to find operatives, either men or women, over 30 years of age. They become incapacitated for work by various nervous disorders, even if death does not intervene.

The Japanese Government is ready, it is believed, to do all that public opinion will allow them to do for the relief of these overburdened toilers. But public opinion does not yet appear to be awake in this matter, and the workers themselves have made no audible remonstrance. The Japanese is a patient toiler, with a spirit of endurance which takes everything uncomplainingly that fate may send.

The Electric Oil Stoves.

The Electric Oil Stove Company of Homer, Mich., have improved their line of oil-burning constructions for the season of 1893, embodying features which cannot fail to interest the trade. The oil range which is illustrated in Fig. 1 of the cuts is known as the Electric No. 6, and has been brought out to meet the demands for a medium-priced oil cooking stove possessing efficiency, capacity and perfect working qualities. This stove, the manufacturers claim, retains the valuable features of their No. 8 range, illustrated in these columns some time since, it being constructed on the same principle. The stove has a single 10-inch round wick burner and two griddle holes. The arrangement of parts is such that cooking and baking may be done at the same time. In connection with this and the larger size of ranges, the manufacturers offer a steel oven 12 x 13½ x 19 inches in size. It is intended to be placed over the rear griddle holes, leaving the front of the stove available for other purposes. The oil reservoir is made of galvanized iron, and is so arranged, it is claimed, that it can safely be filled while the stove is in operation, as it is separated from the flame and the oil is maintained at a low temperature, thus obviating, it is said, all danger of explosion. The end swing door affords easy access to the burner for lighting, and the burner plate can be drawn out for the purpose of cleaning and trimming wicks. The griddle, as may be seen from an in-



The Electric Oil Stoves.—Fig. 1.—Electric Oil Range No. 6.

spection of the cut, has a removable center for the purpose of heating cups, teapots, &c.

The manufacturers refer to the care and attention which have been bestowed upon the arrangement of the burners, flue, fire chambers, &c., for the purpose of giving proper ventilation and completely controlling the combustion. The company

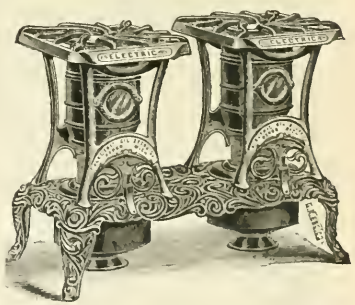


Fig. 2.—Electric Lamp Stove No. 2.

are also making a very attractive line of Electric lamp stoves, that shown in Fig. 2 of the engravings being provided with double burners. Reference is made to the improved wick raisers and rewicking attachment combined as a very simple and complete device for the purpose. The stoves are made of the very best material and are guaranteed not to leak. The oil reservoir, burner and wick raiser are entirely of brass, while the base and top castings are highly polished and nickel plated, giving to the stove a neat and attractive appearance. The No. 1 stove has a single burner, while the No. 2 which is illustrated in Fig. 2, has two burners, or what is practically the same thing, is made up of two No. 1 stoves combined in the manner shown. These lamp stoves, the manufacturers state, are invaluable to housekeepers, milliners, barbers, dressmakers, students and in fact to all who have cooking to do in a comparatively small way.

STEAM AND HOT WATER.

English Practice in Hot-Water Heating—XXII.*

COILS AND RADIATORS.

The distinction between a coil and a radiator is not at all clearly defined, unless we rely upon the fact that the former usually has its pipes fixed horizontally and the latter vertically. At the same time, if we fixed a coil on one of its ends, as is done sometimes, it would scarcely constitute it a radiator. For the information of those who have not used these latter articles it may be explained that they are, to all intents and purposes, coils, but with pipes of an ornamental character, always having the pipes fixed vertically; and, by ordinary decoration, they can be made of sufficiently good appearance to need no casing. They are also cast of such a section as to hold but little water, so that results are more rapidly obtained, but of course they just as rapidly cool as the fire goes down.

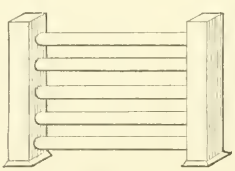
Radiators are practically the outcome of experience gained with the ordinary horizontal pipe coils. In the first place, these latter appliances are at the best of times ugly; this necessitates their being surrounded by a case, solely with the idea of hiding them, unless in an unimportant position. The case, however inexpensive, generally costs more than the coil; sometimes, when well finished, four or five times as much. Then the case goes a good way toward neutralizing the effect of the coil, as it will be understood that more heat is obtained from exposed pipes than those incased in any way. The coil case also introduces another bad feature by usually making it an impossible matter to dust and keep the pipes clean, and the horizontal pipes lend themselves to the collecting of dust more readily than vertical ones. The difference in heat diffusion between a clean pipe and one coated with dust is sufficient to surprise some people; but if it be remembered that dust is wholly composed of poor heat-conducting materials, as fiber, wool, cotton, grit (silica), &c., no wonder need be felt. Dust is almost as effective as silicate cotton in preventing the dispersion of heat.

The fact that horizontal pipes collect dust and vertical ones do not has led to the general adoption of the latter arrangement with the tubes of radiators. Horizontal coils in cases, as just mentioned, are great sufferers in this respect, and so are pipes in channels, &c., and even exposed coils and pipes are sometimes allowed to get covered with dust, and the results are lessened accordingly.

With nearly all the present radiators the necessity of a case is supposed to be obviated by their being cast of a design equal in appearance to a casing itself, and if additional finish is needed, they can be fitted with marble tops. Nearly all the makers' lists show them also made in pedestal or columnar form as well as flat, and other shapes to meet different requirements. As regards appearance, they can always be picked out in two or more colors if desired, and it has been already explained that the ordinary decorative paints and colors have no prejudicial effect upon heat diffusion. Bronze powders and gold leaf are not, however, to be recommended, except to a very limited extent.

The last point in particular to be mentioned respecting radiators is that they hold but little water. By this is meant that a certain superficial area of radiating surface has less water in it than the same area of a round pipe. It can be seen that the less water an apparatus contains the quicker it will become heated up, and it is quite possible to get the same area of radiating or heat-giving surface (capable of furnishing the required temperature) by radiators with one-half or almost one-third the water that would be held if the radiating media consisted of the ordinary 4-inch pipes. It is, however, necessary to again mention that, although the small amount of water is heated the quickest, it is also the quickest to become cool as the fire goes down. The small amount of water also shows any irregular stoking, as the degree of heat radiated is rendered irregular also; when the body of water is large these effects are not noticeable, the water acting as a reservoir or medium for the storage of heat.

With glass house works the 4 inch pipe is decidedly the best; the results are rendered as equable as it is possible to get them. The same applies to any of those places where heat is required night and day regularly. When, however, quick results for just a matter of a few hours are needed, smaller pipes are used, as, for example, a 2 inch pipe, although it has much less superficial surface than a 4 inch pipe, does not hold more than about a fourth of



English Practice in Hot-Water Heating.—Fig. 90.—Common Form of Heating Coil.

the water, and the results are quicker in proportion. Where quick results and also good appearance are needed, nothing can excel some of the forms of radiators.

The common form of coil is as Fig. 90, being a pair of cast ends, with pipes inserted as shown. The joints between the pipes and box ends are either made with yarn and lead, or more commonly, perhaps, with borings (the rust joint). A good coil can be made up by using one of the different forms of patented joints, in which an India rubber collar is the jointing material. These joints are not expensive, and the saving of time is considerable. They also have a good appearance, and are expansive (this will be referred to again). Space will not permit of giving details of all the different forms of radiators introduced; reference to the advertisement columns of this and other papers will furnish all the details required in this respect; but to illustrate the difference between the ordinary box-end coil just shown and the more modern appliances referred to, Fig. 91 will make it plain what an improvement has been made.

There are several radiators made and arranged so that fresh air can be introduced and caused to pass over the heated surfaces and so be warmed. These are generally termed ventilating radiators, but they have no particularly active effect in causing ventilation. If outlet or exhaust ventilation exists (either by ventilating flues or the ordinary fire place opening), then the inflowing fresh air will enter by way of these openings, and it will be warmed by contact with the hot surfaces.

There is one point in connection with these ventilating radiators that needs dis-

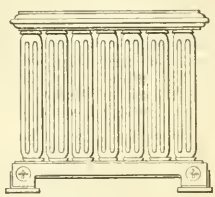


Fig. 91.—Common Form of Radiator.

cussion, which is their effect upon the moistness of the air. This subject was dealt with somewhat fully when speaking of the necessary saturation of the atmosphere in glass houses, but it may be mentioned here that when provision is made to increase the temperature of inflowing air we ought, at the same time, to provide for the increase of moisture that it needs and should have, in ratio with the heat it attains. This is provided for by some makers, who make the top castings of a trough shape to hold water, with an ornamental cover over. The temperature air attains by contact with these pipes, however, is not so great as to demand this provision of moisture in every case; the engineer must use his judgment in this respect. In hot-air works, where air is heated by contact with stoves and flue pipes, the moisture question is very important.

Among hot-water fitters there exists a considerable difference of opinion as to how coils, &c., should be connected; that is, at what point in the coil the pipes

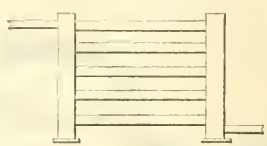

Fig. 92.—Showing One Method of Connecting Heating Coils.

should be inserted. Many seek to get one pipe at the top and one at the bottom, as Fig. 92, but there is no occasion for this; if both pipes are connected at the bottom the coil will heat just as effectively. It must not be supposed that because both pipes are at a low point the hot water will

* Reprinted from the London *Builder*.

pass in and then out without the top portion of the coil getting hot. The coil will heat just as well as one pipe at the top and one at the bottom, which is supposed to possess the advantage of causing the water to circulate right through, as it certainly does. There is one advantage this

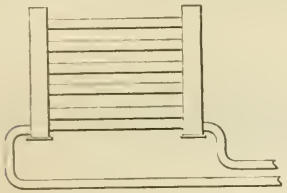

Fig. 93.—Connection Employed When a Single Coil or Radiator is on a Branch Flow and Return.

latter method has, in the fact that if the top pipe is carried from the extreme top, probably no air cock will be needed.

If a single coil or radiator is on a branch flow and return, the connection may be made as Fig. 93. It it should be one of a series on a branch service, then Fig. 94 is a good method. This latter way gives all the radiators, from the first to the last, a chance of getting hot without much interval in their times of heating. If we had, say, four radiators, and caused the water to circulate through the first one before it had any opportunity of getting to the second, and through the second before affecting the third, we should cause very irregular results indeed.

Seeing what advantage radiators have under certain conditions, it is to be expected that a hot-water pipe with full area of surface, but holding less water, will be introduced for those works needing rapid

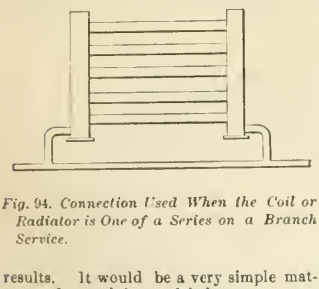

Fig. 94. Connection Used When the Coil or Radiator is One of a Series on a Branch Service.

results. It would be a very simple matter, and certainly useful in many cases where pipes have necessarily to be used, yet where heat is required at the shortest notice. It could be made of a section that would the least readily collect dust.

HEATING NOTES.

Foskett & Bishop, New Haven, Conn., issued a circular letter under date of March 1 announcing that their business in hot-water boilers was successful and satisfactory during the season of 1892. They then mention the special features of their boilers, beginning with the material. They refer to the use of steel pipe of high tensile strength and consequent safety from danger of explosion or breakage. The construction of the boiler with upright pipes, they furthermore state, promotes rapid circulation of water. The fire-box, lined with asbestos, is said to give efficient combustion. Reference is also made to the construction of the grate and the damper arrangements.

The American Boiler Company issue a tasteful advertising card entitled "Schoolhouse heating and Ventilation." The card refers to the excellent results that have attended the use of steam and hot-water systems for heating and ventilation when properly planned and erected. The further statement is made that local steam fitters are in a position to execute all contracts for this class of work which should be given them in such cases. With a view to assisting the trade in securing work of this kind, planned to give the best results, the American Boiler Company have organized the Department of Schoolhouse Heating and Ventilation, under the management of W. M. Mackay, who will furnish plans and specifications. The American Boiler Company invite the trade to advise them when such contracts are to be estimated upon in their vicinity, and they will give all the assistance in their power in enabling them to secure the work.

The Capitol Heater Company of Detroit, Mich., send us still another postal traveler, directing attention to the successful record of the Capitol heater during the past winter. They print on the back of the card a number of signed testimonial letters of very recent date.

Wanted—Good Country Roads.

When the Roman legions set out to conquer a fresh country their first care was to make a good road in their rear. And when the country was subjugated, the most important thing to be looked after by the conqueror was the establishment of a complete system of highways throughout the land so that every part of it might be accessible to the officers of the State. But they were not content with making the good roads. They saw that the condition of them was maintained. Through this means they were able to quickly plant in the conquered country—probably barbarous and rugged before—a civilization and prosperity which could never have flourished without such excellent means of intercommunication.

It is not too late in the day for us to learn a lesson in this respect from "the wisdom of the ancients." The necessity for better country roads has been brought to our minds very favorably in a pamphlet lately published by Col. Albert A. Pope, entitled "Wagon Roads as Feeders to Railways."

The book contains a collection of letters and opinions on the subject from presidents, general managers and other railroad officers in different parts of the country. As the majority of these authorities speak from personal knowledge and experience, and not from any theoretical standpoint, their opinions are entitled to careful consideration; and their aggregated opinion amounts to this: That the condition of the country roads on this continent — for Canada is represented in the list of reports — is a blot on our boasted civilization. The before-mentioned Romans were, 2000 years ago, away ahead of us in their highways.

In our Western States the average farmer, owing to the wretched roads—or want of roads—is to day unable to haul his product to market during bad weather. As that is the very time he has most leisure to do the work—which he is now obliged to do when he should be attending to his farm—the economical loss and delay caused by the want of decent roads is obvious in his one case. And this is the tale told all over the country. When bad weather arrives, country highways, as now constituted, become impassable, and railroad freights decrease enormously. Then when roads again become passable there is such a glut of merchandise at the depots as is difficult to handle, and in attempting to cope with it trains are delayed and accidents increased. Good wagon roads, which would be open for traffic, winter and summer alike, would obviate this danger and inconvenience by equalizing the amount of freight to be carried the year round, and so enable railroads to handle it safely and expeditiously. This is, of course, the main standpoint from which the matter is regarded in the pamphlet, as bearing more directly upon the interests of railroad companies. And it is an argument which affects all classes of the community.

But there are other lights in which the urgent need of better country roads may present itself to different minds. The cause of civilization, the opening up of new districts and sources of supply, the promotion of the comfort and happiness of the people, by facilities of intercommunication and consequent promotion of social relations, especially in the winter season, when under present conditions so many country dwellers, particularly in the West and South, are practically isolated for long periods by reason of the bad means of communication. All these are causes which affect the prosperity and well-being of the country in general.

Any movement which may work for the betterment of the highways of this country should therefore be most heartily indorsed, and it is to be hoped that public opinion in the matter may be sufficiently aroused to cause the inhabitants of the rural districts and sparsely settled country to awake to their true interests, and, individually, to take action to this end.

The railway companies have very generally declared their willingness to assist in the construction of good roads, by hauling the necessary material free of expense or by contributing to the work or cost in other ways. In this matter their interests are identical with those of the country settler; and if the latter would do his part, we should soon see a gratifying improvement in the country highways.

The entire establishment of the Fred. J. Meyers Mfg. Company, Covington, Ky., manufacturers of Architectural Iron Work, Wire Goods, Hardware specialties, &c., a large six-story brick structure, was completely destroyed by fire on March 5, the loss aggregating upward of $220,000, upon which insurance was carried amounting to $83,000, the greater proportion of the loss being sustained in the Architectural Iron Work department, as the material for several large Government contracts had been just completed and was ready for shipment. The fire at this time was particularly inopportune, as the company had sufficient contracts for Architectural Iron Work on hand to keep them busy the entire year and were full of orders for their specialties, to say nothing of large stock finished on hand in Wire Goods, Flour Sifters, &c. Immediate steps have been taken to secure temporary quarters for the company's different departments, and it is hoped that within a week or two they will be enabled to fill orders promptly. In the interval work will be commenced upon the ruins and new and larger buildings erected thereon as soon as possible.

The investigations undertaken by the Belgian Government into the industrial condition of the country show that in Brussels wages have risen on the average from a little over 40 cents a day in 1846 to 85 cents in 1891. At the same time the purchasing power of money has increased by nearly one-twentieth. This shows distinct improvement in the condition in that miniature kingdom.

What is said to be the largest gasholder in the world has just been completed for a gas company at East Greenwich, England. It is 300 feet in diameter, and when fully inflated is 180 feet high. The floating vessel of the holder weighs 1300 tons, and its capacity is 12,000,000 cubic feet.

THE TIN SHOP.

Templet for Elbow Miter Lines.

From J. E. B., *Troy, N. Y.*—In Fig. 1 is shown a convenient method for constructing a templet to be used in drawing the miter lines for elbows of any number of pieces. For a 90° elbow draw the right angle A B C and from B strike the arc E D C. Bisect E C and draw D B. E D then represents one-eighth of a circle. Divide E D into one less number of parts than there are to be pieces in the elbow. Thus, for a three-pieced elbow divide E D into two parts, as shown at 3'. For a four-pieced elbow divide E D into three equal parts and from E set off one of the divisions, as shown by E 4'. For a five-piece elbow divide E D into four equal parts and from E set off one of the divisions, as shown by E 5'. Other divisions can be obtained in a similar manner. Draw A F at right angles to A B and from B draw lines through the points in E D, extending them to A F. Then F B is the miter line for a three-pieced, G B for a four pieced and H B for a five-pieced elbow.

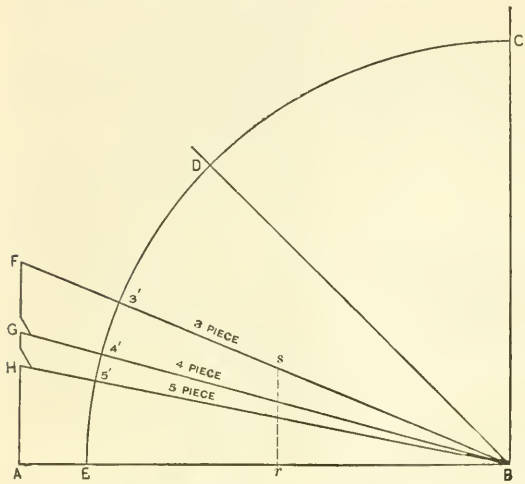

Fig. 1.—Method of Obtaining Templet.

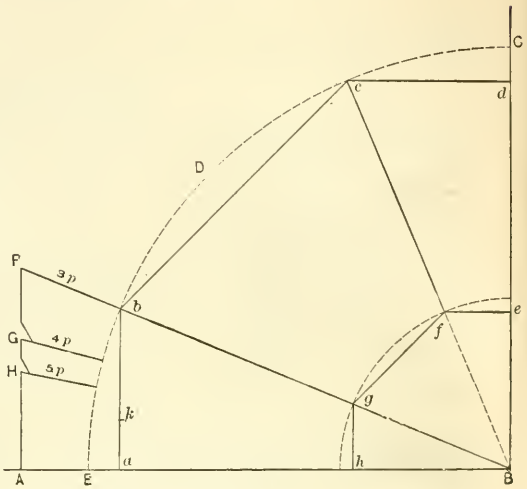

Fig. 2.—Templet Used in Obtaining Miter Line for Three-Pieced Elbow.

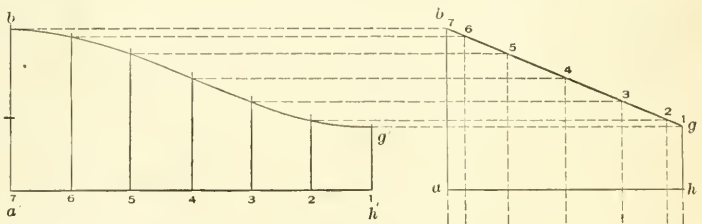

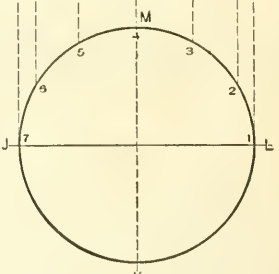

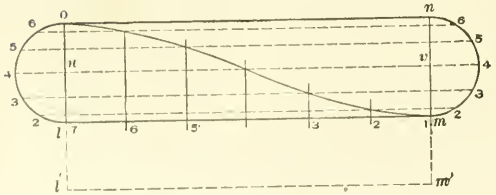

Fig. 4.—Method Suggested by "J. E. B."

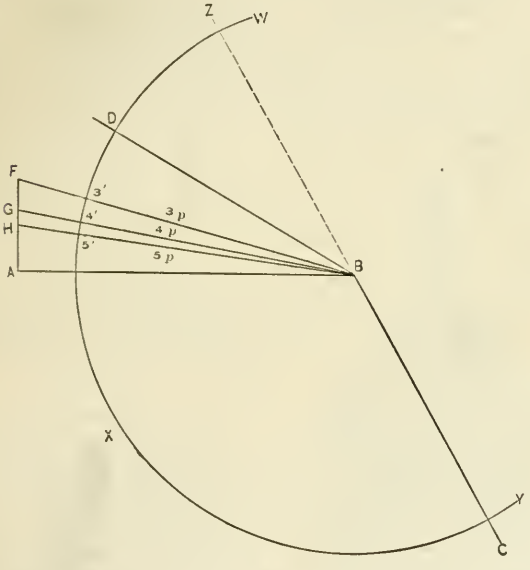
Fig. 3.—Usual Method of Obtaining Pattern of Three-Pieced Elbow.

TEMPLET FOR ELBOW MITER LINES.

The manner in which the templet A B F can be used in drawing the miter line of an elbow is shown In Fig. 2. A three-pieced elbow is represented by *a b c d e f g h*. To obtain the miter line *g b*, draw any line, as A B. From *a* set off the diameter of

elbow, as $a\ h$, and erect the perpendiculars $a\ b$, $h\ g$. The templet is then to be placed as shown, and the miter line $g\ b$ drawn. It is not necessary to draw the entire elevation of elbow as represented in the figure, as the pattern can be obtained from the miter line $b\ g$.

In Fig 3 is shown the usual method for obtaining an elbow pattern. In this figure, $a\ b\ g\ h$ is similar to the part in Fig. 2, having the same letters. In Fig. 3, J M L K represents the profile of pipe of which $a\ b\ g\ h$ is a section. Divide J M L into any convenient number of parts, and from the points thus obtained carry lines cutting the miter line $b\ g$, as shown. On $a\ h$ extended, as $a'\ h'$, lay off a stretchout of J M L, through the points in which draw the usual measuring lines. From the points in $b\ g$ draw lines parallel with $a\ h$, cutting measuring lines of similar number drawn from the stretchout line $a'\ h'$. Trace a line through the points thus obtained, as shown by $b'\ g'$. Then $a'\ b'\ g'\ h'$ is the pattern of part of elbow shown by $a\ b\ g\ h$.



Templet for Elbow Miter Lines.—Fig. 5.—Method of Obtaining Templet for Beveling Elbows.

In Fig. 4 is shown a convenient method of obtaining the whole or half pattern of elbow. In Fig. 2, $a\ b\ g\ h$, having been drawn as previously described from a on $a\ b$, set off the distance $h\ g$, or from B, in Fig. 1, set off the diameter of elbow, as shown by B r, and from r erect the perpendicular $r\ s$, cutting F B. The line $r\ s$ gives the depth of miter the same as $k\ b$ in Fig. 2. On any line, as $l\ m$, in Fig. 4, set off the half circumference of elbow, which divide into any convenient number of parts. From l and m erect perpendiculars in length equal to $k\ b$ of Fig. 2, or $r\ s$ of Fig. 1. Bisect $l\ o$ at u, and with u as center and $u\ l$ as radius, strike the arc $l\ q\ o$. Also bisect $m\ n$ at v, and with the same radius and with v as center, strike the arc $m\ p\ n$. Divide the arcs into the same number of parts as was the stretchout line $l\ m$, and from the points thus obtained, draw lines parallel with $l\ m$. From the points in the stretchout line, $l\ m$, draw the usual measuring lines, cutting lines of similar number, drawn from the arcs l, q, o and $m\ p\ n$. Trace a line through these points of intersection, as shown by $o\ m$. Any desired width can be given to the pattern, as indicated by $l\ l'\ m'\ m$. It will be observed that the half pattern, $l'\ o\ m\ m'$, in Fig. 4, is similar in all respects to $a'\ b'\ g'\ h'$, in Fig. 3.

In Fig. 5 is shown a method for obtaining the miter lines for elbows of any angle and for any number of pieces, also for constructing templet giving the miter lines. Let A B C represent the angle of elbow, which can be drawn as desired. From B as center strike the arc W X Y. Extend C B to Z and bisect E Z at D. Divide E D into one less number of parts than there are to be pieces in the elbow. Thus for a three-pieced elbow divide E D into two parts, as E 3'. For a four-pieced elbow E D is to be divided into three parts, and one of the divisions set off from E, as E 4'. For a five pieced E D is to be divided into four parts and one of the divisions set off from E, as E 5'. Draw A F perpendicular to A B, and from B draw lines through the points in E D, cutting A F as shown. If the elbow was to be in two pieces, B D would be the miter line. The templet A F B having thus been obtained, F B is the miter line for a three-pieced, G B for a four-pieced, and H B for a five-pieced elbow having the angle indicated by A B C. To employ the templet for obtaining the pattern of elbow by method shown in Fig. 4, set off from B on templet the diameter of elbow and erect perpendicular cutting desired miter line. The length of line thus obtained is to be used for perpendiculars $l\ o$, $m\ n$, in connection with the half circumference of elbow, as indicated by $l\ m$. In Fig. 5 the arc W X Y is drawn, and the arc E Z divided for obtaining the miter lines as a matter of convenience. Lines drawn perpendicular to A B and B Z would produce an angle similar to A B C.

On February 4 there was opened at Liverpool, England, the first elevated railroad in that country. The Liverpool Overhead Electric Railway is said to be the largest line in the world operated by electricity. The overhead structure is composed almost entirely of wrought iron, and is carried on columns, the total length being 7 miles, and the total cost something over £600,000, or £85,000 a mile. Nearly 25,000 tons of wrought iron have been used in the construction. Each train is to be made up of two or more carriages, each to seat 56 passengers, and is provided with a motor at each end. The motors are so connected together as to be controlled at either end by the driver, who will carry a key, without which the motors cannot be operated. The quantity of energy can be regulated by the man in charge of the motor, and, although any practical speed can be attained, the trains as at present arranged cannot travel at a greater speed than 35 miles per hour. There are 13 stations, built upon iron girders and columns, the platforms being about 115 feet in length by 12 feet wide, and 3 feet above the level of the rail.

The Condition of the Treasury.

The money in circulation on March 1 was $1,599,655,542, against $1,609,558,892 on March 1, 1892, a decrease of $9,903,350, or $0.67 per capita. The principal changes have been an absorption by the public of gold coin to the extent of $2,000,000, of silver dollars to the extent of over $1,000,000, of subsidiary silver to the extent of nearly $1,750,000, of Treasury notes to the extent of $50,750,000, and of national bank notes to the extent of $2,000,000. On the other hand, gold certificates in circulation have diminished over $45,500,000, silver certificates over $3,750,000, United States notes almost $8,000,000 and currency certificates over $10,000,000.

The following is a comparative statement:

	March 1, 1893.	March 1, 1892.	Changes.
Gold coin..	$409,817,138	$407,813,501	Inc. $2,003,637
Standard silver dollar...	60,432,090	59,264,520	Inc. 1,167,570
Subsidiary silver.....	64,021,838	62,308,717	Inc. 1,713,121
Gold certificates...	114,388,729	160,001,279	Dec. 45,612,550
Silver certificates.	321,279,132	325,141,186	Dec. 3,862,054
Treasury notes ...	126,447,613	75,718,553	Inc. 50,729,060
United States notes ...	314,174,742	322,131,688	Dec. 7,956,946
Currency certificates	19,250,000	29,350,000	Dec. 10,100,000
National Bank notes...	169,844,260	167,829,448	Inc. 2,014,812
Total..	$1,599,655,542	$1,609,558,892	Dec. $9,903,350

From this table we see that there is a loss of about $62,506,000 in gold coin and bullion, which has been partly replaced by $42,750,000 of silver coin and bullion. The decrease in holdings of subsidiary silver and Treasury notes is about offset by an increase in United States notes. The total cash in the Treasury is $16,500,000 less than a year ago.

There are outstanding $440,622,355 of obligations demanding repayment in gold (exclusive of gold certificates) against which the Treasury holds $103,284,219 in free gold. This is 23 4 per cent. of the liabilities, as against 30.1 per cent. on March 1 last year and 24 38 per cent. on February 1.

Following is a comparative statement:

	March 1, 1893.	March 1, 1892.	Changes.
Gold coin	$137,857,000	$198,847,863	Dec. $61,009,963
Standard silver dollar..	358,474,895	352,920,220	Inc. 5,554,675
Subsidiary silver....	10,971,878	14,787,882	Dec. 3,816,956
Treasury notes....	5,420,240	9,517,659	Dec. 4,097,419
U. S. notes	32,500,274	24,549,328	Inc. 7,956,946
Nat'l bank notes....	5,578,128	4,792,427	Inc. 785,701
Total.	$550,789,313	$605,415,329	Dec. $54,626,016
Gold bullion.....	$79,835,048	$81,194,377	Dec. $1,359,329
Silv. bullion.....	102,973,771	65,720,466	Inc. 37,253,305
Total.	$733,598,132	$750,092,315	Dec. $16,494,183

THE RETAIL STORE.

The Stove and Tin Business. II.

BY VETERAN.

The competition of dry goods and furniture dealers is a matter of importance to every retail dealer in large cities where these establishments handle stoves and house-furnishing goods. So far as the sale of stoves by furniture dealers, on the installment plan, is concerned, they are welcome to it, for it never has and never will pay any stove dealer to sell stoves to irresponsible parties on what is called the installment plan. I make a distinction between that and the ordinary credit given to people who are known to the dealer and want a short credit. The furniture dealer sells a bill of goods amounting to enough to pay for the papers giving him a lien on the goods and to send his collector as often as need be, and he is comparatively secure, and he usually charges 25 per cent. over cash prices for the stoves. So far as my personal experience goes, this kind of competition is a help to me, for people who have visited these stores find my full cash prices so much below theirs that it advertises me as a low-priced dealer, and I think there are many cases where the furniture dealer relieves me from running after the pay by doing it himself.

The credit system is an unmitigated curse to trade, as a rule. If people cannot pay for goods they had best go without them. If any one will notice the successful merchants around them they will see that they are men who were very careful about giving credit, while it is a fact that among bankrupt concerns a large part of the assets are worthless accounts that no creditor would take in settlement at 25 cents on a dollar. Not only is the dealer who trusts out his goods doing an injustice to himself and his creditor, but he also commits a moral wrong by encouraging others to burden themselves with debts.

The case with house-furnishing goods sold by the dry goods dealer is different. This trade is a cash transaction strictly, and when the wonderful prices they claim to make are investigated it is seen that they are not so low after all. As a rule they charge round prices for all heavy tinware and other goods that have no second qualities. They purchase agate ware at auction, but it is only seconds that are sold that way. When they really do put a low price on these goods the retail dealer can buy them in small quantities from them at 10 per cent., which is better than nothing, and is the only way he can compete, as the auctions only sell full cases.

There is only harm in making complaints. What sense is there in a man telling every body that the dry goods stores are ruining his business? We live in a day of sharp competition, and a few dollars made from tin ware, agate ware, hollow ware, and notions is a help, and the palatial dry goods establishment will not send any men out to clean furnaces or put up smoke jacks, and such work must be made to pay, and no one will find fault, but to charge 5 cents too much for a tin pan will drive away customers.

I suppose it would sound like nonsense to advise every stove dealer to do the best he can when he meets obstacles, but it is really one of the most difficult things imaginable to do the best one can. It means that the dealer shall keep his head clear, give his whole time to his business, see to his workshop that it is kept well supplied with tools and stock, that work is done when it is promised, that his prices are as low as other reliable dealers are, that he makes and holds a good share of his trade by personal effort, sociability, and pleasant manners, and that he is not carried along by the tide, but has the stuff in him that can run against the tide, and that when he spends money it shall be money that belongs to him.

Peck, Stow & Wilcox Company.

In the Columbian edition of the catalogue of Peck, Stow & Wilcox Company, of tinsmiths' tools and machines, just from the press, while many new goods have been added in different parts of the book, suited to many branches of sheet-metal industries, our attention is especially attracted to several leading lines that have been largely increased. In forming machines a great number have been added which while not new in principle, perhaps, are now offered for a number of uses not before obtainable from this source. A feature that has received much attention is the adaptation of the slip roll method and many formers permitting work to be slipped off the end instead of sprung over the roll, which often impaired the quality of the work. There are a great many large formers for heavy work to be operated by steam power, while a number of rolls for short lengths can now be furnished. The line of corrugating and crimping machines, 30 in number, for hand and steam power, ranging from 3-inch rolls 8 inches long to rolls 8 inches in diameter and 72 inches long, are new with them. The collection of squaring shears now offered should satisfy the most exacting and are made to meet any reasonable requirement in this department.

W. J. GOFF AND FRED. J. TAYLOR of Malone, N. Y., have formed a copartnership and will carry on a general tin, stove, and plumbing business on East Main street in the store occupied by Mr. Goff. Mr. Taylor has been mail clerk on the Central Vermont Railroad. Mr. Goff has for many years carried on an extensive stove and plumbing business and has been prosperous. The new and energetic firm have an auspicious start.

How to Avoid the Accumulation of Dead Stock.

FIRST ARTICLE.

By H. P. TOWNLEY.

We have been 20 years in business wrestling with dead stock, and we are pleased to give you an account of the numerous plans and schemes whereby it was made to go. During these years we have bought four stocks of goods from assignees and have thus gotten more of the stuff than we would otherwise have had. Our experience has been that it is not desirable to buy goods in large quantities in order to obtain low prices. The greater advantage lies in having the goods come to the shelves fresh, in having less capital invested and in being able to take the cash discounts.

CARE IN BUYING.

We endeavor to buy carefully and judiciously (especially if the article is new to us and no demand yet established) and thus feel the trade. Should it prove a seller the order can easily be duplicated.

ANNUAL INVENTORY.

We take an annual inventory, which we consider very important, as it brings into view all stock both good and bad. From this inventory we make list of all dead stock. The list with its quantity and cost price is put on heavy cardboard and tacked up in our office, reversing the maxim "Out of sight, out of mind." Thus we have the dead stock in daily view and by keeping everlastingly at it we succeed in getting well rid of it.

SLAUGHTER SALES.

We have on several occasions advertised "Slaughter sales—great reduction in prices at close of the season." This has never been successful with us. We prefer to carry such goods over to another season and yet get the profit on them when they are sold. Slaughtering prices will demoralize the trade of other dealers as well as our own.

INTRODUCING GOODS.

Small articles are put in the most conspicuous place in the store, namely, on the showcase or on a table near the door, with plain tags on them and our clerks instructed to call the attention of every one who enters the store to them whether customers or not.

JOB LOTS.

We frequently make up job lots for second-hand dealers. We will lay on the floor a pile of goods of which one-half is dead stock and one-half good—the good being put in for a bait. We then call in

our two-handed brethren and work them for $3 or $5 for the lot, as the case may be. One year we sold a gross or more old, old lanterns which would hardly pay their own drayage.

PREMIUMS.

We have used the "PM" system (PM being abbreviation for premium). Each article is marked with a peculiar tag. As the article is sold the clerk keeps the tag till the end of the month, when the cashier will redeem it at the agreed price, the PM money being over and above his salary. We have known clerks to earn $3 to $4 per week extra in premiums.

PRIZES.

To crowd the sales of Stoves we have offered three prizes—viz., $20, $10 and $5—to the clerks who would sell the greatest number, up to January 1.

CONSIGNMENT.

One year we were carrying 13 hard-coal Base Burners which we had taken back on trades. As this is a great soft-coal country these Base Burners were likely to become stickers. We shipped them to a commission auction house in Chicago. After paying freight and liberal commission we came out ahead.

DAILY REDUCTIONS.

Another year we used the 50-cent reduction plan.

The following placard was put on a Stove on the sidewalk.

GREAT SCOTT!!

This Stove will be reduced

fifty cents each day

until sold.

Price to-day, $12.50.

The cost price on the first Stove experimented on was $8. A customer was ready for it bright and early on the day it was marked to be sold for $8.50. The record of 20 of these sales shows that we came out a little above cost. With each Stove extra pipe, tinware, &c., was sold.

COUNTY FAIR PREMIUMS.

Our county fair has helped us to run off some Patent Bread Cutters and Patent Washing Machines by offering them as special premiums for the best layer cake or the largest pumpkin, the cake to go to the dealer. We considered this scheme successful on account of the advertisement there was in it.

Leggett's Liquid White Glue.

Leggett & Brother, 301 Pearl street, New York, are putting liquid white glue upon the market, illustrations of the styles of the packages being shown herewith. The glue is put up in 1 and 2 ounce bottles as in Fig. 1; and in 4 ounce, ½ pint and 1 pint cans, Fig. 2, with brush attached in all cases. The manufacturers remark that the glue as put up is ready for use and may be thinned with water without injury, that it will keep in all climates without spoiling and with no unpleasant odor, and that it does not thicken or freeze in cold weather or become thin in warm weather, and is not affected by changes in the atmosphere. It is recommended by the manufacturers for wood work, carriages, emery wheels, belting, &c., and may also be used for mending crockery and glass. It is stated that the glue does not crimp or crinkle paper, may be used for labeling on tin or glass, and that articles

Fig. 1.—Liquid White Glue in Glass.

upon which it is used do not fall apart in damp, sultry weather. The corks, with brush attached, are prepared to obviate their sticking to the glass or tin. The glue

Fig. 2.—Liquid White Glue in Tin.

is also put up in tin cans with double cover, in 1 quart, ½ gallon and 1 gallon sizes.

Hyatt Cabinet Locks.

Brass Goods Mfg. Company, 92 Third street, Brooklyn, for whom J. H. Walbridge & Co., 43 Leonard street, New York, are sole agents, are introducing locks as shown herewith. The feature of these locks is the entire absence of springs and the thinness of the working parts—the bolt being thrown by an eccentrical shaped thin piece of metal, into which the key fits. The wardrobe lock, Fig. 1, is made in three sizes: 1½ x 2¼, 1¾ x 3 and 2 x 3½ inches; also in sizes 1 inch wide, longer and narrower than the foregoing, suitable for library doors, &c. The locks represented by Fig. 1 have broad bolts, which shoot both right and left, and are provided with combination union key, having a round bit and flat shank, thus giving additional security to the lock. The locks have a self-centering keyhole, boring for which simply requires a $\frac{7}{16}$ bit.

Fig. 1.—Hyatt Wardrobe Lock.

The locks are made entirely of steel, finished both in natural steel color and in bronze, with one key for each lock. The lock, including bolt and casing, meas-

Fig. 2.—Key for Wardrobe Lock.

ures $\frac{3}{16}$ inch in thickness. The cylinder drawer lock, Fig. 3, is finished in steel and bronze, and is made in two sizes, 1¾ inch and 2½ inch wide. The escutcheon fits a hole bored with a $\frac{7}{16}$-inch bit, is self-finishing and is adapted for drawers

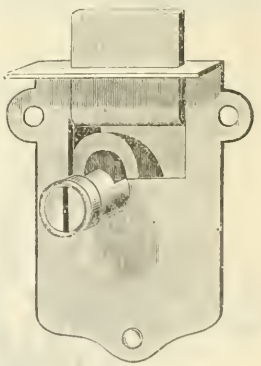


Fig. 3.—Hyatt Cylinder Drawer Lock.

having ¾-inch fronts. The amount of cutting out required to accommodate this lock is very small, being less than $\frac{3}{16}$ inch. The locks are provided with flat steel keys—one key to each lock of steel finish

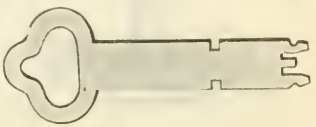

Fig. 4.—Key for Cylinder Lock.

and two keys to each bronze-finished lock, with 12 changes to a dozen.

The cuts shown are full size representations of the locks and keys. German drawer locks of similar construction are also made by the company.

Meat Choppers.

The Enterprise Mfg. Company, Philadelphia, Pa., have placed upon the market a new No. 3 Enterprise meat chopper, as

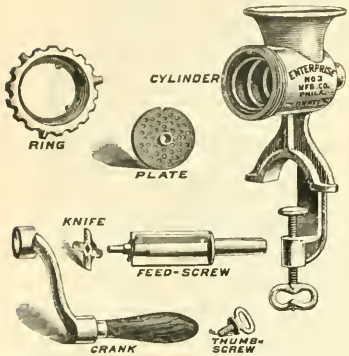

Fig. 1.—No. 3 Enterprise Meat Chopper.

shown in Fig. 1. While the outward appearance of the chopper resembles their old pattern, the principle of forcing the

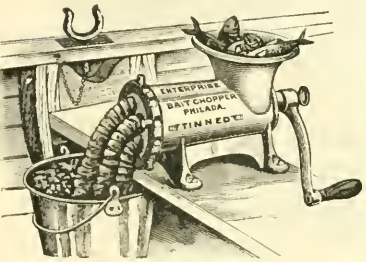

Fig. 2.—Bait Chopper.

meat to the perforated plate is practically a reversal of that formerly used. The cut shows the interior of the cylinder or

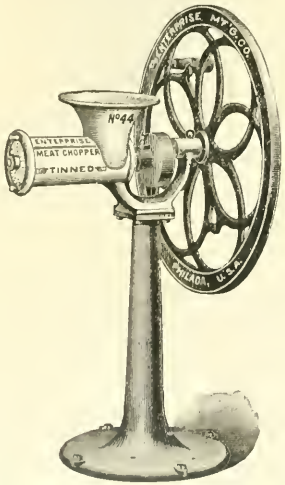

Fig. 3.—No. 44 Meat Chopper.

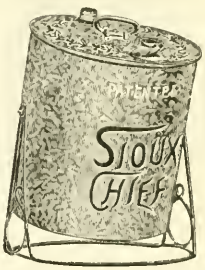
casing, grooved after the style used on the feed screw in the old pattern, while the feed screw used in the new pattern has straight edges. It is claimed that the new principle in this chopper will better adapt it to household uses.

To meet a special demand, the same company have ready for the market a bait chopper, Fig. 2, which is of the same size as their No. 32 meat chopper, but is fitted with a short crank, and a plate with large holes. It is intended for use by fishermen, and is especially useful in "chumming" or "baiting" up any particular spot by spreading over the waters chopped menhaden, hardhead and other bait.

As a third novelty, the company are introducing a chopper mounted on a column, Fig. 3, and adapted to the uses of butchers and hotels. It is to be catalogued as No. 44, and is their No. 42 in a new form, provided with reversible gearing, capable of adjustment for driving the feed screw faster or slower than the crank wheel, as may be desired.

Sioux Chief Oil and Gasoline Can.

The can illustrated herewith is manufactured by F. C. Wilson & Co., 239-241 Lake street, Chicago, Ill., and is being



Sioux Chief Oil and Gasoline Can.

introduced by them. It is made of galvanized iron, neatly finished and ornamented, and is provided with a faucet and a tin cork lined filling screw. The stand in which the can is hung is made of No. 6 wire, japanned black. The point is made that the stand is very strong and that it may be utilized for hanging the can upon the wall, so that a child can handle it. The cans are papered and packed in quarter dozen crates.

John Lapp, Rochester, N. Y., has patented an improvement in steam boilers and heaters. The boilers consist of vertical two-piece sections, the water space being within the sections and communicating through suitable heads.

Home Tacks.

The accompanying illustrations represent the packages containing home tacks as put on the market by the Atlas Tack Corporation, Boston, Mass., and 116 Chambers street, New York. Fig. 1 shows the case containing 12 cartons of tacks, the case

Fig. 1.—Case of Home Tacks.

being about 8 x 12 inches in size and 2 inches deep. The cover of the case is held open by tapes, and the inside and outside of the cover are handsomely lithographed in colors, making an attractive display upon counters, shelves, and in showcases, show windows and sample rooms. The front of the cover is the same depth as the box, lithographed in colors, and presenting a pleasing appearance when the cover is closed. The 12 cartons, one of which is shown in Fig. 2, are an exact reproduction in miniature of the case, including colored lithographing, and each contains two boxes 8-ounce, one box 10-ounce, one box 12-ounce carpet tacks,

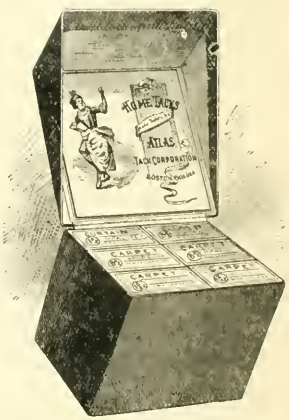


Fig. 2.—Carton Taken from the Case.

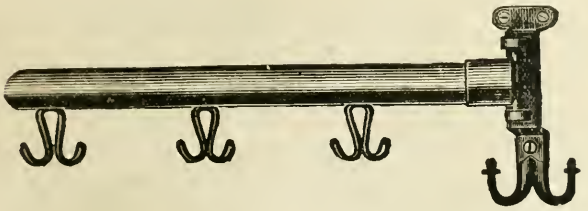
one box gimp tacks and one box curtain tacks. The tacks are especially assorted for home uses, and the cartons containing the six boxes are designed to retail for 25 cents each, or single boxes of tacks may be sold for 5 cents each. The point is made that the sales of tacks can be increased, as customers may be induced to buy a carton of six boxes instead of purchasing only one box.

The Champion Hinged Clothes Bar.

The illustration here shown is of a hinged clothes bar put upon the market by the Besel Patents Company, 133 South Second street, Philadelphia.

The bar swings in a hinge which is easily affixed by three screws to the back of a wardrobe or closet. There are double hooks on the bar, so arranged as to allow of garments being hung quite closely.



The Champion Hinged Clothes Bar.

The novel feature of the bar is that it allows of the garments on each hook being readily viewed or examined without removal. The capacity of the wardrobe, too, is more than doubled.

The cut shows the bar ready for adjustment. Bars are made in a variety of sizes, and are therefore adapted to any wardrobe or closet.

A Cash System.

In the Retail Hardware establishment of R. B. Owen & Sons, Detroit, Mich., signs are hung on the gas fixtures, the object being to clearly inform customers of their system of doing business. The signs are as follows:

We sell for cash only.

Goods cheap for cash.

Do not ask for credit.

We prefer our goods to credit.

Before starting business, nearly a year ago, the above firm decided to do a strictly cash business, and have carried out their intention to the letter. In a communication from them they refer to the matter as follows:

Relating to the "cash system," we were led to decide to adopt the same exclusively from the great majority of builders and contractors being very slow pay, even if worthy of credit at all. In this city we have over 700 boss builders, and not to exceed seven, if over five, are worthy of credit. From the fact that a new business would be very anxious to open trade we recognized the fact that we would be overwhelmed with people desiring credit, to whom we would be very apt to extend the same. We were counseled by a number of our friends that our decision was impracticable, but after the trial given the experiment we are more convinced than ever that we are right. We are aware that we could sell a much larger quantity of goods on the credit basis, but we find we sell a great many goods to people simply because they do not owe us, as it is human nature to shun a store to which we are indebted. We compel all bills to be paid for either at the time of purchase or upon delivery to the buildings. Our builders are fast becoming educated that it is the wisest thing for them to do to pay cash, as they buy their goods cheaper and buy only what they absolutely require. We shall strictly adhere to the "cash system," and unequivocally pronounce same a success.

The fact that a retail Hardware business is being successfully carried on upon a strictly cash basis, and that goods are not delivered until paid for, is of especial interest to the Hardware trade. That such a business is being done in a city where other Hardware stores are offering credit lends additional interest to the undertaking. The reasons given why it was decided not to do a part credit and part cash business exist in every community, and we suggest that any merchants who are dissatisfied with credit business consider the advisability of making a change to cash on or before January 1, 1893. Limiting credits first to 60 days, and then to 30 days, customers may gradually be prepared for the change to a cash basis.

Bradley Shelf Bracket.

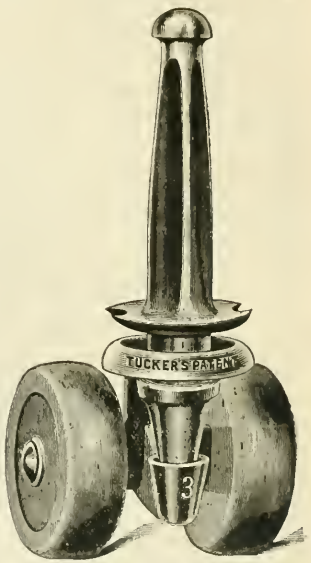
Atlas Mfg. Company, 71 Hamilton street, New Haven, Conn., are putting on the market an improved form of their Bradley bracket, as herewith illustrated. In the improved form the screw holes on the long side of the bracket are side by side, instead of one over the other, as formerly. This is referred to by the makers as an advantage, as the holding power of both screws is now fully utilized, and the convenience in handling and driving the screws is much greater than in

Bradley Shelf Bracket.

the first form, where the holes come directly behind the brace. The point is made that the present form also secures a much wider bearing sideways, and adds to the symmetry and correct proportions of the bracket. The bracket is described as light and artistic in design, finely finished, having more strength than the same size cast-iron bracket; as not being brittle, and not breaking in shipping or in driving the screws from the warping of a shelf or from a sudden blow, and as saving 75 per cent. in the cost of freight. The brackets are made in 4 x 5, 5 x 7, 6 x 8, 7 x 9 and 8 x 10-inch sizes, and have a tin finish.

Tucker's Improved Furniture Caster.

The caster represented in the accompanying cut shows an improved construction, introduced by the Tucker & Dorsey Mfg. Company, Indianapolis, Ind. In the improved construction all washers and screws have been done away with, and the caster consists of but two pieces of malleable



Tucker's Improved Furniture Caster.

iron, besides the wheels and axle. The loop in the housing is simply pressed around the stem, so it is stated that while there is freedom of movement and perfect oscillation, yet the stem is held securely in place. Attention is also called to the new fluted Fox stem, which, it is claimed, makes a perfect drive stem, in addition to being expressly designed for use with the Fox socket and track plate. The point is made that the caster is extremely simple and of the most desirable design and finish.

MEMORANDA.

THE HARDWARE FIRM OF CASH & BRADFORD, Hyannis, Mass., have been dissolved Mr. Cash retiring after having been in business since 1866. Mr. Bradford, who has been associated with Mr. Cash for the past seven years, will continue the business in a part of the new block soon to be erected on the site of the one which was recently destroyed by fire. The new block will be four stories high on Main street and will cover 8000 feet of land. Mr. Cash will for the present devote his attention to building matters.

F. H. EWALT, J. E. COOPER AND C. C. EWALT have organized at Manhattan, Kan., the firm of Ewalt, Cooper & Co. The new firm will commence business about March 15, and will carry a line of Builders' Hardware, Cutlery and general Hardware. Plumbing will also be a part of their business. The new firm will be pleased to receive catalogues and other printed matter issued by manufacturers and jobbers in their line.

THE BUSINESS formerly conducted by Murphy, Cole & Bain, retailers of Hardware, Tinware, Stoves, &c., Bethany, Mo., is now carried on under the style of J. L. Cole & Son.

STOVE TRADE NOTES.

Claims for Castings Broken in Shipment.

The question of unjust claims for breakages of stove castings in shipment is one which has from time to time received more or less attention in these columns, but from the numerous letters received from members of the trade, suggesting a discussion of the subject in *The Metal Worker*, it is probable that much more might be said to the advantage of all concerned. We trust, therefore, our readers will consider this an invitation as applying to them individually, and will send us letters expressing their views of the questions raised. One writer under recent date urges a discussion of the subject of unjust claims for breakages in shipment, and says:

"When a dealer writes us, as one of ours did, for a set of coal fixtures for a range, claiming that he bought the stove for wood only and the wood fixtures cracked all to pieces, his customer concluded he would burn coal, and now wants coal fixtures at a reduced price, or free—I think it is about time some articles from the trade papers were turned in that direction."

Another correspondent gives extracts from letters recently received by his firm relative to the same subject. Among them are the following:

"The deductions made for castings was for bottom of —— broken. Although it was only a small piece my customer refused to pay unless I put on a new bottom."

"I received last evening the No. 7 —— stove, but found there was an apparent crack in the front door near the hinge. Not thinking you would want me to have that, I send it back for examination."

It is probable that nearly every stove manufacturer in the trade could furnish innumerable instances of this general character, and also that he has pretty well defined ideas as to who should bear the loss in cases of this kind. A writer, well informed by reason of his long connection with the stove trade, and who is qualified to speak authoritatively, expresses views concerning the justice of claims of this character made upon the stove manufacturer, which are full of interest to all in the business. It is his belief that if claims of this kind are allowed it is simply on the score of policy, and that the wholesaler will pocket the loss for fear that by entering into a controversy over the matter he might lose a customer. He continues as follows:

"It is, nevertheless true that such claims are becoming more and more frequent and causing much loss to the wholesalers. Firm ground should be taken by them to resist such claims, for their own protection and preservation of profits. One large house some months ago published a circular, which was sent broadcast throughout the trade, and which, we understand, has been generally accepted and respected by their customers. It reads as follows:

SPECIAL NOTICE.

As questions are always arising relative to breakage and damage to goods in transit, and as there seems to be a feeling more or less that the shipper and not the carrier should be responsible for the safe delivery of goods at their destination, we find it necessary to notify our customers and the trade generally that, while we are willing to assist them all we can in adjusting claims or recovering damages, we must positively decline to entertain or allow any such claims if made upon ourselves, as our responsibility ceases as soon as goods are delivered in good order at railroad depot or wharf, and a receipt taken for the same.

Our goods are not only carefully packed by experienced packers, but must be all passed by a competent examiner, thereby insuring that goods are in perfect condition when sent out; consequently we cannot admit the claim so often raised, that they have been damaged in transportation because not properly packed or boxed, when the damage is the result of improper or careless handling on the part of the carriers.

In the absence of any special instructions, goods are shipped released, thereby the lowest freight rates are procured. Parties desiring their goods shipped not released or packed or shipped in any particular manner, should send instructions with each order.

Goods will not be received by us unless returned by our permission; and unless it has been otherwise arranged, party returning goods must in all cases pay freight and expenses, and be responsible for any damage to the goods until the same are received by us.

If other manufacturers would adopt a similar course it would undoubtedly go far toward establishing a fixed rule which the dealers would understand to be inviolable, and one by which they must abide—or it may be more correct to say it would revive or re establish a very old rule which, by the weakness of stove manufacturers, has lost its force; and, if unjust claims continue to be allowed by them, will drop into innocuous desuetude in a few years more.

The loss of money by allowing such claims is not the only ground of injustice felt by the manufacturer, but the case is aggravated by the fact that he pays what the Transportation Company should pay—for it frequently happens that a dealer will write to the wholesaler, when a stove arrives broken, that he refused to receive it and ordered the transportation agent to send it back; that he did not propose to fight the railroad company, so thought the best way out of it was to let it go back. There are others who do not even deem the manufacturer as entitled to the courtesy of a written notification of its return, and the shipper—perhaps two or three weeks after the original shipment—is notified by the carrying company that a stove is at the freight house marked for him. The original shipping tag may be absent, and much difficulty is often experienced in ascertaining from whom it comes; and sometimes the sender is not known until the monthly statement of account is returned by some dealer who is highly indignant at being asked to pay for a stove he never received. He is occasionally mad enough, at the outrageous conduct of the manufacturer, to close accounts and never buy another dollar's worth of goods. Letters of explanation to men of this class amount to nothing but wasted time and money.

As a matter of fact there is no other established rule of business or relationship between buyer and seller that is so often ignored or abused as the responsibility for damage in transit. Prices, discounts and terms of sale, though sometimes the subject of dispute, do not come up to disturbe the business intercourse or friendly relations between buyer and seller once where the matter of breakage comes up a dozen times. Of course prices and terms are generally fixed by written quotation or written in manifold books by travelling salesmen, and duplicate of sale and terms left with the customer, but the conditions of shipment, or in other words, the responsibility in case of loss or damage in transit is frequently as explicit and plain, as many firms have printed on their invoices the following expression: "After obtaining a receipt for goods shipped in good order our responsibility ceases. If loss or damage occurs in transit the consignee must look to the Transportation Company for redress."

Every case of indifference on the part of the consignee, or shifting the responsibility upon the shipper, encourages future carelessness and independence of the carriers; for the shipper, on whom the burden is thrown, is without proper proof of the true condition of goods on arrival when refused by the consignee, and too often he is obliged to stand it all, because the claim would be weak from lack of assistance from or indifference of the one who really should have made the claim.

DEALERS SHOULD EXAMINE GOODS.

If dealers would examine goods carefully on arrival before removing them or receipting for them and give a conditional receipt or note in signing the number of stoves or other articles broken, thus laying a good foundation for their claim, they would not experience much disappointment in having it allowed. If they would all do this regularly, taking care to find even the smallest break and render a claim therefor, it would not be long before an improvement in the service of every carrying company would be noticeable, for it would be cheaper to get better freight handlers and otherwise improve the service than to look after accumulating claims.

It seems a pity they should so often be assisted to go scott free of all responsibility.

If the printed notice on bill heads goes for naught—and it often does, as the buyer claims that all the conditions of the sale should be known to him in advance of, not subsequent to delivery—then it would be advisable for the wholesale houses to have shipping conditions or conditions of responsibility printed on their letter heads, catalogues, price lists, circulars, and all literature that circulates to the dealer prior to his giving his order.

In this way no dealer could put forth the same excuse that he supposed the goods were to be delivered in perfect condition to his station or wharf, and the rule of the wholesale merchant would be so well advertised that such a contention would have no leg to stand on if made, and the custom of any dealer making it could well be dispensed with.

(*To be continued.*)

Thomas A. Westcott.

At a meeting of the stove manufacturers of Boston, held on Saturday, February 25, at the office of the Magee Furnace Company, a series of resolutions were adopted in memory of the late Thomas A. Westcott, who, until the day of his death at the age of 70, was actively engaged in the stove business. The resolutions adopted read as follows:

WHEREAS, Death has removed from our midst our valued friend and business associate, Thomas A. Westcott,

Resolved, That we, stove manufacturers and jobbers of Boston, recognize in his death a loss sustained by the business and social interests of the community where he lived, and where he was everywhere esteemed as an honorable business man and useful citizen.

Resolved, That we close our places of business during the funeral hour.

Resolved, That a committee of our number be appointed to attend the funeral.

Resolved, That we tender to his family our condolences in this their bereavement, and transmit to them a copy of these resolutions, and publish same in the daily press.

D. W. Cushing, S. M. Howes, J. R. Prescott, Committee on Resolutions.

Courtesy in Letter Writing.

Not the least difficult work of the man of business is to write letters to disgruntled customers and explain away disagreeable occurrences. Where the customer is in the right it is an easy matter to acknowledge it and make the proper restitution. But the hard work comes when the customer is manifestly in the wrong, but yet has to be treated judiciously, and, we may say, tenderly, lest his feelings be so hurt that he transfer his trade elsewhere. The amount of self control shown in correspondence of this nature, where moneyed interest is at stake, is incredible did not every one's own experience prove it to exist. Not a few business men of naturally hasty temper make a practice of writing, or, at least, of outlining a letter first that expresses exactly the state of their minds without any regard to the amenities of correspondence. This first draft, being kept for 24 hours and destroyed, is replaced by a second polite and carefully-worded letter that accomplishes the purpose that the first would have frustrated. The result of these courteous notes, where the occasion would seem to warrant anything but gentleness, is so uniformly of advantage, that we should think more expediency would prevail and keep every business note free from any trace of ungoverned temper. This trait of courtesy in correspondence, verbal and written, is like the quality of mercy, a blessing to both parties to the intercourse. It becomes the business monarch, and is an invaluable possession to his lowest clerk; it is a factor of economy in the conduct of busines that cannot be overestimated. And the wisdom of this good rule is never so clearly emphasized as when a fit of sudden passion shakes seasoned business men out of their well tried manner and drags them into correspondence of invective and personalities.

THE BUCKS STOVE & RANGE COMPANY of St. Louis, Mo., send us a four-page circular in which the history of the Bucks stove is briefly presented. It is stated that "46 years have passed since the first Bucks stove was made, and, looking back to that day and comparing the stoves then made to the Bucks brilliant stoves of the present day, we more than realize that this is an age of marvelous progress." Reference is made to the fact that many of the practical ideas to be found in Bucks stoves and ranges are the result of years of practical experience, investigation, and the expenditure of large sums of money. In conclusion the circular, which is signed for the company by J. W. Van Cleave, manager and treasurer, extends an invitation to all dealers to examine into the merits of the company's goods and to write them for any and all information that may be desired.

Robert Schueler & Co.,

manufacturers of American gas stoves, 615 Ogden avenue, Chicago, have issued a new catalogue and price list. Their leading product is the American gas range, which is shown in a variety of styles and sizes. It is a full cabinet range, the body being made of cold rolled heavy refined steel, with cast iron front, top and doors. The oven is heated by double radiating burners placed underneath a sheet of steel, half an inch from the oven bottom, which prevents the flame from the burner coming in direct contact with the oven bottom. The flues are so arranged that the heat passes up both sides over the top and down the back, escaping at the flue in back, thus exposing every part of the oven surface to the action of the heat, while the fumes from the burning gas do not come in contact with the contents of the oven. The burners are of the latest design, having no loose caps to cause leakage of gas. An automatically hinged drop oven door forms a strong and convenient shelf when open. The cooking holes have covers and removable grates. Nickel has been judiciously used in ornamentation. The highest grade range of this type is provided with a back rail, to which are attached nickel plated swinging tea shelves. Variations of this range are shown in the catalogue, having water heater at the side, with two cooking holes over it, a high broiler or a high shelf. Cheaper grades are made in three styles, with either two, three or four burners on top. The line of table stoves includes three styles, respectively known as American Junior, with cast tops; Columbia stoves, with japanned steel tops, and Enterprise stoves, cast in one piece. Heaters are also shown in various styles and sizes, embracing both square and cylindrical constructions.

ODD PLATES.

THE PERRY STOVE COMPANY, for years at 74 Beekman street, are about to move into more commodious quarters at 103 Beekman street, where their manager, A. A. Thompson, will, after May 1, be pleased to see old friends and make the acquaintance of many new ones. The Gipsy and Hero portable ranges (one a modification of the other) have lately been improved and will in future be known as the New Gipsy and New Hero. We are told this pattern in New York and the immediate neighborhood for 1892 reached a sale of 4800, and 6000 could have been sold if the increased wants of the trade could have been anticipated. The improvements referred to consist of a swelled oven door, fire and ashpit door, together with a handsome name plate with tile ornaments. The New Gipsy can be supplied with or without base skirting and now has a foot pedal or oven door opener, formerly used only on more expensive ranges. They also have a full line of samples of Royal oil and lamp stoves which through recent improvements introduced in manufacture the company are enabled to sell at a less price than formerly. The Improved Dandy low gas stove of 1893 is now ready for shipment.

A DISTRESSING accident occurred late on the afternoon of Thursday, February 23, at the works of the Abram Cox Stove Company, Dauphin and American streets, Philadelphia, Pa. A gang of workmen were employed in tearing down a two story stable adjoining the stove works, in order to make room for improvements by which the plant is to be increased. Suddenly one of the walls of the building fell instantly killing two workmen, while a third was seriously injured.

THE MICHIGAN STOVE COMPANY favor us with a sample of the advance cards sent out by their salesmen to announce to customers that they may soon be expected to call. The one before us is in the form of a dainty pamphlet containing four leaves, bound together with silk cord. The salesman's announcement is on the front page of the cover, which is of heavy white paper, with a serrated edge. The inside pages contain a well worded argument in favor of the exclusive sale of Garland stoves and ranges.

WE ARE ADVISED by C. T. Boal that the C. T. Boal Stove Company, who have long conducted an extensive business at 245 and 247 Kinzie street, Chicago, have closed up their business. As they owed no debts it was found an easy matter to "quietly quit." Mr. Boal was for many years the Western representative of Orr, Painter & Co., of Reading, Pa, and also manufactured the Henrietta line of stoves at Chicago. He is well and very favorably known to the trade at large, and his many friends will hear of his retirement with regret. Our best wishes go with him in whatever channel he may see fit to enlist his energy in the future.

AT THE HEADQUARTERS of the Union Stove Works, on Beekman and Gold streets, the managers are busily engaged in renovating and improving the interior in the way of painting, readjusting samples and otherwise getting ready for an increased trade which they confidently expect. They have introduced among other things a system of pneumatic tubes designed to save time and facilitate the transaction of business, and propose to be up with the times and down to date.

H. RENDTORFF & Co., 16 Lake street, Chicago, have brought out a very handsome circular, illustrating and describing their Ideal wrought steel range. The illustrations show it with high closet, with high closet and water tank on side bracket, with high shelf, &c. Three sizes are made with six cooking holes and one size with four holes. The flues are asbestos lined throughout, and the ovens are thoroughly braced and bolted. They are adapted to any kind of fuel and are elegantly finished. A supplement sheet to their catalogue has also been issued which gives descriptions and prices of the Home Ideal cook stove, which is furnished in two sizes, either square or reservoir extension, adapted to hard or soft coal, and is offered to meet the demand for a cheap stove.

THE CORNING STOVE COMPANY of Corning, N. Y., are enjoying something of a boom just at present on their line of Garnet stoves and ranges. We understand that the works are crowded with orders, every department being pushed to its utmost capacity. Another gratifying feature in connection with this condition of affairs is that the warehouse is depleted of its stock of finished goods.

THE RIDGWAY FURNACE COMPANY, 76 Union street, Boston, Mass., were awarded a gold medal at the Massachussetts Charitable Mechanics' Association "for superiority and economy of their hot air furnaces." It is stated that this is the only furnace which has received a gold medal from the association named for the last 35 years.

ACCORDING to a local paper the invoice of the Girard Stove Works at Girard, Ohio, has been completed, showing the condition of affairs to be as follows: Bills payable, $55 000; accounts payable, $23,000; good assets, $15,000. Capital of company, $15,000. It is now said to be regarded as probable that the plant of the company

will be sold and purchased by the creditors who hope by operating it to save something from the wreck. The appraisers of the works appointed by Judge Robinson were C. D. Goodrich, W. J. Wallis and Henry Hartzell.

THE MARCH-BROWNBACK STOVE COMPANY of Pottstown, Pa., began last week to run their works full in all departments in order to keep up with orders. We understand that the prospects are such that there is not likely to be any let up before the first of July.

THE WARREN HARDWARE COMPANY of Warren, Ohio, held their annual meeting a short time since to elect officers and declare a 6 per cent. dividend for the year. We understand that the trustees decided to enlarge their works and increase the steel range business of the company.

THE J. S. & M. PECKHAM COMPANY of Utica, N. Y., have been incorporated under the laws of the State of New York for the purpose of manufacturing stoves, furnaces and agricultural implements. It is stated that the new concern assumes all the liabilities and assets of the firm of J. S. & M. Peckham. At the meeting of the stockholders Merritt Peckham, Edwin Peckham, Frank Peckham, Merritt Peckham, Jr., and W. C. Walker, all of Utica, were elected directors. Subsequently the directors elected Merritt Peckham, president; Edwin Peckham, vice-president, and W. C. Walker, secretary and treasurer. The capital stock of the company is said to be $100,000.

THE FEBRUARY ISSUE of the *Gasoline Stove Bulletin*, devoted exclusively to the interests of George M. Clark & Co. of Chicago, is designated as the 1893 Catalogue Number, and in it everything they make is illustrated and described. It is made up of 16 pages printed on tinted paper after the general style of its predecessors. It is full of interesting matter relative to the goods manufactured by the company named and presents illustrations of a wide range of Jewel stoves. Upon what may be termed the editorial page the statement is made that the policy of the publishers of the paper with regard to travelling men has been somewhat modified. There are now three representatives who will work on gas, oil and gasoline regularly, but in no stated territory. This is also the first number of Volume V, and in it the company present their annual greeting in which, among other things, they state that they have taken a new building 50 x 130 feet in size, five stories and basement in hight, which will enable them to double their output. Their line has been increased by the addition of a cabinet process range, a two and three burner low stove with a lay-down tank in both the junior and Acme styles, a two and three burner medium stove with a single generator, and a cake griddle which in the estimation of the manufacturers is simply "perfect."

THE CHICAGO TRADE in coal and wood ranges and cook stoves is by no means brisk. The house is highly favored whose mail brings in an occasional carload order. This is not surprising in view of the severe weather which has until very recently prevailed throughout the entire Northwest, almost preventing salesmen from making their regular visits to the towns in their territory. The city trade is light, orders generally calling for one or two stoves or ranges at a time, very rarely running up to half a dozen.

WE ARE INDEBTED to the Round Oak Stove Works, Dowagiac, Mich. for some very handsome photographs of the interior of the Beckwith Memorial Theatre, the completion and dedication of which was referred to in these columns not long since. One view represents the drop curtain, another shows the stage as viewed from the parquette, while a third represents a tier of boxes. Judging from the photographs before us, the interior is very handsomely decorated and conveniently arranged and is a credit to all concerned in its design and construction.

THE O'RORKE STOVE REPAIR COMPANY of Peoria, Ill., have brought out a volume entitled "O'Rorke's Stove Repair Key." It is issued for the purpose of enabling stove dealers to fill orders for repairs for a large number of stoves by means of a very small stock. The work gives a list, it is claimed, of over 5000 stoves which have interchangeable parts or are duplicates, and describes the marks on the various castings so as to enable the dealer to tell what stoves they will fit. The names of the stoves are arranged in alphabetical order down the left hand side of the page, while, after each name, in parenthesis, is an indication of the kind of stove—whether coal or wood, or for heating. Following this in turn are the names of the concerns making stoves which the castings named in the list will fit. We understand that the object of this volume is to facilitate the ordering of repairs on the part of dealers.

KEARNS WROUGHT STEEL RANGE COMPANY of Philadelphia, Pa., have removed their office and show rooms to No. 1020 Arch street, where they will be under the personal charge of John J. Kearns. They also state that they have secured a large factory in Burlington, N. J., and have fitted it up with every modern appliance for the quick production of their goods. These changes have been made necessary by the increase in their business, and the company state that it is the third time in as many years that they have been compelled to seek other quarters owing to lack of room.

JOHN JACOBS, the popular stove and hardware dealer of Little Falls, N. J., while giving Charles E. Coleman of Eugene Munsell & Co., a sleigh ride a few days ago, had the misfortune to get upset in front of the courthouse at Paterson. The sleigh became involved in the electric car tracks in such a way as to throw both gentlemen into the street. Although neither was seriously injured, the mishap caused no little excitement and a crowd soon gathered; even the small boy was there and participated in the fun.

THE WROUGHT IRON RANGE CO., of St. Louis, Mo., and with Canadian works at Toronto Junction, have issued an edition of their catalogue of Home Comfort wrought steel ranges and hotel kitchen outfits, which is considerably smaller in size of page than the one which was reviewed in these columns a week or two since. The matter embodied is practically the same as that contained in the larger catalogue, but the cuts are reduced in size and the text printed in smaller type. The covers are of red paper, and upon the front one is an interior view of a kitchen equipped with one of the company's outfits.

THE RETAIL STOVE TRADE along the Hudson River appears to be pretty well canvassed just at the present time, as may be evidenced from the fact that one day last week the following well known representatives were visiting dealers in that section: A. R. Bond of the Perry Stove Company; T. A. Dreer, of the Reading Stove Works; Charles E. Coleman, of Eugene Munsell & Co.; W. F. Geer, of Rathbone, Sard & Co.; Charles S. Ingham, of the Syracuse Stove Works; G. T. Hedenberg, of Janes & Kirtland, and W. F. Myers, of the Union Stove Works. All these knights of the grip reported a fair demand for the specialties of their several firms.

AT A MEETING of the directors of the Lebanon Stove Company, held at Lebanon, Pa., on the morning of Saturday, February 25, John H. Sultzer, treasurer, resigned, and Harry A. Reinoehl was unanimously elected to fill the vacancy. We understand that Mr. Sultzer has recently purchased the interest of John F. Snavely, of the firm of Sultzer & Snavely, and will devote his time to mercantile interests. The new firm will be known as J. A. Sultzer & Brothers.

THE WROUGHT IRON RANGE COMPANY, St. Louis, Mo., have recently secured a contract from the United States Government for a complete kitchen outfit for Mess Hall at Fort Crook, Neb. The weight of the range is 3 tons. They have also shipped Home Comfort ranges to the following places: Soldiers' Home, Minneapolis, Minn., weight of range, 3½ tons; Pacific Hotel, Jacksonsville, Ill., weight of range, 1 ton; Hotel Rennick, Bement, Ill.; Van Buren College, Van Buren, Maine, weight of range, 1 ton; Arkansas State Insane Asylum, Little Rock, Ark., weight of range, 4 tons; New Hotel Tahlequah, Ind. Ter.; Paxton's Hotel, Omaha, Neb., weight of range, 2½ tons; New Hotel, Taylorville, Ill., weight of range, 1½ tons; "B. & M." Eating Houses, Shreveport, La.; Wooding Camp, Deadwood, Dak.; Longinotti's Hotel, Atlantic City, N. J., weight of range, 1 ton.

A. C. BARSTOW, JR., treasurer of the Barstow Stove Company, made a flying trip through Arkansas last week inspecting a family railroad property with the superintendent of the Cleveland, Canton & Southern Railroad in which road Mr. Barstow is a director and officer. A little time was spent at the Hot Springs, which place is now in the height of season.

AT THE ANNUAL ELECTION of trustees of the Perry Stove Company, Albany, N. Y., the following were chosen: Nathan B. Perry, John T. Perry, George W. Hobbs, Edward R. Perry, A. N. Perry, G. Y. Lansing and A. A. Thompson.

The Commercial Credit Guaranty Company have just been organized by the wholesale merchants of Chicago for the purpose of insuring the commercial credits of the wholesale trade of the United States. On the 6th inst. a meeting was held at the Grand Pacific Hotel in that city for the election of officers and directors. James A. Sexton, of Cribben, Sexton & Co., presided, and the following officers and directors were unanimously elected: Edmund Burke, president; Edward Rose of Strauss, Yondorf & Rose, first vice-president; W. A. Mason of James H. Walker & Co., second vice-president; Aug. Blum, cashier Union National Bank, treasurer; Josiah Cratty, Tacoma Building, secretary; E. K. Sumerwell, general manager; H. Waldman, actuary and superintendent of agencies; S. H. Sweet of Sweet, Demptser & Co.; James A. Sexton, U. S. postmaster, Chicago; David Kelley of Kelley, Maus & Co.; A. D. Kelley of Kelley, Maus & Co.; Charles A. Morrill of C. A. Morrill & Co.; Charles E. Frankenthal of Frankenthal, Freudenthal & Co.; Samuel J. Kline of Jos. Biefield & Co.; Wm. H. Bush of Bush, Simmons & Co.; R. L. Henry of R. L. Henry & Co.; P. C. Maynard of Phelps, Dodge & Palmer Co.

The estimated export of wheat from Argentina in 1891 was five times as large as in 1885, and the area under wheat is believed to be nearly 3,000,000 acres, or nearly one-third of the whole area under cultivation in 1892. The crop prospects for the next season are only fairly good.

TRADE REPORT.

The Iron Market.

Taken as a whole, there is an increased demand for Iron throughout the country, though inside prices rule, and manufacturers have come to the point where some will shut down their works rather than submit to lower prices. With few exceptions orders are placed for immediate delivery, or for delivery covering but two or three months. In some parts of the West contracts have been made which cover shipments for the entire year. While the volume of business is fairly satisfactory the market is weaker, concessions being made by nearly all the districts which contribute to the supply of the territory tributary to New York. In the Eastern market generally the demand would be considered good in ordinary times, but with such a large capacity for production, and with so much delay in specifying, mills are all the time close to the end of their order books. Prices, therefore, are very feverish and in some cases during the past few days have been quoted lower than ever. The feeling is that a line must be drawn somewhere, and that line appears to be at inside quotations. Some leading concerns are refusing to meet the figures named by others, on the ground that business on such terms must inevitably result in loss ; and sooner than do that they will close their mills. The improvement, therefore, is somewhat of a negative character, and is comprised in refusing prices which were recently accepted, rather than on actual business at advanced prices.

The Pig Iron market shows no change from last week, and in all ordinary transactions prices have been well maintained. Anything not strictly first class in point of quality would probably have to be shaded a little, but at prices quoted below there is a market for almost anything that may be offered. The demand is chiefly for standard brands, and these are absolutely firm, but when it comes to an off grade or a large lot which can only be placed in certain quarters more or less dickering is required to get it through. With this exception the market is singularly monotonous; makers do not feel warranted in putting up their prices, and they certainly won't put them down so long as they are as well sold up as they are at present.

The first week in March finds the business situation in the Pittsburgh market more satisfactory than at any time during the two months of the year just closed. Of course there has not been much improvement in prices as yet, but there has been some, and in view of the heavy demand being experienced for some lines of both Finished and Raw Material, it is more than probable that higher prices will prevail on some articles before very long. This applies particularly to Wire Nails and Wire, the demand for both at this time being extremely heavy. This activity is being felt in the Steel market, and Steel for early delivery is in good demand and at satisfactory prices. A heavy increase in orders for Structural Shapes is reported, and makers confidently expect a very busy season. Railroads are commencing to place orders for both car and track equipment, and this will have a favorable effect on business of all kinds. Perhaps the worst feature in connection with the Iron and Steel trades to-day is the difficulty in making prompt collections. Much complaint on this score was heard last month, but with the opening up of spring trade and more favorable weather, we will, no doubt, have an easier money market.

The business interests of the West are now confronted with a possible serious disturbance in the shape of a strike of all the switchmen on the railroads centering at Chicago. The situation is regarded as very grave, because the railroad managers insist that they are not able to comply with the switchmen's demands for considerably higher wages. If the strike really takes place it promises to be the most serious with which the railroads have yet had to contend. Merchants and managers advise their customers to order goods promptly so as to get them out before railroad operations are completely suspended.

All branches of the foundry trade are participating in the demand, which is better than was known at the same time last year. The Architectural Iron workers report their trade more promising than for a long time, as they are now able to compete with the Steel manufacturers in making prices on Column work. Good contracts have been placed lately for Southern Coke Iron, but in almost every case at prices below our recent quotations. Representatives of strong Southern companies claim to be getting more for their Iron than small manufacturers, as consumers are somewhat apprehensive that they will not be able to get full deliveries from the latter on contracts covering shipments extending well into the future. Rumors are current of prices made for Southern Iron during the past day or two at lower rates than anything previously known in this market.

There has been a fairly satisfactory volume of distribution of Pig Iron during the week, although it was mainly in small lots, there being no disposition on the part of buyers to contract for large quantities for forward delivery; the largest sale made being 3500 tons for March, April, May and June delivery on the basis of prices current for spot delivery, and in almost every instance the sales have been made at the inside quotations. During the last few days there has been a more active inquiry for Pig in anticipation of the wants of consumers, which may result in a large volume of business. Iron is cheap enough; prices are as low as it is reasonable to expect them to be, but at the moment there appears to be no advantage in buying far in advance of current consumption. There have recently been liberal purchases of Soft Southern Iron, which is wanted for mixing with the harder Northern Irons, and No. 1 and No. 2 Soft Foundry Coke Irons have been pretty well sold up and they are becoming scarce.

In the New York market the Thomas Iron Company report having booked quite a number of orders from old customers under the usual conditions. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14 25 @ $14.75 for No. 1; $13.25 @ $13.75 for No. 2 and No. 1 Soft.

In the Philadelphia market low-grade Irons are wanted at about 25¢ less than quoted rates, but as no one seems inclined to meet bids of this character. Makers claim that there is no money in the business at present prices, but there is nothing in sight to warrant predictions of anything better in the immediate future. On the other hand, solvent concerns are determined to go out of the business rather than to submit to lower figures, so that even if prices do not improve there is hardly a possibility of them working to a lower point. General quotations as follows for Philadelphia and equivalent deliveries, with 25¢ to 50¢ less on Southern brands at Harrisburg and Intermediately to Baltimore:

American Scotch, No. 1X.....	$17.00	@ $17.25
American Scotch, No. 2X.....	16.00	@ 16.25

At Chicago a very fair movement has taken place in local Coke Iron, but not so large as in the previous week. Plenty of business is reported to be still in sight. Buyers are coming in who were not expected to make their appearance at this time of the year. The disposition to purchase for long deliveries is still prominent and recent contracts have been made which cover shipments for the whole of this year. The consumption is unexpectedly active, as very heavy shipments are going forward now. Lake Superior Charcoal is still quiet. We revise our quotations as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50 @	$17.00
Local Coke Foundry, No. 1	13.25 @	13.75
Local Coke Foundry, No. 2	13.00 @	13.25
Local Coke Foundry, No. 3	12.75 @	13.00

It is reported from Southern markets that some of the Southern furnaces sold more Iron than they produced during the month of February and consequently reduced their stocks, and the indications are that this was the general experience. The feeling in the trade is rather better than a week ago, but there is no change to be made in quotations.

Foundry.

Southern Coke, No. 1	$13.25 @	$13.50
Southern Coke, No. 2	12.00 @	12.25
Southern Coke, No. 3	11.25 @	11.50
Ohio Soft Stone Coal, No. 1	16.00 @	16.25
Ohio Soft Stone Coal, No. 2	15.00 @	15.25
Mahoning and Shenango Valley	14.75 @	15.00
Hanging Rock Charcoal, No. 1	19.00 @	19.25
Hanging Rock Charcoal, No. 2	18.00 @	18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @	15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @	14.75

Metal Market.

Pig Tin.—Between a blunder of the Washington representative of the United Press regarding the fate of the bill to prevent the duty prescribed in the McKinley tariff law going into effect on July 1, and effective manipulation of prices by some prominent operators upon evidence that there really had been a serious mistake on the part of the news gatherers, the market has been enlivened considerably. When the announcement was made that the bill to abrogate the proposed duty had become a law prices drooped wearily, and there were apparent anxious sellers at 20¼¢ ℔ lb for any delivery up to and including July. Immediately upon the circulation of rumors, well supported, that the report was erroneous the complexion of affairs underwent a decided change. Instead of sellers at the price named, buyers at 20¼¢ came prominently to the front, but Tin did not. Subsequently the bull interest made the most of every circumstance in their favor and raised quotations to 20.80¢ @ 20.90¢, without actually buying enough Tin to inspire outside confidence in the apparent strength of the market. After the advance was established some few trades were put through, but the greater portion of the transactions were between a few operators who have everything to gain and nothing to lose by keeping quotations high. It is no secret that spot stocks are heavy, including a considerable "invisible" supply, and that about 2000 tons are due here this month. Some authorities state also that consumers are well stocked and unlikely to figure as heavy or anxious buyers in the immediate future, leaving the task of maintaining prices chiefly upon the sholders of the leading speculators. The short interest on this side of the Atlantic is comparatively small, but the reverse is believed to be the case in London.

Copper.—No large dealings or anything more than very commonplace run of orders are reported here as yet, but the statement comes from a reliable source that the spot supply of C. & H. brand has been worked down so closely that it was necessary to make some overland shipments to the works in order to fill contracts, and a few of the smaller producers, it is also learned, are almost bare of spot stock. No considerable quantities are available just now at less than 12¢ for Lake Superior Ingot and 11¢ for common casting brands.

Pig Lead.—During the early portion of the week under review about 300 tons Common were sold at 3.85¢, near future delivery. Subsequently single carloads realized 3⅞¢ @ 3.90¢ and toward the close the latter price was paid for larger lots to the extent of about 150 tons all told. At this writing the demand is rather slow, but reserved offering serves to impart some firmness to the market, temporarily at least.

Spelter.—Fair quantities of Western have been sold at 4½¢, delivered in Pittsburgh, and some business for Eastern account was put through early in the week at 4.22½¢ @ 4½¢, delivered, for May and later shipment. For the presept, 4.27½¢ is named as being a close price for round lots, future shipments, while 4.30¢ is generally asked. Spot parcels are held at about the usual premium.

Antimony.—Business has been moderate, but owing to tardiness of arrivals of some brands prices have ruled irregular. Current quotations are 10½¢ @ 10¾¢ for Hallett's, 10¼¢ @ 10½¢ for LX and 10⅝¢ @ 10¾¢ for Cookson's.

Tin Plate.—Fair orders, chiefly for lots of 500 to 1500 boxes of Cokes per month for delivery between May and August, have been placed, but interest in futures is still rather tame, there being no special incentive for anticipating future wants to any unusual extent. Spot business has continued on strictly conservative lines, and of barely fair average volume for the season. Prices remain almost stationary, and the market is steady although quiet.

Coal.

The Anthracite Coal market is steady under a steady demand and is supposed to be unaffected by the disintegration of the combine. The situation, it is claimed, is altogether normal, being governed by the law of supply and demand. No sales are heard of below the old combine schedule, though there has been some talk about cutting. All sizes are plenty, except Pea and Buckwheat, which are scarce, as usual whenever transportation is active. This is explained by the fact that freight charges on these sizes are 25¢ and 40¢ respectively less from the mines to tidewater than the prepared sizes and therefore the latter have a precedence on the railroads. Besides it is not unusual for the small Coal to become congealed in the cars, making it necessary to mine a second time in unloading. Pea, f.o.b., is $2.75 @ $2.85; Buckwheat, $2 @ $2.15. Production for the week, 516,500 tons, a decrease of 215,000 compared with the same week last year, and for the year the decrease is 85,500 tons.

A British syndicate has acquired possession of the Nicaragua State railways and lake steamer system.

Financial.

Now that a new administration is at the helm of public affairs, the financial necessities of the Treasury at once engage attention, as the foreign demand for gold continues, also the issue of notes in purchase of silver bullion, and special provision for the future becomes a peremptory need. The President's inaugural, while recognizing this fact, contains no intimation of the measures of relief to be adopted. It is understood, however, that negotiations are pending with a London firm which provide for a liberal supply of gold in exchange for bonds. Receipts for customs duties being at the present time less than 6 % in gold certificates as compared with more than 80 % two or three years ago, that source of supply can no longer be depended on. The probability of an extra session of Congress to consider the silver question is a subject of discussion, without any decided bias of opinion. For the first time during the current fiscal year the revenues of the Government show a slight decline as compared with a year ago. The receipts for February from all sources are reported as $30,009,000, compared with $30,755,000 for February, 1892. The national bank note circulation increased during February $1,032,235, making the total circulation of this class of money $175,320,356 on March 1.

The stock market was less active, showing the effects of the extreme depression that has overtaken several specialties since the break in Reading, which touched the lowest point since 1891, while Lehigh Valley declined from 121 to 93. The general disposition was to await events at Washington.

Money has been much firmer, influenced by the announcement of intended specie shipments and by the withdrawal of funds by Western banks. The bank statement, as was expected, showed a heavy loss in legal tenders in consequence of the outflow of currency to the interior. The decrease in cash was $5,557,600, and as the loans were contracted to about the same extent, the liquidation in deposit liabilities amounts to $10,703,800. The banks now hold $6,503,125 in excess of the 25 % legal requirement, against $21,292,225 a year ago and $10,880,975 in 1891. As the week closed the loan market was very strong, influenced by the poor bank statement and continued shipments of currency to the interior. Time loans were in active request at 6 %, and borrowers discriminated carefully in the acceptance of collateral. Commercial paper was very slow, and practically without a market. In Boston money loaned as high as 10 %, exciting severe criticism against the banks, but in Philadelphia money was quoted 5½ % @ 6 %. The Chicago market at the end of February was on a parity with New York.

The Prince of Wales has consented to preside at the jubilee banquet of the Iron, Hardware and Metal Trades' Pension Society of Great Britain, which is to be held this year in London.

Chicago Report.

Scrap.—Iron and Steel scrap are extremely dull again, and prices are weak. Dealers quote the following nominal buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	..
Malleable Cast	7.00	...
Stove Plate (free of burnt)	7.00	...
Burnt Iron and Grate Bars	5.00	...
Sheet Iron and Hoops	4.00	..
Plow Steel and Breaking Stock	8.50	...
No. 2, such as Shovels, Hoes, &c.	4.50	...
Old Boilers—whole (Iron)	8.00	...
" (Iron)—cut in single Sheets and Rings	12 00	...
Old Gas-Pipe and Boiler Tubes	9.00	..
Cast Borings	5.00	....
Turnings	6.00	..
Horseshoes	13.00	..
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—Quotations are steady at the following rates on carload lots of 12 net tons:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10

A correspondent of the *Indian Engineer* says: "Crushed steel is fast coming into use for cutting stone. It appears to be made by quenching very high carbon steel in cold water, from an excessively high temperature, such as would overheat steel for most purposes. This renders it not only hard, but rather brittle, so that it is possible to pulverize it. It is crushed in a stamp mill, and sifted closely to size. It is said to be not only cheaper, but much more effective than emery, giving a better polish and quicker, and lasting much longer."

The pneumatic dispatch system of the Electric Pneumatic Transit Company was tested at Philadelphia last month. A double line of 6-inch pipe has been laid on Chestnut street from the post-office building at Ninth street to the sub station between Third and Fourth streets, a distance of 2835 feet. Postmaster General Wanamaker sent the first package over the line at 4.18 p.m., a Bible wrapped in an American flag. The pipe is ordinary wrought-iron pipe bored smooth. The carriers used are of steel and carry about 15 pounds weight. The air pressure used is 6 pounds per square inch, and the speed of transmission in the tests was 45 to 49 feet per second—30½ to 34 miles per hour. The plant will be operated for a year by the company free of expense to the Government; at the end of that time the Government will have an option for the purchase of the system.

CONDITION OF THE

Hardware Trade.

MARCH BUSINESS thus far, although good, has not shown as much increase in volume over the latter part of February as was expected. While the demand is good and probably up to the average, purchases are not made as freely or in as large quantities as was hoped. The prevalence of severe weather in the Northwest has had a good deal to do with holding back trade in that important section, but with the opening of spring it is expected that there will be a general quickening in trade. There is also some unevenness in business, some manufacturers reporting a heavy and very satisfactory trade, while others refer to the demand as only fair. In heavy goods there appears to be a better business doing than in Shelf Hardware, and some of the manufacturers find it difficult to supply the goods as fast as required. Prices continue without important change with a maintenance of the improved feeling in some lines. Collections are fairly good, but in some cases complaint is made of sluggishness.

Advices from Chicago.—March has not realized the expectations of Shelf Hardware jobbers in the volume of business. Last week was exceedingly wintery throughout the whole Northwest, checking trade in every direction. Orders are better this week, which has opened in a way to encourage merchants in the belief that business will be large as soon as something like spring weather prevails throughout the agricultural sections. The heavy Hardware trade, on the other hand, is very much better than it has been, owing to the increasing demand from all classes of manufacturing consumers. Collections are still below the average and considerable complaint is heard of the scarcity of money. The remarks previously made with regard to the holding of grain stocks by farmers have covered this ground, but it is expected that as soon as spring opens and the grain in the lake harbors as well as in farmers' hands can be forwarded to Eastern markets, the situation will be very greatly improved in this respect.

Notes on Prices.

Cut Nails.—The condition of the Cut Nail market is substantially the same as last week. It is characterized by an improved tone and a good demand, with the promise of a heavy trade during the season. The mills are quoting almost universally on the basis of the Wire Nail card recently adopted by them, their price being in the East $1 25 base for carload lots at mill, and, while this price is fairly well maintained, it is sometimes shaded a little. The quotation for carload lots in New York is $1.40. The modifications in the extras on Clinch Nails made by the Eastern manufacturers at their Philadelphia meeting have not yet been adopted by the Western mills, and it is doubtful whether they will be, so that in this respect there is a slight difference in the cards used in the East and West. While this difference will cause but slight inconvenience, it would be more satisfactory if but one card applied to the whole country. Some criticism is expressed because under the Nail card now in use the matter of averages is considered in making quotations, even though it may not be explicitly referred to, inasmuch as manufacturers of both Wire and Cut Nails expect that orders will have about a 50-cent average, and decline to sell large Nails alone at the price of an assorted order. The adoption of the same card for both kinds of Naila is, however, an important step in advance and does a good deal to simplify the purchase of Nails. It would be a matter for congratulation, however, if the card were so graded as to obviate the necessity of coosideriog the question of averages. In order to do this it would be necessary for the Nails to have extras which would correspond to their cost, so that it would be a matter of indifference to the manufacturer what kinds or sizes were purchased. So long as the card is unequally graded, as at present, the question of averages will, however, have to be considered. For the convenience of the trade we give below the Nail card now in use, showing the difference on Clinch Naila as maintained by the Eastern and Western manufacturers:

National Cut Nail Schedule.

Adopted Feb. 15, '93.
Revised Feb. 21, '93.

Common, Fence, Brads and Sheathing.

	Advance.
60d	Base
50d	$0.10

8d	.70
6d and 7d	.85
4d and 5d	1.00

Each half keg 10 cents extra.

Advices from Chicago.—The Wheeling makers of Steel Cut Naila are now having a decided revival of trade in the district from the Mississippi River west, which they are able to reach in competition with Chicago manufacturers. The new Nail card, they claim, is being strictly adhered to, and quotations are not being made on the base of an average. It is asserted, however, by jobbers that special prices are being quoted on orders covering particular sizes on which the average is high. It

is evident that the trade in Cut Nails is now better than for some time past, but it remains to be seen whether this is a gain on the Wire Nail trade or whether it is merely an incident of the unusually heavy spring demand for building material. Manufacturers' quotations are still $1.42½ for mill shipment, Chicago delivery. Jobbers are selling at $1.50 from stock on the new card.

Wire Nails.—The Wire-Nail market is in excellent condition and the recently advanced prices are regularly maintained. Notwithstanding the successive advances business continues good, and the mills are booking a good many orders and have many inquiries. The fact that most of the large jobbers have heavy stocks on hand purchased at the extremely low prices which ruled a few weeks ago is referred to as likely to interfere somewhat with the demand on the manufacturers, as the jobbers are in a position to meet if not undersell factory quotations. The present quotation is $1.50 for carload lots at mill, Pittsburgh being the point of equalization for the East and Cleveland for the West.

Advices from Chicago —Manufacturers of Nails report a quiet condition of trade. The advanced price has checked new business. Factories are well sold up, however, the largest of them reporting their full capacity engaged for the months of March and April. The regular quotation now from factory is $1.65, Chicago. This is the same price made on carload lots by jobbers, who are also quoting $1.70 for small lots. The jobbers report a good business, which only needs a few days of fine weather to develop into large proportions.

Barb Wire.—The market is characterized by an excellent tone, and prices are somewhat stronger, though there is no quotable advance. For carload lots at mill $2.40 to $2 45 representa the market, but some of the manufacturers are asking higher figures. Small lots of Galvanized Four Point from store in New York are regularly held at $3.10, an abatement of 10 cents per 100 pounds being made in carloads.

Advices from Chicago.—The demand is very good and prices are stiffening both from manufacturers' and jobbers' hands. Manufacturers report more trouble in securing cars with which to make shipments than in getting orders. They continue to quote $2.20 for Painted from factory and $2.60 for Galvanized. Jobbers are selling small lots at $2.25 and $2.65, respectively.

Cordage.—The National Cordage Company have withdrawn quotations and prices are named on application. Notwithstanding this fact the market, in the matter of price, is in substantially the same condition as for some time, except that perhaps Sisal is a shade higher. The competition between the combination and the outside manufacturers continues very animated and prices are somewhat uneven.

Carriage Bolts.—The market for Common Carriage Bolts being an open one low prices are ruling, and some of the manufacturers within a few weeks have been making concessions on quotations which had formerly prevailed. Other manufacturers are, however, maintaining prices more firmly and refusing to meet the quotations of their competitors.

Vassar Cylinder Night Latch.—This article, manufactured by the Reading Hardware Company, Reading, Pa., and 81 Reade street, New York, is quoted to the large retail trade at $13.50 per dozen.

Brass Kettles.—The line of Improved Brass Kettles, made by the Lalance & Grosjean Mfg. Co., 19 Cliff street, New York, are quoted at 21 cents per pound on all sizes from 7 to 20 inches, inclusive, f.o.b. New York, 60 days, or 2 per cent. discount for cash in ten days. The following table gives the sizes, weight and capacity of these goods:

Inches.....	7	8	9	10	11	12	13
Pounds.....	1¼	1½	1⅞	2	2¾	4	4½
Gallons....	¾	1	1¼	1½	2	2½	3
Inches.....	15	16	17	18	19	20	
Pounds.....	6	7	8	10¼	11¼	14¼	
Gallons....	5	6	8	10	12	14	

Enameled Iron Ware.—Under date of March 4, Manning, Bowman & Co., New York, issue a circular letter to the trade, in which they state their purpose to continue protection to the jobbing trade in their margin on Enameled Iron Ware, if they will hold fast to the agreed prices. The manufacturers state that this season opened with a slight cutting of prices by some jobbers, and as they have done their utmost for the maintenance of the established price, they have no other resource but to decline the orders of any jobber who may further violate the agreed discount of 25 per cent., 2 per cent. discount for cash. They further state that they shall do this without distinction or favor, regardless as to where it strikes. This letter is accompanied by a circular devoted to Perfection Granite Iron Ware and Decorated Pearl Agate Ware, containing information useful for traveling salesmen of jobbers who carry the goods, in properly representing the goods to customers.

The Henn Can Opener.—The following are the prices of the Henn Can Openers, manufactured by A. S. Henn & Co., New Haven, Conn.:

No.
60, imitation ebony handle, nickel plated, per dozen.....$1.50
60, imitation ebony handle, nickel plated, per gross.....15.00
65, enameled handle, polished, per dozen.. 1.25
65, " " " " gross..12.00

Prize Cartridges and Shells.—Peters Cartridge Company, Cincinnati, Ohio, for whom J. C. McCarty & Co., are agents, 97 Chambers street, New York, issue under date March 1 a revised price-list showing some additions to their line. Several numbers have been added to the Prize Cartridges since last season and Smokeless S. S. Cartridges, loaded with London S. S. Powder, in any size Shot, have recently been put on the market. The list of the latter is as follows, subject to a discount of 40 per cent.:

Smokeless "S. S." Cartridges.

12 Gauge.			Per 1000.
2½ Drams (measure)	1⅛	ounce.....	$35.00
2¾ " "	1⅛	"	36.25
3 " "	1⅛	"	37.50
10 Gauge.			
3½ Drams (measure)	1⅛	"	39.75
3⅝ " "	1¼	"	42.00
3¾ " "	1¼	"	43.25

Wolverine Hog Rings and Ringers.—Heesen Bros. & Co., Tecumseh, Mich., announce the following reduced prices to the retail trade on the above goods:

New or Old Style Ringers....$1.25 per dozen.
Hog or Pig Rings.....$2.50 per 1200 Rings.

Leggett's Liquid White Glue.—Leggett & Bro., 301 Pearl street, New York, are selling their Liquid White Glue at the following list prices, which are subject to a discount of 20 per cent.:

In Bottles, New Style, with Brush attached.

	Per gross.
1-ounce or small, 1 dozen in box, gross cases.....	$12.00
½-gill or 2-ounce, 1 dozen in box, gross case.....	18.00

In Tin Cans, New Style, with Brush attached.

	Per dozen.
Gill or 4-ounce, 1 dozen in box, 6 dozen in case.....	$2.00
½-pint cans, 2 dozen in case.....	3.00
Pint cans.....	4.50

In Round Tin Cans with Patent Double Cover.

	Per dozen.
Quarts, 1 dozen in case.....	$7.00
½-gallon, ½ dozen in case.....	12.00
Gallons, ½ dozen in case.....	20.00

Assortment A contains

	Per dozen.	
2 dozen 1-ounce or small bottles, at.....	$1.00	$3.50
1 dozen 2-ounce or ½-gill bottles, at.....	1.50	

Assortment B contains

	Per dozen.	
2 dozen 1-ounce or small size, at.....	$1.00	$7.00
1 dozen 2-ounce or ½-gill, at..	1.50	
1 dozen 4-ounce or gill, at ...	2.00	
½ dozen ½ pints, at.....	3.00	

A wire show stand is packed in each assorted case without charge.

Acme Dinner Pails.—The Acme Dinner Pail, manufactured by the Acme Stamping Company, East Stroudsburg, Pa., is sold to the trade at the following prices, which are subject to 2 per cent. discount for cash in ten days, terms, f.o.b. cars East Stroudsburg:

	Per dozen.
No. 1.....	$3.50
No. 2.....	4.00
No. 3.....	5.00

Special prices are made on orders of 1 gross or more.

Forhan's Improved Star Blind Tenons.—These goods are put on the market by Braunsdorf & Gerstner, 634 Eighth avenue, New York, and are sold to the trade at from 70 to 75 cents per gross.

Home Nails.—Atlas Tack Corporation, Boston, Mass., are now putting on the market their Home Nails. They are sold at the following prices, which are subject to a discount of 50 per cent.:

No. 200.....	per carton,	$2.50
No. 200.....	per case,	30.00
No. 400.....	per carton,	5.00
No. 400.....	per case,	60.00

Their Home Tacks, similarly packed, are sold at the following prices, subject to a discount of 50 per cent.:

No. 50.....	per carton,	$3.00
No. 50.....	per case,	36.00
No. 100.....	per carton,	6.00
No. 100.....	per case,	72.00

It is stated that orders will not be accepted for less than one case of 12 cartons.

Automatic Fishing Line Float.—The Horton Mfg. Company, Bristol, Conn.,

quote their Automatic Float at $12 per gross.

Aluminum Cooking Utensils.—The Illinois Pure Aluminum Company, Lémont, Ill., have recently added to their line of Aluminum Cooking Utensils 12 inch Fry Pans, which are sold at $15 per dozen, and 13 inch Wash Bowls, which are sold at $9.60 per dozen, these prices being net 30 days, or 5 per cent. for cash on receipt of invoice.

Eaves-Trough Hangers.—The prices given below apply to Eaves-Trough Hangers manufactured by Henry B. Todd, Meriden, Conn. The Boss Hanger is a new form of the Yankee Hanger, made under the same patent. They are non-adjustable, made of soft steel, and are designed to meet the demand for a strong, convenient and cheap Hanger. Prices on Hangers are as follows, subject to a discount of 2 per cent. for cash in 10 days:

Eaves-Trough Hangers—Yankee Adjustable.

	Per gro.
3 inch cross bars	$5.50
3½ " " "	5.50
4 " " "	6.00
4½ " " "	6.00
5 " " "	6.50
5½ " " "	6.50
6 " " "	9.50
7 " " "	12.50

The Boss.

Straps riveted on cross bars complete.

	Per gro.
3 inch	$3.50
3½ "	3.50
4 "	3.75
4½ "	3.85
5 "	4.00

Wrought-Iron Pipe.—The market in Wrought-Iron Pipe continues weak and demoralized, and being an open one manufacturers are free to make such figures as they choose. The following revised quotations have recently been issued by the Nason Mfg. Co., 71 Beekman street, New York:

	Per cent.
Plain, 1¼ inch and smaller sizes	60 and 10
" 1⅜ " " larger "	70 and 10
Galvanized, 1¼ inch and smaller sizes	52½ and 10
Galvanized, 1⅜ inch and larger sizes	60 and 10

Extra and Double Extra Strong.

Plain, 1¼ inch and smaller sizes	60
" 1⅜ " " larger "	70

Glass.—Quietness continues to be the prevailing feature of the Glass market, both in the city and with out of town trade. The prospects of mild weather, which would give employment to the building trades, were changed by snow and storm, and until settled weather is assured Glass will be in small demand. National Window Glass prices are being adhered to by members of the association, while jobbers who are not members are quoting somewhat lower prices, equivalent to 2½ to 5 per cent. Imported Glass has not recovered any of its lost ground and is being sold from 75 and 10 and 5 to 80 and 5 per cent discount. In Plate Glass the situation is unchanged, there being almost no demand. Quotations remain as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Trade Notes.

THE MILWAUKEE GAS STOVE COMPANY, of Milwaukee, Wis., in an announcement elsewhere direct attention to the Perfection gas heating stoves and ranges, with or without water backs. They also refer to a long line of special Heaters for particular purposes.

IN A PROMINENT ANNOUNCEMENT in our advertising columns this week the Kanneberg Roofing Company, Canton, Ohio, make reference to a patent granted February 28 to Albert Kanneberg for an improvement in sheet metal roofs. The trade will be interested in this announcement, as well as in the reference to the increased capacity of the works of the Kanneberg Roofing Company.

J. M. & L. A. OSBORNE, Cleveland, Ohio, direct attention in our advertising columns this week to tin plate and sheet iron which they handle.

WE UNDERSTAND that the Stark Machine & Tool Company, Buffalo, N. Y., are meeting with an increasing demand for tinner's machines and tools. During the past week they have booked orders for 12 outfits, and they have to run their shop 90 hours per week to keep up with the orders.

THE JOSEPH DIXON CRUCIBLE COMPANY have been awarded a space of 25 x 28 feet in the Mines Building of the Columbian exposition for a general exhibit of Graphite productions, such as Crucibles, Lubricating Graphite, Graphite Axle Grease, Plumbago Facings, Graphite Machine and Railway Grease, Dixon's Stove Polish, Silica Graphite Paint, Core Wash, Electrotyping Graphite, Graphite Cylinder Oil, Graphite Specialties for electrical and other work, &c. A space of 13 x 10 was obtained in the Manufacturers Building for an exhibit of Dixon's American Graphite Pencils and Pencil Sundries. Although the assignment of space has been tardy, and the amount much less than required, and not much time left to properly equip it, yet the company propose to be there on time and in good shape as possible.

CURTIS & CURTIS, Bridgeport, Conn., send a copy of a decision rendered by Judge Ricks, June 20, 1892, in the Circuit Court of the United States for the Northern District of Ohio, Western Division, in the city of Toledo. The decision is in the case of Curtis & Curtis *vs.* Willet C. Wells, and is for the plaintiffs. The decision holds that the patents issued to William D. Forbes, No. 253,996, for an improvement in pipe threading machines and assigned to Curtis & Curtis, likewise patent 277,256, are good and valid and that the defendant had infringed upon these patents. The plaintiffs are awarded damages and a perpetual injunction is issued restraining the defendant from continuing to make any machines about which suit was brought. In a note to this decision Messrs. Curtis & Curtis state that Willet C. Wells has transferred his business to the Merrill Mfg. Company, who are continuing the manufacture of pipe threading machines. They warn all persons against purchasing these machines as being liable to damages.

THE WASHBURN & MOEN MFG. COMPANY announce that George A. Cragin, heretofore agent at San Francisco, has been requested to take charge of their interests in the State of Texas, with office at Houston. Mr. Cragin will be succeeded by Frank L. Brown, who has been appointed their Pacific Coast agent and will be in charge of their office and warehouse at 8 and 10 Pine street, San Francisco. Mr. Brown was for a number of years the secretary of Staver & Walker, and more recently of Mitchell, Lewis & Staver Company of Portland, Ore., and is, therefore, familiar with the trade on the Pacific Coast.

AMONG the enterprising salesmen one meets in Vermont are Charles Gallagher, with S. G. Davis & Co., Tin Ware, Boston, who has traveled his territory for a number of years, and long ago wore the edge off of that old chestnut, "Let her go;" and E. P. Fiske of J. H. Cunningham & Co., Boston, who is modest and retiring until Wrought-Iron Pipe and Fittings are mentioned.

A. B. KINGSLAND & Co., Burlington, Vt., have recently been allowed patents on an improved Portable Baking Oven. This Oven is constructed on a new principle and is described as great improvement over the old-style bakers. They are especially adapted for use in hotels, restaurants and bakeries.

AMONG recently authorized corporations in Illinois are the following: The American Smoke Preventer Company at Chicago; capital stock, $150,000; for the manufacture of smoke preventers; incorporators, William R. Mills, Charles Smith and Weston O. Knowles. The International

Automatic Air-Brake Coupler Company at East St. Louis; capital stock, $10,000,000; for the manufacture of automatic air-brake couplers and connections of air for railroad cars and other vehicles; incorporators, William R. Harris, John H. Wear and Lewis Bieman. The Marion County Rapid Transit Company at Centralia: capital stock, $75,000; to build and operate an electric railway and to furnish light, heat and power; incorporators, S. N. Pierce, O. V. Parkerson, C. B. Ellis, L. Sonnerville, John F. Sugg, S. J. Smith and J. D. Telford. The Watson Down Draft Furnace Company, at Chicago; capital stock, $100,000; for the manufacture of furnaces; incorporators, Edwin J. Noble, George F. Westover and M. W. Geisinger. The Indurated Fiber Ware Company at Chicago; capital stock, $10,000; for the manufacture of merchandise and to conduct a commission business; incorporators, George H. Best, Lowther Ferris and Harry T. Lockwood. The American Change and Register Company, at Chicago; capital stock, $40,000; for the manufacture of cash registering machines; incorporators, Charles E. Braden, George E. Hopkins and John G. Elliott. The Illinois Refrigerator Company, at Chicago; for the manufacture of refrigerators and wooden ware; incorporators, J. B. Markey, E. A. Smith and J. F. Hanehan. The Royal Columbia Heat Radiator & Automatic Lamp Filler Company, Chicago; capital stock, $2,000; incorporators, Ambrose A. McKey, James P. Hoselton and Alexander N. Murray. Post Metal Company, at Chicago; capital stock, $50,000; for the manufacture of metal specialties and to conduct a general transportation business; incorporators, Henry C. R. Post, Hugh L. Burnham and Oscar T. Lindrooth. The Coal-Saving Grate Company, at Chicago; capital stock, $50,000; for the manufacture of grates; incorporators, Henry Peterson, Carl H. Leopold and J. H. Kraft. The Ramsey Self-Lock & Nut Mfg. Company, at Ramsey; capital stock, $10,000; incorporators, H. E. Lantz, S. L. Neeley, George W. Nichols, J. L. Furneaur.

A. J. WEED & Co. of 106 Liberty street, New York, are now building a Vertical Marine Engine in three sizes—½, 1 and 2 horse-power. These engines are especially designed for those amateurs desire to build their own engines, or such parts of them as their facilities will allow. With that end in view the castings are to be had, not only in the rough, but also in various stages of completion. In one set all parts for which the planer is necessary are machined, thus giving the amateur who has only his lathe his castings ready prepared. In another set the cylinder and steam chest are bored and faced, the guide is bored, and, in general, the more difficult lathe work is done. In another set, in addition to that which is completed in the other sets, the bearings are babbitted, eccentric straps bored, and eccentrics, piston, cross head, slide valve and fly wheels are turned. As will be seen, this allows a selection of the parts in such stage of completion as will best suit the facilities of the builder. The engine is well designed and proportioned in every respect.

THE WESTERN TINWARE MFG. COMPANY of Omaha, Neb., are doing a successful business, and are giving employment to 35 men in the factory and keep six travelers on the road. The factory and offices are lighted by electricity, and the works are kept running the year round from seven in the morning till six in the evening.

THE PORTLAND TINWARE COMPANY is the name of the corporation which has succeeded F. E. Briggs, of Deering Center, that State. The plant of Mr. Briggs was removed to Portland and a stock company formed with a capital of $50,000. The new concern will carry on the business of manufacturing Tinware and Sheet Metal Goods, the same as was done by Mr. Briggs, but on a very much larger scale, and will supply their goods at wholesale only. L. W. Bradstreet is president and F. E. Briggs treasurer.

SWANN, WHITEHEAD & CLARK, lately incorporated in the new concern called the American Lamp & Brass Company, announce their sample room now at 96 Church street will be abandoned May 1, and the goods in future shown at 43-45 College place, now occupied by the Clark Bros. Lamp, Brass & Copper Company, another of the three interests absorbed in the late consolidation. The quarters in College place will be enlarged by the taking in of a portion of the building at No. 45, which will be remodeled so as to have twice the floor space now used. The partition wall between the two buildings will be broken through and a large salesroom provided.

WE ARE ADVISED that Wm. J. Lloyd Mfg. Company, Philadelphia, have discontinued the manufacture of the Great American Meat Cutter and that everything pertaining thereto has been purchased by the Enterprise Mfg. Company of Pennsylvania.

AT A MEETING of the stockholders of the Youngstown Stamping Company, whose affairs were recently placed in the hands of W. C. Hine, receiver, held at Youngstown last week, the following statement of the condition of the concern was presented:

Assets.

Merchandise	$32,131.35
Machinery	13,414.97
Fixtures	2,857.05
Real estate and buildings	22,000.00
Ledger accounts	10,499.13
Total	$80,892.50

Liabilities.

Bills payable	$90,750.00
Acceptances	9,025.80
Ledger accounts	9,035.86
Pay roll	2,170.13
Total	$110,981.79

It is stated that the above figures were made up on the basis of actual values, and when anything of a questionable value came up it was not included. A committee was appointed to confer with the creditors of the concern and endeavor to devise some plan satisfactory to them by which the works can continue in operation.

THE LUDLOW-SAYLOR WIRE COMPANY, St. Louis, Mo., report a large trade in their jobbing department, and have a number of good orders on hand for Ornamental Brass, Iron and Aluminum work. Among those recently secured is one for the grille work for handsome screens to be placed in the rooms of the Noon Day Club of St. Louis.

THE NUBIAN IRON ENAMEL COMPANY of Cragin, Ill., whose main warehouse (250 x 50 feet, two stories) was entirely destroyed by fire February 17, are again manufacturing to their fullest capacity. Before the fire had been extinguished Manager Bonnell was telegraphing for supplies and arranging for the continuance of business. Materials have been contracted for and two buildings instead of one are now under process of construction. The company will, of course, suffer some inconvenience for 60 to 90 days, but they will do their best to satisfy their customers.

THE DUBUQUE STAMPING & ENAMELING WORKS will commence active operations about April 1.

BERNHARD STADELMAN, Pittsburgh, Pa., are manufacturing the Keystone Coffee Jar. The vessel is made of flint glass, with a nickel-plated cork-lined cap, designed to keep liquids carried in the Jar free from rust or acid. The keystone shape of the Jar is referred to as adapting it to oval or square dinner pails and baskets, and the glass of which it is made as preserving the natural flavor of the liquid as long as desired, besides being always sweet and clean. The Jar is made in pint and quart sizes.

THE STANDARD STEEL WIRE MAT COMPANY, recently organized, of New Castle, Pa., have leased the plant of the old Cunningham foundry, which is said to be well located and a substantial building. The concern are now having their machinery erected and are fitting up the plant and will commence operations at an early date.

Spring Fogs.

The last week has brought with it some weather which in any reasonable climate would indicate that winter is broken. The conditions are likely to be favorable for the prevalence of fogs. Fogs characterize a state of the atmosphere peculiarly favorable to the spread of certain diseases, and over land surface are in general a depressing influence upon the human constitution. Far out at sea a fog has quite a different character from fogs found near cities or near malarial districts, because the latter always hold, suspended in the air, particles of dust, smoke and soot from chimneys, dust floating in the air, gases emanating from foul sources, and effluviæ from lungs of human beings and animals, all of which the finely divided water suspended in the air is especially fitted to rapidly absorb and hold near the earth's surface. Here they are breathed in over and over again, very much as exhaled impurities are breathed over and over again in a crowded but very ill-ventilated room. Prof. G. V. Poore stated in a lecture delivered at University College in 1892 that during the great fog in London that occurred on Christmas of 1891, and spread like a pall over that city for five days, the death rate was increased by 1442 deaths, according to returns made January 2, 1892.

Ventilation and Sanitary Plumbing

The arts of ventilation and of sanitary plumbing are so intimately related to atmospheric conditions that any facts concerning these conditions, like those stated in the previous paragraph, should be studied as possibly affording information valuable when practically applied to these arts. A practical lesson that may be drawn from what has been written is, that while air supplied for ventilation should not be so dry as to become irritating to the respiratory passages, it should also not be supplied from exterior sources when fogs prevail and passed into apartments for ventilating purposes without first being dried to the proper degree of humidity and then filtered to remove noxious matters that float in it when fogs exist. In the near future, the problem of purifying air through absorption of hurtful gases and effluviæ of which it may be the vehicle, and the removal of irritating dust particles, will receive far more attention in sanitary engineering than has yet been given to it. We cannot live but a very few minutes without air, while only occasional potations of water are needed; yet the subject of purifying potable water has received the profoundest attention from physicians, engineers, chemists and mechanics employed in furnishing water supplies. In the art of ventilation the purest sources of air supply are sought when an important building, say a hospital, is required to be ventilated: but when a dense fog prevails around such a building there is no source from which pure air can be obtained; it enters the ventilating ducts temporarily loaded with seeds of disease, and these noxious matters, so far as it depends upon any law of nature, are as possible to be removed from the air so entering as are the impurities contained in water. If any difficulties are to be encountered they are likely to be purely practical ones. A promising field for experimental research in this direction is yet comparatively unexplored; and there may be concealed therein a rich reward for the inventor who shall supply simple and sure appliances for rendering air pure for ventilation, regardless of such an external condition as is produced by a dense and persistent city fog.

Change in Business Premises.

A marked change has of late come about in the general features of places where business is transacted. Big business blocks, with light and airy offices, have superseded the earlier and less pretentious buildings where men traded and gathered wealth. That the change is, in most respects, an improvement, is not to be denied. The physical comfort of workers in offices has been enhanced to a great degree by the transition, and it is certainly a welcome change for those who have to visit many offices in the way of business. Until quite recently many old-established business houses were content with, and, indeed, took a species of pride in remaining in, the dingy and cramped quarters in which the founders of the firm had carried on their work. Offices were religiously maintained in the same condition in which they existed during the lifetime of the fathers and grandfathers of the present occupants. They were fearful of ostentation and display, and were conservative to a degree. But now, even these steady-going concerns find they have to march with the times, if they do not wish to fall behind. Even houses with long-established reputations find they cannot insure the maintenance of all their old business if they do not keep themselves perpetually in evidence. They must advertise, and they must let their light shine in as public a manner as possible.

Better Offices.

A name and a dingy office in a back street are not now sufficient. They must do as others do and put their name and business forward so that they who run may read. The old painted board which did duty outside the ancient store or office must be replaced by the substantial metal plate, which is its modern equivalent, suggesting solid wealth and standing. The interior and exterior must be furnished and decorated in accordance with the requirements of modern business procedure. Plate glass, handsome furniture, electric lights and the various conveniences of the day are regarded as evidence of a progressive and up-to-date business house, and are not, as some suppose, looked upon with suspicion, or held to be ostentatious. The tendency of the day is to comfort in business quarters, combined with as much display as is consistent with good taste. And no one can deny that to transact affairs in one of the modern, well-lighted, handsome and attractive offices is a considerably pleasanter matter than it was in some of the ancient dungeon-like premises which flourished but a short while ago.

Moderate Abilities

All men are not born with an endowment of brilliant talents, or even with the faculty for acquiring and retaining knowledge, although this is open to the majority if they will avail themselves of their abilities. Some men there are who are born dull, and who remain dull and apparently incapable of much mental improvement during the whole course of their lives. These are the minority, however, and yet, perhaps, even these might in most cases be open to the reception of more mental thew and sinew had the world the time and patience to take them systematically in hand. But in the rush and hurry which characterize modern life—and especially modern business and trade life—such expenditure of time and trouble is hardly to be hoped for, except in occasional instances. Each tub has to stand more or less on its own bottom, and the dull man almost invariably remains plodding along the lower planes of life and effort, content to remain there to the end of his days. It is not of such cases that we are thinking now, however. An old writer, who was a profound student of human nature, laid it down that mankind might, in respect to their capacities, be divided into three classes—first, those who understand things by means of their own natural endowments; second, those who understand things when they are explained to them; and, third, those who can neither understand them of themselves nor when they are explained to them. In accepting this general classification as substantially correct, we find that the vast majority of the human race naturally fall into the second category, as those "who understand things when they

are explained to them." In other words they are the men of average or moderate abilities. These are the individuals who form the bulk of the workers in all fields of effort. They are the men on whom the real stress and strain of the struggle for existence mainly falls—the rank and file of the great army of humanity.

Advantages of the Average Man.

Many of them, nevertheless, rise to the highest posts of command, by dint of hard effort and utilization of those moderate abilities with which they were originally endowed, together with the capacity for turning them to the best account. The first class above mentioned includes the geniuses and the third the imbeciles of the world, but these taken together form only a small minority of mankind; and, as a rule, even the former are not the men who make the most substantial successes in life. The greatest prizes modern life has to offer are almost without exception—at any rate in the industrial walks of life—open to the men of moderate abilities, and are frequently grasped by them over the heads of the brilliant men whose natural endowments, according to Macchiavelli, enable them to understand things intuitively. If the choice were offered between the two first classes it would not be unwise to desire to be placed, as most of us are placed, among the great mass of average men. It is a great thing to be born a natural king among men, but greater still to have achieved that eminence by fair and hard effort in competition with one's peers. We believe that the majority of those who have climbed to the highest places, and who have worthily filled those places, were men of moderate abilities who merely made the most of their opportunities, and not the men of brilliant natural endowments. In fact, take it for all in all, it is open to question whether it may not be a positive blessing to many men to be the possessors of but moderate abilities, provided they are thereby impelled to use them to the utmost advantage.

The Chicago Smoke Nuisance

The best evidence thus far elicited that the Chicago crusade against bituminous coal smoke is proving effective is seen in the recent organization of a society to protect the smoke makers. Quite a respectable number of manufacturers have agreed to support one another in fighting the efforts of the Society for the Prevention of Smoke. They are supported by some of the bituminous coal merchants, who believe that their commodity is suffering unjust treatment at the hands of the society's agents. An address which has been issued by the "smoke makers," and which states that they have been unable to find economical and efficient devices for the complete combustion of bituminous coal, has called forth quite unexpectedly a most gratifying expression of opinion from other manufacturers, who state that they are using apparatus for the prevention of smoke which they have found both satisfactory and economical. The Society for the Prevention of Smoke, instead of being overwhelmed by adverse sentiment crystallized through a formidable organization, have had their methods vindicated by a chorus of enthusiastic steam-raising supporters in the Chicago daily press. It is quite safe to say that nothing could have happened to give their efforts to suppress the smoke nuisance a greater impetus than this abortive opposition. The fight against smoke makers has been long and bitter, with the result often doubtful, but now the prospects appear to indicate that victory is at last dawning for the smoke preventers.

The Skylight Competition.

The time is drawing near when the Skylight Competition which has been announced for some time past in *The Metal Worker* is to be brought to a close. The date there fixed is the 1st of April, which occurs a week from next Saturday, and we would remind our readers who intend to take part in this competition that the drawings and descriptions must be received at this office by that date, so ample time should be left for their carriage, by mail or express. Some have already sent in their plans, and we believe that the competition will call forth a generous response, for the subject is surely an interesting one, and the various ways in which the problem will be treated will prove instructive to all who are required to do work of this kind.

Winding up of Partnerships.

There are a number of very important practical questions which arise in the winding up of partnerships with which every one in business has need to be familiar.

What will bring a partnership into dissolution, requiring it to be wound or settled up, besides mutual agreement, is the death of a partner, sale of a partner's interest, whether voluntary or upon execution, or the marriage of a single woman. A court will also decree dissolution upon being shown a failure of the undertaking, misconduct of one partner excluding the other or others from joint control over the business, insolvency of a partner, lunacy of a partner, or abandonment of the business by a partner.

Notice of dissolution must be given, except when it is brought about by death, in order to terminate a partner's authority to bind his partner as before. This notice must be actual notice for those having dealings with the firm, but as to strangers, published notice at the place where the partnership was carried on will be sufficient.

The formal dissolution of a partnership and notice of it is very important in order to prevent the possibility of one of the partners, if he took the notion, from binding the other as he otherwise could do, for if the business was merely broken up by sale of the stock one partner could still bind the other by a commercial paper, and perhaps in other ways, as, for example, by admitting a firm debt barred by the statute of limitations.

Upon the death of one member of a partnership, says the Supreme Court of New York in a recent case, the surviving members become the legal owners of the assets, and have the exclusive right to manage and dispose of them in closing up the affairs of the partnership. But while the surviving members of a partnership have the legal title to partnership property, and the right to dispose of its assets, they only have the title and right of disposition for the purpose of closing up the partnership business, not for the purpose of continuing the business. They cannot keep possession of the property indefinitely. The legal representatives of the deceased partner have a right to an accounting by the survivors, and payment over to them of their proportionate share of the assets after payment of the firm debts. However strong may be the desire of the surviving partners to continue the business, the legal representatives of the deceased partner have a right to have the business closed up within a reasonable time, and the capital belonging to them cannot be continued in the business to gratify the desire or promote the interests of the surviving members; and while, under ordinary circumstances, the court will not interfere with the control of the partnership property by its surviving members, or with their management of the firm assets, yet it must be self-evident that there must be power in the court at some time to interfere and cause a final settlement of the partnership business; and when it is apparent that the surviving member or members of a partnership are conducting the business, not for the purpose of closing it up, but to expand, enlarge and continue it, that it then becomes proper for the court to interfere. This may be done by the appointment, on application of the legal representatives of the deceased partner, of a receiver. True, it might be that in some cases it would be better for all concerned that the business should be continued, but neither the surviving partners nor the court can coerce the legal representatives of a deceased partner into leaving his share remain in the business.

The general rule is that the assets of a firm are to be applied in the following manner: 1, in payment of the debts of the firm to persons who are not partners; 2, in payment to each partner ratably what is due from the firm to him for advances, as distinguished from capital put in; 3, in paying each partner ratably what is due from the firm to him in respect of capital; 4, the ultimate residue, if any, is divisible among the partners in the proportion in which profits are divisible under the partnership contract.

The doctrine is also well settled, states the Supreme Court of Appeals of West Virginia, that in a suit between partners for a settlement no final decree can be made while debts due from the firm remain unadjusted, unless the partner asking it will deduct the amount of such debts from the sum which he seeks to recover, and it is an error for the court to decree personally for money collected, or any part thereof, in favor of one partner against the other, until payment of the partnership debts are first provided for, unless good reason is shown for a different course. The reason of the rule is obvious—the partner decreed against is still liable to the unpaid partnership creditors.

THE LETTER BOX.

Removing Water from Cellar.

From D. F. P., *Alexandria Bay, N.Y.*—In reply to "J. E." who asked in *The Metal Worker* of March 4 for a way to get the water out of his cellar, I would refer him to a plan adopted by a resident of this place who was troubled in the same manner. His residence is on a rocky eminence, and the cellar drain, which has to pass under the street to reach the river, was not below the line of frost this winter and became frozen solid. It was a difficult matter to reach the spot, as it seemed to be in the terrace wall, so he took his lawn hose, which was long enough to extend down the terrace some distance, stopped the nozzle end, filled it full of water, put the other end in the lowest point of his cellar and then turned the cock and syphoned all the water out. As I write a good stream is running. By keeping this arrangement working he manages to keep the cellar nearly dry, whereas if he had to dig up his drain it would be a long and expensive job.

Plaster of Paris Molds.

From G. H. R., *Richfield Springs, N.Y.*—Can plaster of paris molds be used for casting brass, copper, silver or gold, if the molds are thoroughly dried?

Answer.—Plaster of paris molds can be used for casting, but it is difficult to get them sufficiently dry for the purpose, on account of the water contained in them, and which was used in mixing the plaster. This difficulty can be overcome to a certain extent by holding the molds over burning tar or kerosene, thus giving them a slight coating of soot or carbon. A piece of tar paper or a common kerosene lamp without a chimney can be used for the purpose.

Tinning Old Copper Wash Boilers.

From C. F. T., *Toledo, Ohio.*—I would like to know how to tin old copper wash boilers, as so many of my customers want this work done for them. I wish you would furnish this information through the columns of *The Metal Worker*.

Answer.—This question, or a similar one, has been answered several times before in the columns of *The Metal Worker*, and from these previous accounts we condense the following notes about the work. The first thing to do is to thoroughly clean the copper, which is done by washing it repeatedly with commercial muriatic acid, using a swab of tow to assist in the operation. After having cleaned it with the acid, take sharp sand and thoroughly scour it; then rinse it off perfectly clean and examine it closely to see that no foreign matter remains. To tin the vessel, first wet it all over and let it drain, and while damp sprinkle the inside surface with some sal ammoniac. Then place it over the fire and warm it until the sal ammoniac begins to smoke and dissolve from the heat. A few pounds of tin having been melted in a ladle, taking care not to burn it, pour a portion of it in the copper vessel and flow it around with the help of a wad of sal ammoniac. If the tin refuses to adhere to any part, rub the place well with sal ammoniac. After the vessel has been tinned in all parts, turn it upside down and let the surplus tin drain off.

Equalizing the Temperature of Rooms.

From R. N. W., *Pa.*—How can I manage to draw cold air out of rooms so that the temperature will be the same at the floor level as it is in the more elevated parts? What method would answer for this purpose for a large room, such as a hall or a church.

Answer.—The desired result can be attained by properly ventilating the rooms by outlets either near the floor level or located in the floor itself. These outlets must be ample in area, and connected with flues or ducts of sufficient drawing power to take the cold air out. A simple way to draw the cold air from any ordinary room is to place a register at or near the floor, connected to a heated flue; a chimney flue will answer for the purpose. It is often the case in a building such as a church or a hall that no provision has been made for the flues needed for this purpose. In such a case they will have to be built, located at such places in or against the walls that they will take the cold air evenly from all parts of the floor. Such ducts, to work, must be heated. This can be accomplished by placing a small heater at the base of the duct, the smoke pipe from the heater passing up through the entire length of the duct to the outside above the roof. A small fire in the heater will cause an upward movement of air drawn from the floor into the duct. The heat generated by one or two gas jets located near the bottom of the duct in some cases is sufficient to accomplish the desired result. Another method made use of in some instances is to connect a small pipe from the furnace hot-air chamber to each duct.

The Tinners' Trade.

From JOHN BAKER, *Fort Wayne, Ind.*—I read the article in *The Metal Worker* of March 4 on trade education and the difficulty of procuring competent workmen. What inducement, however, do employers offer to an intelligent boy to learn the tinsmiths' trade? The first thing he has to do is to clean up a dirty and often insufferably hot shop, for every one in the store, after it is cleaned up, to upset again. The clerks come in and black their shoes on the bench and dirty the whole place. All this the apprentice boy has to clean up. Next, he is made a beast of burden and has to take loads of tools and tin to all parts of town, sometimes lugging a fire pot half the size of himself. Finally, when he has spent about two years at this kind of work (I can't call it a trade), another boy is taken to learn the work, and these constitute the jour. and helper in nine shops out of ten. And then if he is so unfortunate as to become a good workman, how is the case with him then? Every one is supposed to tell him what to do, and he has all sorts of menial jobs that no other tradesman will undertake. They all say, go to the tinner for such work.

Chimney Connections for Gas Ranges.

From G. W. H., *Germantown, Ohio.*—In discussing the cause and remedy of condensation from a natural gas range one's mind is very naturally switched off in several other directions. The amount of moisture given off from a natural gas flame is so great that nothing short of absolute flue connection will carry it out of the room. A canopy or other device will not do. The range itself must be made so as to conduct the products of combustion to a pipe without the possibility of their being distributed in the room. It must have as direct and complete flue connection as any coal or wood stove should have. There are quite a number of heating devices on the market for which the makers never expected or thought of flue connections. All this is radically wrong, and the sooner the manufacturers tumble to this fact the better. In this State the authorities are raising considerable racket about adulterated or impure food. I would like to know what would be the matter with a law to regulate heating devices. Approximately, heating arrangements are as deleterious to health as impure food. All oil, gasoline, gas, patent fuels, from which the products of combustion are discharged directly into the room where used, are injurious to health. Electric heating may solve the problem, but that is further along. These fad devices are sold to seemingly intelligent people. Gullible merchants, ministers, and even doctors have been buying them, and nearly smothering themselves and their friends with the gases which must result from the combustion of any form of carbon. Instead of being the agents and means of foisting these humbugs upon the public, the merchants should stand as a stone wall against the distribution of this class of goods.

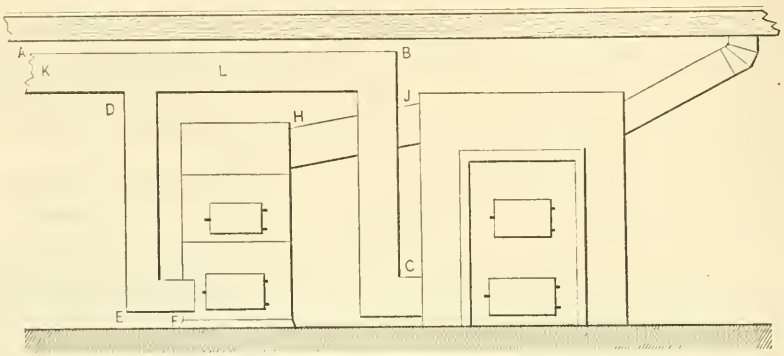
Note.—That the burning of oil and gas gives off harmful gases goes without saying; but we think our correspondent takes rather extreme views as to what should be the action of dealers in the matter. The products of combustion from a gasoline stove, for instance, are poisonous, but so are the gases that are breathed out by human beings and animals. A room would have purer air if every flame, whether of a stove, a lamp, or the flame of a candle, were connected with a chimney flue and every individual had a special exhaust pipe to breathe into, but such a multiplication of ventilating ducts would be out of all reason. A sitting room with ordinary ventilation may have one or more kerosene lamps in it without affecting the health of the occupants, and the same amount of oil burned in a stove would not vitiate the air any more than the lamps vitiate it. The thing to do is to deal with the problem reasonably, and this means the connecting of

ranges and stoves of any sort with chimneys if the air is vitiated by them to an unwholesome degree.

Two Furnaces Connected with One Cold-Air Box.

From E. D., *New York.*—The following diagrams are intended to illustrate the cold-air box for the portable furnace, the one supplying the large furnace was tapped and the pipes arranged as shown in Fig. 1. A great advantage to be derived from this scheme was, that no changes were required in the heating pipes—only one of which is shown in the engraving—leading from the brick-set furnace to the rooms above. The original cold-air box which was constructed to supply the brick-set furnace is represented by A B C, and the branch leading to the portable furnace by D E F. Dampers were placed at K and L, damper K to be used for regulating the supply of air from outside.

During moderate weather the portable furnace only is used. Damper L being closed, the air is required to pass down the cold-air box D E F and through the furnace, where it becomes heated. It then passes through the connecting pipe H J into the brick-set furnace (in which there is no fire), and up the various pipes to the rooms above. By this arrangement the upper part of the brick-set furnace serves as a warm-air reservoir from which the various heating pipes draw their supply.



Two Furnaces Connected with One Cold-Air Box.—Fig. 1.—Arrangement of Fresh-Air Pipes.

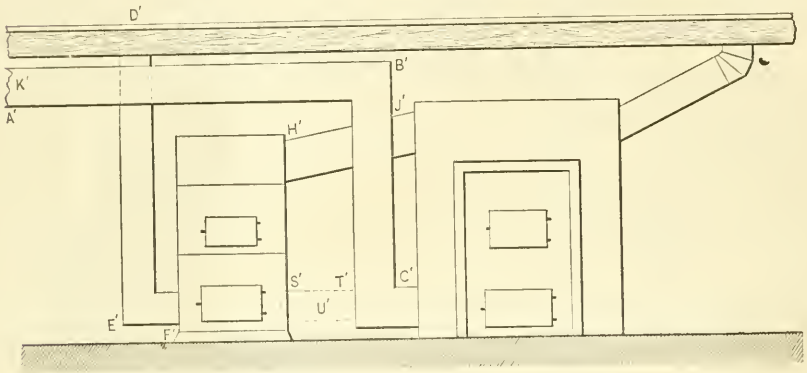


Fig. 2.—Portable Furnace Supplied with Cold Air from Hall.

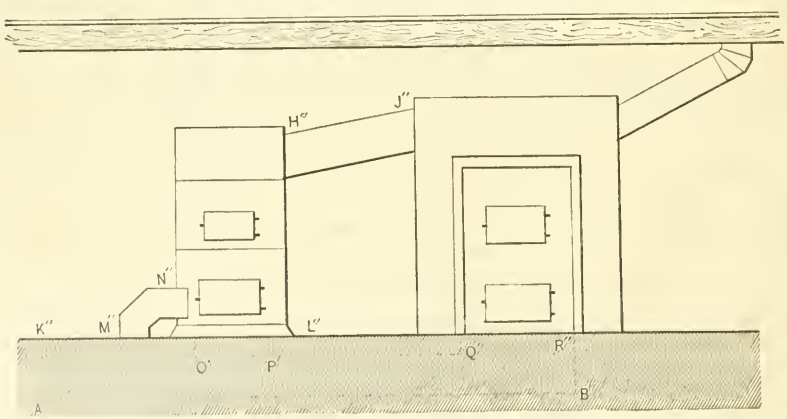

Fig. 3.—Two Furnaces Connected with Underground Duct.

The weather becoming colder, and more heat being required to warm the house, the brick-set furnace can be used. Damper L is opened, thus allowing the air to pass through the box A B C to the furnace where it becomes heated and passes up the various heating pipes. When the weather becomes excessively cold the two

manner in which two furnaces were connected with one cold-air box. The brick-set furnace was first in use and found insufficient to properly warm the house during extremely cold weather. Accordingly a small portable furnace was connected with the brick-set, and as it was not convenient to construct a separate

furnaces can be used together. The damper L is to be turned so each furnace will receive its proper supply of air.

Another scheme is shown in Fig. 2 that might be desirable under some circumstances. The cold-air supply for the portable furnace is derived from the hall or any convenient room, as indicated at D, and the air passes to furnace through D E F. A register placed at D could be used for regulating the flow of air. By this arrangement the cold-air could be taken from the rooms above for supplying the portable furnace, and from outside, through the box A B C, for the brick-set furnace.

By connecting the portable with the brick-set furnace, as indicated by S T, and placing a damper at U, another combination would be the result. When the portable furnace was in use, by closing damper U the air could be taken through D E F. By closing register D and opening damper U and K, the air would pass into portable furnace through A B T S.

The brick-set furnace being in use, by closing damper U (damper K open), the air could be taken through A B C. Then by closing damper K and opening damper U, the air would pass through D E F and S T. When the two furnaces were in use, the damper U could be closed and damper K opened. D E F would then supply the portable and A B C the brick-set. With register D closed and dampers U and K open, A B C could supply the two furnaces. Damper K being closed, and register D and damper U being open, D E F could be used for the two furnaces. In this case the air would be obliged to pass through the portable before entering the brick-set furnace.

In Fig. 3, the two furnaces are shown connected by the underground duct A B. The brick-set furnace receives its supply of air at Q R. A similar opening can be made for the portable, as indicated by O P, or an elbow can be used to connect the duct with furnace, as indicated by M N. By placing dampers at K and L, the cold-air supply can be controlled and the furnaces managed in the same manner as shown in Fig. 1.

Price of Material.

From E. P. B., *Osterville, Mass.*—I would like the opinion of the readers of *The Metal Worker* regarding the profit to be added to the cost of material used in jobbing. For a number of years I have been using quantities of copper, and it has been my custom to add a profit to cost of same, besides charging for my time. Sometimes I have an argument with a customer regarding the subject of profit on material, and so would like the advice of others.

In the library of Congress, says an exchange, which has over 650,000 bound volumes, the books will hereafter be handled almost entirely by machinery. Orders will be sent to the book-stacks and books brought from them to the desk for distribution by trays suspended from endless chains, the latter being made to travel by means of an engine in the basement. The mechanism will be noiseless and invisible also, the carriers going beneath the floor of the great central reading room, to and fro between the librarian's desk and the book-stacks. Every arriving tray will dump itself automatically at the first desk. Likewise, in taking volumes back, each tray will spill its contents, of its own accord, at a certain tier.

From a Western contemporary we learn that Pope's Theatre in St. Louis possesses one convenience which could be adopted with profit by all other similar places of amusement. In inaugurating the season of 1892 93, the management of this theatre has given the purchasers of its seats telephonic communication, enabling those attending the performances to be called quickly in case of necessity. By leaving their seat numbers in the box office they can be called immediately.

NEW PUBLICATIONS.

REPORT OF THE CHIEF OF MASSACHUSETTS DISTRICT POLICE FOR THE YEAR ENDING DECEMBER 31, 1892, INCLUDING THE RESULT OF THE INSPECTION OF FACTORIES AND PUBLIC BUILDINGS. Boston, 1893.

The records of the inspection and detective departments or the State police force of Massachusetts for the year 1892 fill a handsome volume of 500 pager, containing numerous well-executed plans and illustrations of systems pursued and proposed for the heating and ventilation, as well as general arrangements of schoolhouses and public buildings in the State. The division of work between the two branches of the force—namely, the detective department and the department of inspection of public buildings and factories, which was instituted in 1888—is stated to work admirably. Of the 37 officers who compose the executive, 26 are detailed for service in the inspection department, leaving 11 for detective duty. The former are not called upon to perform any other duties than those pertaining to the office of inspector of factories and public buildings, except in cases of great emergency. Among other interesting topics treated of by Chief of Police Wade are the means taken for the prevention of elevator accidents by legislation and rigid inspection, the 58-hour law, regulations for the erection and construction of public buildings, arbitration of labor disputes and a review of the working of labor and inspection laws in the commonwealth. Perhaps the most important portions of the document are the reports and remarks in regard to ventilation and heating of schoolhouses and other public buildings. This matter appears to have received very full and earnest consideration at the hands of Mr. Wade and his staff of inspectors. Chapters on "Ventilation Practically Considered" and "Ventilation by Mechanical Means" furnish some valuable suggestions on this important but too-often neglected subject.

AMERICAN NEWSPAPER ANNUAL. N. W. Ayer & Son, Philadelphia. Price $5.

The "American Newspaper Annual" for 1892 is the thirteenth edition of this valuable compilation of the newspapers and periodicals published in the United States and Canada, and shows that the development of journalism, press and class, is keeping pace with the growth of population and increase in intellectual and industrial progress.

The work under review is not only a catalogue of newspapers, giving information concerning their circulation, issue, date of establishment, political and other distinctive features, together with the population of the counties and places in which the papers are published, but it also furnishes a description of every place in the United States and Canada in which a newspaper is published, including railroad, telegraph, express and banking facilities, thus forming a valuable guide to advertisers and the public in general.

Some interesting information is presented regarding the growth of journalism in this country. In the present edition 20,115 newspapers and periodicals are enumerated, an increase over last year of 1104. It is stated that the increase is due partly to the average yearly net gains of from 800 to 850 and partly to the fact that the Presidential election always adds temporarily to the number of papers. In 1879, according to best authority, the number of papers in existence was 10,115, or exactly 10,000 less than the present count. In the ten years since 1882 the average net annual increase has been 831. These figures, however, it is stated, give no idea of the number of papers started in any one year. Probably not less than 3500 publications of all kinds have sprung into existence since work on the edition of 1891 was closed, but of over 3000 recorded many ceased publication with the first or a very early issue.

There were published in the United States in 1892 14,204 weekly, 2188 monthly and 1806 daily papers. New York leads, with 1902, followed by Illinois, with 1572; Pennsylvania, with 1384; Ohio, with 1112, and Iowa, with 975.

The "American Newspaper Annual" embraces 1426 pages of descriptive, statistical, advertising and miscellaneous matter, and the method of indexing employed makes it possible to turn to the information desired without loss of time.

New York's Water Supply.

The question of contamination of the water supply of New York City, in view of a prospective visitation of cholera, is now occupying the minds of the medical fraternity and the public generally. A special meeting of the Academy of Medicine was held last week to consider the subject and to hear the report of a committee recently appointed to confer with the city Board of Health. In support of complaints of pollution, it was shown by one of the members of the committee that the condition of some of the feeders of the Croton River, from which New York's water supply is obtained, is such as to be a deadly menace to health. One tributary was found to be actually an open sewer for a large village through which it flows. Drainage from barnyards, vaults and other sources of pollution was seen to empty directly into this brook, which even receives the percolations from cesspools, as well as the garbage and offal of the whole village, including human excrement. Small wonder that, when such a state of things exists, the medical profession should think it time to sound a clear note of warning of the impending danger. Should cholera come this year a contaminated water supply will be the most effective medium of assistance in its ravages. It appears that the laws of New York State do not provide any effective method for checking such pollution of streams as is described above. Great efforts are therefore being made to initiate such measures as will insure the immunity of the city's water system from dangerous sources of contamination. The medical profession have taken the lead in the movement and have collected abundant evidence to show the reality of the danger. They propose that a special board of sanitary engineers, chosen by the State, should be invested with large powers in dealing with this matter. The matter is a larger one than a mere city question. It really concerns the whole country, for should the scourge of cholera unhappily arrive this summer, New York would in all likelihood be the first place of its appearance, and if the plague is to find the assistance of impure drinking water awaiting it there, the chances of its suppression or confinement to a small area will be greatly lessened.

A Berlin correspondent, discrediting the reports of negotiations in progress for a new commercial treaty between the United States and Germany, says: "It is likely enough that, should the disposition of the new American Government be favorable, Germany might try to make some commercial arrangements with the United States, but there is little chance for a treaty which would materially improve the commercial relations between both countries."

WORLD'S FAIR NOTES.

The Forestry Exhibit.

Out on the lake shore, near the southern extremity of the World's Fair grounds, is a structure that differs materially from any other in the park. The Forestry Building is *sui generis*. After seeing the magnificence of staff construction in the large buildings it may be with relief that some visitors will turn to the rustic simplicity of the forestry building. Instead of the intricate work of designers, molders or artists, the highest effects in the forestry building come from groupings of natural woods. No other building on the ground shows so clearly at first impression the uses for which it is designed.

The scope of the World's Fair forestry exhibit is of peculiar interest to Americans. When a separate department of forestry was created, it was pointed out that the opportunity had arrived to make constructive forestry as important a science in this country as in Europe. On this idea the fair managers have worked with a will. Although constructive forestry and the restoration and preservation of forests are yet in their infancy in America, it is believed that the turning point has arrived and that the World's Fair exhibit will have a most potent influence in preventing the further wholesale destruction and waste of native forests.

The Forestry Building itself is the main exhibit in the department. It is 200 x 500 feet in area. On all four sides is a veranda, with supports forming an imposing colonnade. This colonnade is one of the most unique affairs ever designed and is peculiarly appropriate to a cosmopolitan fair. It is built from woods contributed by foreign countries and about 30 States and Territories. It consists of a series of columns, each composed of three tree trunks 25 feet long. One of the trunks in each column is from 16 to 20 inches in diameter at the base and the other two are from 9 to 12 inches. All the trunks have the natural bark of the tree. Each of the States, Territories or foreign countries furnishes specimens of the most characteristic timber growths within its borders. The sides of the Forestry Building are built of slabs with the bark removed. The rest of the building, including the window frames, has the same rustic treatment. The roof is thatched with tan and other barks.

The main entrances are finished in different kinds of wood and are very elaborate. The one on the east side, facing the lake, deserves special mention. It is put in place and finished by the Southern Lumber Manufacturers' Association. The vestibule is of yellow pine and cypress. It is built in such a way as to show the susceptibility to polish of the Southern woods and their usefulness for panels and interior decorations. The cost of this main vestibule alone was between $5000 and $10,000. Some of the States—Alabama, for instance—have sent tree trunks for the Forestry Colonnade, although prohibited from making an interior exhibit by lack of appropriations. The tree trunks in the columns taper toward the top and are joined by rustic work in longitudinal sections. Some of the latter are also furnished by the States contributing the columns. On each column there will be a tablet, giving the common and scientific names of the trees and the State or country contributing them, besides other valuable information concerning the resources of the locality. Above the cornice of the veranda, on all four sides of the building, are flagstaffs, which will bear the colors or coats of arms of the nations or States represented in the interior exhibits.

The interior exhibits will be in several main groups. Natural woods will be shown exclusively by States, Territories and foreign countries. The product of the various woods, finished or partially finished, will be shown by individual exhibitors or firms. The methods and processes of manipulating timber at every stage, from the tree trunk to the finished product, will be shown by firms or corporations. The completely finished product will not be shown in this building, as it belongs to the department of manufactures; neither will there be any machinery in motion in the Forestry Building. It will be a still exhibit, but the various ways of denuding forests for economic and commercial purposes will be shown by models, maps, drawings and other methods.

The foreign countries which have obtained space inside the Forestry Building are Japan, Honduras, Peru, Hayti, Spain, Germany, Ecuador, Colombia, Brazil, Mexico, New South Wales, Canada, Russia, Italy, France, Siam and India. Each of these countries has a separate space, and will make a showing of its most characteristic woods. Miniature structures will be built, with arches and railings of natural wood and in rustic design. Canada has the largest space of any foreign government, and the various provinces of the Dominion have promised to make an interesting showing of their timber resources.

The States and Territories which will have interior exhibits are: Pennsylvania, Louisiana, Virginia, Arizona, Kentucky, Minnesota, Nebraska, Montana, Wyoming, New Mexico, Wisconsin, North Dakota, Ohio, Washington, Michigan, West Virginia, Missouri, North Carolina, Indiana, Maine, New York, California, Utah and Idaho. Of these West Virginia and Michigan have the largest space, and the exhibits from these States will be on an elaborate scale. Other States will show peculiarly unique specimens, and the grouping of woods in the various spaces will form a most artistic whole. Sections of tree trunks will be built one on top of the other, and each portion of the exhibit will be accompanied by detailed information as to the locality producing the exhibit, the area still under growth and where located, and all other pertinent information.

It is one of the rules of the forestry department that there shall be no finished wood products in the building, and where it is necessary to show the special uses of certain kinds of woods it will be shown by pieces of disjointed furniture or other partially finished product.

The foreign exhibits will include all the remarkable woods and wood products that are familiar in name only to Americans. The India exhibit will include sandal woods and a precious Government collection of unique and valuable woods. Brazil will show the various grades of mahogany, California the red wood and gigantica, Canada the various pines, birch and maple and a host of other trees of commercial value.

Some of the State exhibits will be peculiarly interesting. Nebraska will show the results of tree planting and the special results of the observance of Arbor Day in that State. This exhibit will contain specimens of actual woods, with tabulated information showing the age of each specimen, how and when planted. North Dakota will make a similar exhibit. Some of the exhibits will be genuine surprises. For instance, Kentucky, which is not popularly considered a forest State, will show as elaborate an exhibit as most of its neighbors. From Kentucky there will be specimens of white oak, 4 or 5 feet in diameter, built in the form of a pyramid. Kentucky will also show a very fine relief map, pointing out the principal forests in the State, with full statistical information regarding them. Ohio, Wisconsin and North Carolina will make exhibits of medicinal plants and herbs gathered in those States. Ohio alone will show varieties of medicinal herbs amounting to 400 or 500. This is a new feature in American exhibits.

One of the remarkable foreign exhibits will be from Paraguay, which will show 321 varieties of woods, each 1 meter high and from 12 inches to 4 feet in diameter. In this exhibit will be beautiful specimens of barks, dyewoods and other commercial products of that portion of South America. The Argentine Republic will have an exhibit of remarkable woods. France and Germany will have the best scientific exhibits, giving illustrations of constructive forestry from the results of wide experience. Japan will make a most creditable showing, and the various wood specimens from the flowery kingdom will be the first ever shown outside of that country.

Among the spectacular exhibits will be an immense trophy in the center of the building. This will consist of a collection of large natural timbers from various States. North Carolina will send a large walnut log, Kentucky will send a mammoth white oak, Kansas will send a walnut log 7 feet in diameter and weighing 30,000 pounds. There will be immense tree trunks from the State of Washington. Another spectacular exhibit will be a long spar of ship timber from Washington.

The individual commercial exhibits will include specimens of wood pulp, cork, parts of furniture and wooden ware. The pulp industry, which is rapidly growing in importance, will be represented by several exhibitors from foreign countries. The World's Fair exhibit will contain the most complete display of the utilization of wood products that has ever been brought together.

Outside the Forestry Building, but connected with the department, there will be shown a typical logging camp. This is contributed by Michigan, and will be located at the south end of the park.

Logging methods will be shown, including snowsleds loaded with logs, saws, axes, chains, skids, rollers and old implements used in the early days by the lumbering industry. There will also be a typical logging hut, showing how lumbermen live in the back woods. In another part of the grounds, near Machinery Hall, will be shown an actual sawmill in full operation. The process of converting logs into various kinds of lumber will be gone through on a realistic scale.

To practical builders from other countries the Forestry Building itself will convey many suggestions as the American methods of house raising. There was not a single nail used in the construction work. The method of construction followed by Mr. Atwood, the designer, is intended to show peculiarly American methods of joining timbers so as to economize materials. Wooden pins were used instead of nails.

An Official Change.

After having served the exposition as mechanical and electrical engineer for 18 months, Frederick Sargent last week tendered his resignation to Director of Works Burnham, and it was promptly accepted. The Council of Administration lost no time in approving Mr. Burnham's action.

Mr. Sargent's resignation hardly caused a ripple of surprise among the exposition officials, although it came unannounced. It has been known for several months that affairs in the department of electrical and mechanical engineering were dragging. Mr. Sargent, when questioned by the council concerning the progress of the work in his department, returned answers that were most unsatisfactory. Finally he was asked whether the electrical and mechanical engineering would be completed by May 1. He replied that it would not.

Then Mr. Burnham interrupted with the assertion that the engineer was mistaken, and that the work would be completed. Shortly after that meeting the affairs of the department were reorganized. R. H. Pierce was given charge of the electrical division, and Charles F. Foster the mechanical department.

This having been accomplished and everything made ready for renewed action, the resignation referred to was next in order.

Silver Statue to be Cast Soon.

Commissioners W. M. Bickford and Dr. A. H. Mitchell of Montana are in Chicago to superintend the casting of the silver statue for the World's Fair, and within the next ten days the image of Ada Rehan will be taken from the molds of the American Bronze Company and presented to the gaze of the public. The National Smelting & Refining Company have 11,994 ounces of the silver and an additional 12,000 ounces was delivered to the commissioners last week by the Adams Express Company from the Omaha smelters. The white metal is from the Moulton, Curlew, Elizabeth and Wickes Mines, all of them noted silver producers, and the World's Fair Board is under bonds for its safe return to its owners. Invitations will be issued by the American Bronze Company to a public pouring, and the casting will be conducted with due ceremony. The heads of the departments of the exposition will be in attendance and Chief Skiff will pour the metal into the mold. Several Montanians will be present at the ceremony.

Fete Days at the Exposition.

The following is a complete list of special fête days as arranged up to date by the Committee on Ceremonies:

Washington	May 17
Wisconsin	May 23
Maine	May 24
Denmark	June 5
Germany	June 15
Nebraska	June 15
Massachusetts	June 17
New Hampshire	June 21
France	July 14
Utah	July 24
Liberia	July 28
Commercial travelers	July 26
Independant Order of Foresters	Aug. 12
Hayti	Aug. 16
Colored people	Aug. 25
North Carolina	Aug. 18
Austria	Aug. 18
The Netherlands	Aug. 31
Nicaragua	Sept. 1
New York	Sept. 4
Brazil	Sept. 7
California	Sept. 9
Maryland	Sept. 12
Michigan	Aug. 13 and 14
Kansas	Aug. 15
Colorado	Sept. 19
Montana	Sept. 20
Patriotic Order Sons of America	Sept. 20
Iowa	Sept. 21
Rhode Island	Oct. 5
Spain	Oct. 12
Italian societies	Oct. 12
Minnesota	Oct. 13

Arrival of a Large Cannon.

One of the biggest guns belonging to the United States Government was shipped into Jackson Park last week for installation in the Government Building. It is not the biggest gun in this country because there are two or three others of equal size, but none larger. It is 36½ feet long and weighs 58 tons. It is a 12-inch breech-loading steel rifle and will carry a projectile weighing 1000 pounds. A charge of 460 pounds of powder is used every time the lanyard is pulled. A specially constructed twin car was required to carry the gun. Each car used was 70 feet long and built of steel. The cannon rested on a truss, or bridge, the center of which was over the couplings of the cars. Great care was manifest in the making of the little train. Each car was provided with 12 wheels of steel, and on each was a brake to secure the instant stopping of the train in the event of that being necessary. On arrival at the Government Building three big gun lifts were placed over the car and three immense chains wound about the cannon and by means of hydraulic jacks the gun was lifted slowly upward and the special cars pulled from beneath it. The cars were returned to the East, and will be used to carry the Krupp cannon, which is expected shortly. The Krupp gun will be almost twice as large as Uncle Sam's specimen cannon. It will weigh 128 tons and have a bore 25 inches in diameter.

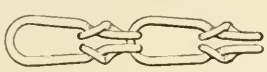
The cannon which reached the park last week came from the United States arsenal at Watervliet, N. Y. It has never been tested. There is a companion gun of its size at Sandy Hook, N. Y., and several shots have been fired from it. It will throw a projectile at least ten miles.

British Exhibits.

Pitt & Scott, foreign carriers, have shipped from London several hundred tons of exhibits for the fair. The exhibits are of a most varied description and include a number of models of steamships, among which is the model of the famous Confederate cruiser Alabama. This model is sent by the builders, Laird Bros. of Birkenhead. Another package measuring nearly 50 cubic tons was shipped last Friday and contains a large model of Her Majesty's steamship Victoria, which was exhibited at the naval exhibition in London. This model is forwarded by Armstrong & Co. of Newcastle-on-Tyne.

The Strength of Small Chains.

In a paper read at the meeting of the British Association at Edinburgh, in 1892, Professor H. S. Hele-Shaw states that he has frequently found the result of using small chain most unsatisfactory. In the



The Triumph Chain.

first place, no small chain which he has been able to procure seemed to give a reasonable amount of strength in proportion to its weight and the tensile strength of the material. In the second place, no maker will usually give any guarantee of strength below a certain size, generally $\frac{1}{8}$-inch, although in some special cases makers will guarantee the strength as low as $\frac{1}{4}$ inch. Below $\frac{3}{16}$ inch no strengths are ever quoted in text books, engineering pocket books, or books of engineering reference.

Commenting on data found in engineering works, the author says that these data are not very satisfactory in themselves, and there are no results of chain of less than $\frac{3}{16}$ inch diameter; whereas enormous quantities of chain under this size are made and sold.

Recently there have been a number of tests on the strength of small chains in the Walker engineering laboratory. These tests include all sizes of chain up to $\frac{1}{4}$ inch diameter that could be bought or procured either in shops or from wholesale makers.

The result of these tests is given in five tables, under the following heads: Single Jack, Double Jack, Ordinary Welded, Triumph (American), shown in the engraving, and Miscellaneous (brazed and odd-size welded). Of these we print the two most interesting:

English Welded Chain.

Maker's size.	Diameter, inches.	Area, square inches.	Strength in pounds. Test I.	Test II	Test III.	Average strength in pounds.
13	0.496	0.00769	295	369	369	344
10	0.127	0.126	546	535	537	539
9	0.146	0.0167	633	598	624	618
6	0.155	0.0188	1,097	920	1,164	1,060
5	0.181	0.02 7	1,214	1,256	1,181	1,217
4	0.223	0.39	2,226	1,711	2,058	1,998
3	0.252	0.0 68	2,826	2,735	2,694	2,751
2	0.296	0.0555	3,389	3,934	3,158	3,476
1	0.283	0.0629	4,204	3,852	4,408	4,154

American Triumph Chain.

Maker's size.	Diameter, inches.	Area, square inches.	Strength in pounds. Test I.	Test II.	Test III	Average strength in pounds.
7	0.058	0.0022	284	286	280	283
6	0.057	0.0 0 25	322	322	320	321
5	0.068	0.0063	408	452	448	428
4	0.071	0.00395	506	497	474	492
3	0.084	0.00554	661	681	688	676
0	0.120	0 0113	1,290	1,281	1,315	1,295
00	0.135	0.0143	1,046	1,500	1,568	1,401
000	0.149	0.0174	1,996	2 000	2,049	2,015
4-0	0.164	0.0211	2,484	2,522	2,607	2,531
5-0	0.178	0.0248	2,927	2,976	2,950	2,951
6-0	0.22	0.038	3,772	3,801	3,747	3,773

In every size three tests of ultimate strength were made, the results of which, in pounds, have been recorded, the average being given in another column. The want of uniformity in results is sufficient to explain why no values for strength are given by the makers and why the recorded results in books differ so much.

The chief effect to be noticed is the extraordinary strength of the new American chain, which, on an average, is twice as strong for every corresponding size as the English welded chain; five times as strong as the double jack chain, and eleven times as strong as the single jack chain, and, in every case, gave way, not as in the case of the jack chain and welded chain at the joints, but in the material itself.

A further experiment was made of twisting a piece of iron wire into the form of the American link, and then testing the link and afterward the wire itself, when it was found that the strength of the link was about 1¼ times the strength of a single section of the iron wire from which it was made. The author understands that this chain is not yet manufactured in England, but steps are being taken to introduce the machines necessary for the purpose.

A very neat method for coating sheet steel with copper is being developed by W. B. Hollingshead of Bronxville, N. Y. He deposits copper electrically and then rolls the sheet. Upon this he deposits a second coat and rolls it again, or works it under a planishing hammer. Some fine specimens of sheets thus coated have been made, opening a promising future for the material. Mr. Hollingshead aims to overcome by his method the drawbacks incident to the crystalline and loose nature of electrically deposited coats of copper.

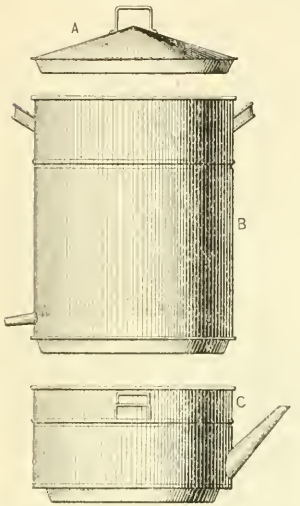
The annual catalogue of the Massachusetts Institute of Technology shows that of the 132 graduating members of the class of 1892, 22 graduated in civil engineering, 26 in mechanical engineering, 4 in mining engineering, 36 in electrical engineering, 4 in chemical engineering and 6 in sanitary engineering. The total registration this year has been nearly 1100.

THE TIN SHOP.

A Wax Extractor.

BY OLIVER TWIST.

In the first place, it may be well to say what it is for, although the name is almost enough for the dullest man to understand



A Wax Extractor.—Fig. 1.—Cover, Body and Boiler.

that it is for extracting wax. From what? Well, we will try to explain. After taking the honey-comb from the hive and extracting the contents by means of a honey extractor, the comb itself is left, but in such shape that it is not in a fit condition to be

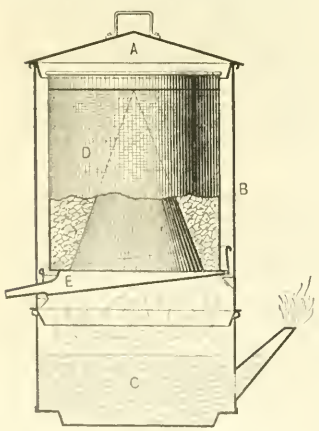


Fig. 2.—Sectional View of Wax Extractor.

sold as wax. This is where the wax extractor comes in to melt the wax and to separate from it any wood slivers or other matter which it may have collected, so as to get the wax in a salable condition. In Fig. 1 the different parts are shown separately, A being the cover; B the body or outside shell; C, the boiler, to contain water, which will produce the steam to circulate up through and around the perforated cylinder D (illustrated in Fig. 2) containing the wax. This, when melted, will fall through the perforations into the pan E, shown in Fig. 2; and so out of the spout into the molds or any vessel placed to receive it. Fig. 2 gives us a peep inside, or, in other words, a section, showing the different parts in their proper places and ready for use.

The boiler C can be made with an ordinary No. 9 tea kettle-pit, which can be bought, ready spun, cheaper than it could be made. Take two sheets of tin 14 x 20 and one sheet 7 x 20. Cut 5 inches off the end of each sheet, which will give two pieces 5 x 14 and one piece 5 x 7, which, when grooved together lengthways, will make a strip 5 inches wide and about 34 inches in length. This will just make the circumference of a No. 9 spun tea-kettle pit. The other two pieces will be 15 x 14, and one piece 15 x 7, which, after grooving together as before, will be 15 inches high and 34 inches long to make the body B. If you make two of these extractors at once you can get two of each kind—that is, B and C—out of five sheets of 14 x 20 tin, exactly. The cylinder D, Fig. 2, is made from perforated tin. After double seaming the bottom (you can do this in the usual manner if you are careful), cut a circle out of it about 7 inches in diameter, in order to admit the cone which is shown inside, and which is also made of perforated tin. To protect the upper edge, and in order to make it strong, wire a rim about 2 inches wide, as shown in cut, and solder on inside the cylinder. The rough edge of the perforated tin will then finish underneath the wire edge, thus making a smooth job. E, Fig. 2, is a pan about 2 inches deep, placed on an incline and supported with lugs. This may be adjusted permanently, as it cannot be removed, owing to the spout passing through the outer shell B. The cylinder D, however, is to be removed occasionally, and is provided with rings for that purpose. The body B, of course, has no bottom, simply the rim to set down into the boiler C.

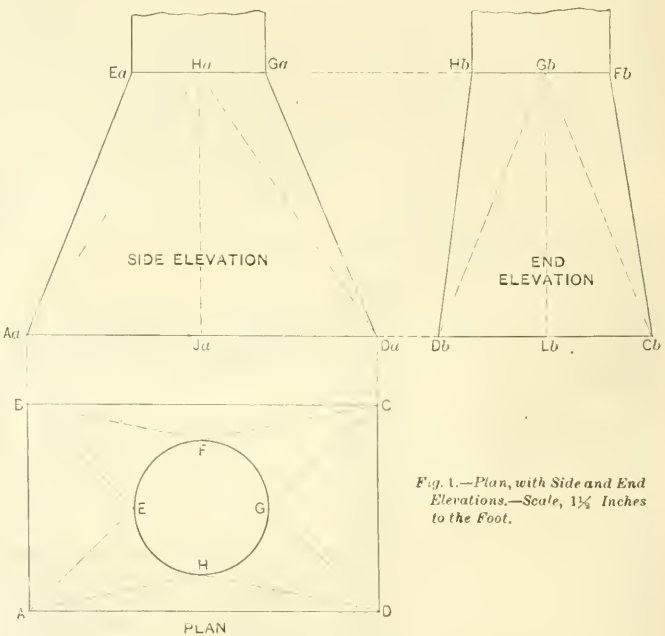

Fig. 1.—Plan, with Side and End Elevations.—Scale, 1¼ Inches to the Foot.

PATTERN FOR CHIMNEY TOP.

Pattern for Chimney Top.

From L. N. H., *Milroy, Pa.*—Will you, please publish a short and simple rule for describing the pattern for a chimney top, square or oblong at the base and round at the top?

Answer.—There is always a call for short and simple rules for describing the various patterns used in connection with sheet-metal work. The "short and simple" part of a rule could be said to depend upon one's understanding the underlying principles upon which a rule is founded.

The underlying principles being thoroughly understood, much of the drawing necessary to show the article from various Ea Ga Da, and at the right the end elevation, as indicated by Db Hb Fb Cb. The slant hight of Ja Ha of side elevation elevation, the ends of two triangles similar to D G C, and the four "corner" pieces as C G F, which are sections of oblique cones. The reader is at liberty to determine how necessary the elevations are for an understanding of the required shape.

In Fig. 2 is shown a duplicate plan of the article. The patterns for side, end and one of the corners will be obtained separately, the plan being used for the purpose, in connection with the hight of the article. To obtain the pattern of one of

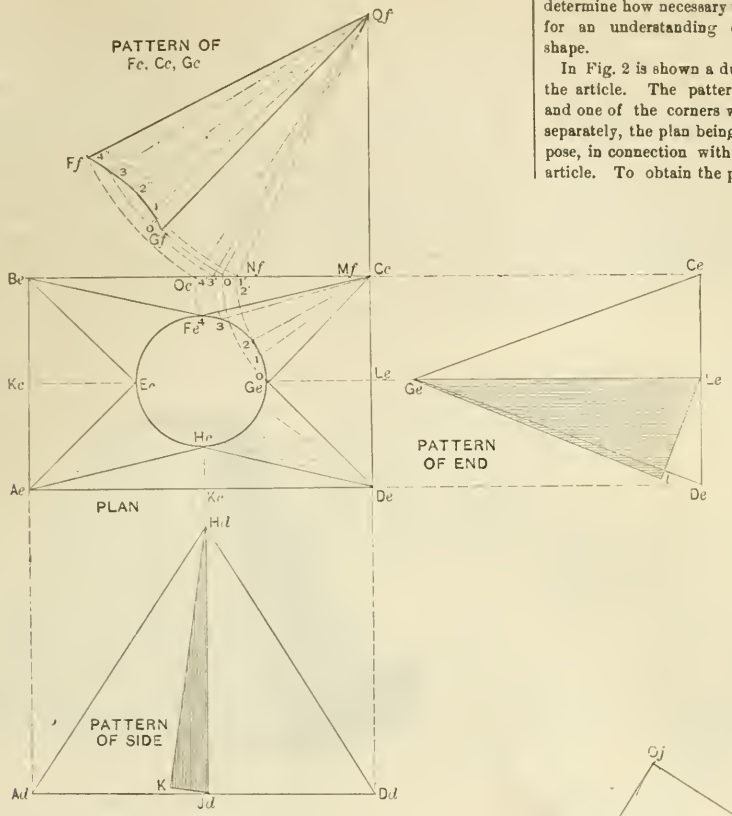

Fig. 2.—Method of Obtaining Patterns of Side, End and Section of Oblique Cone.—Plan Only Used, the Hight of Article Being Known.

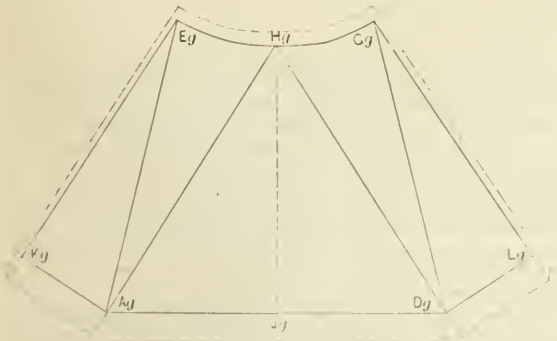

Fig. 3.—Patterns Obtained in Preceding Figure Placed Together so as to Form One-half the Article.

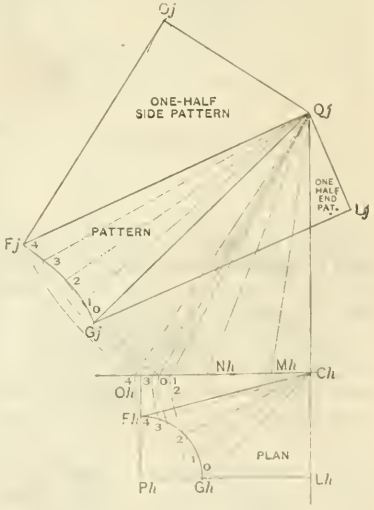

Fig. 4.—Pattern for One-fourth the Article Obtained from the Quarter Plan.

PATTERN FOR CHIMNEY TOP.

points of view can be omitted, as will be shown.

In Fig. 1 let A B C D represent the size of top in plan, and E F G H the opening. Above the plan is shown the side elevation of article, as indicated by Aa is equal to Db Hb of end elevation, as the slant hight of Lb Gb of end elevation is equal to Aa Ea of side elevation. An inspection of the plan will show that the sides of the article are formed of two triangles similar to A H D, Aa Ha Da of side the corners, as Fc Cc Gc, proceed as follows: On Dc Cc extended, set off the hight of article, as shown by Cc Qf. This distance is the same as shown in Fig. 1 by Ja Ha, or Lb Gb. Divide Gc Fc into any convenient number of equal parts, as

indicated by the small figures. With Cc as center, strike arcs from the various points in Gc Fc, cutting Bc Cc, as shown. Also set off from Cc the distances Kc Hc and Dc Kc, as shown by N*f* M*f*. If desired, carry lines from the points thus obtained to Q*f*.

If the triangle M*f* Q*f* Cc was cut out and placed with its base on Kc Hc of plan, the hypotenuse M*f* Q*f* would give the distance from Kc in the base to Hc in the top, as if measured on the finished article. The hypotenuse of triangle N*f* Q*f* Cc gives the distance from point Lc in the base to point Gc in the top. The hypotenuses of the remaining triangles give the distances from point Cc in the base to the various points in Gc Fc of top.

strike small arcs in the direction of Ge, then from the point of intersection draw the lines De Ge, Ge Ce. It is evident the length of side pattern Ge Ce must be the same as G*f* Q*f* of corner pattern, as the two are to join. The triangle N*f* Q*f* Cc is shown with its hypotenuse N*f* Q*f* on Ge Le of end pattern, thus showing that N*f* Q*f* and Le Ge are of the same length. Ge *l* Le is a right angle.

The pattern of side Ac Hc Dc can be obtained in a similar manner. As shown below the plan, A*d* D*d* of pattern is equal to Ac Dc of plan, and the length of J*d* H*d* of pattern is equal to M*f* Q*f* of triangles. The triangle M*f* Q*f* Cc of diagram is shown in pattern by H*d* J*d* *k*, and the hypotenuse H*d* *k* is equal to M*f* Q*f* of diagram.

An inspection of the half pattern in Fig. 3 will show that if we had obtained the pattern of H*g* G*g* L*g* D*g* J*g*, the other part, as indicated by H*g* J*g* A*g* K*g* E*g*, could be marked from it, or the quarter pattern could be used for marking off the whole of pattern, if the article was to be made in one piece.

In Fig. 4 is shown a method for obtaining the quarter pattern for the top, in which much of the drawing previously shown has been dispensed with. To describe the pattern, draw any line, as Q*j* L*h*, indefinitely. Erect the perpendicular C*h* O*h*, and from C*h* set off the half width of end. Draw L*h* P*h* parallel with C*h* O*h*. From C*h* set off the half width of side, as shown by C*h* O*h*. Draw O*h* P*h* parallel with C*h* L*h*. With P*h* as

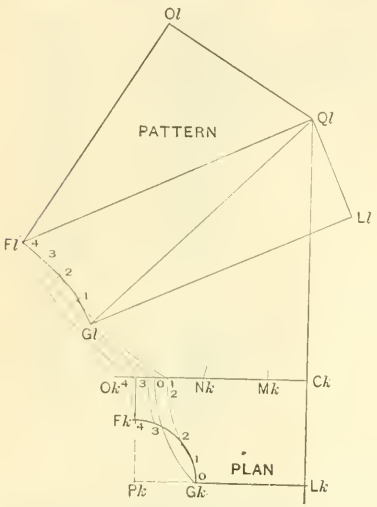

Fig. 5.—Same as Preceding Diagram with Unnecessary Figures Omitted.

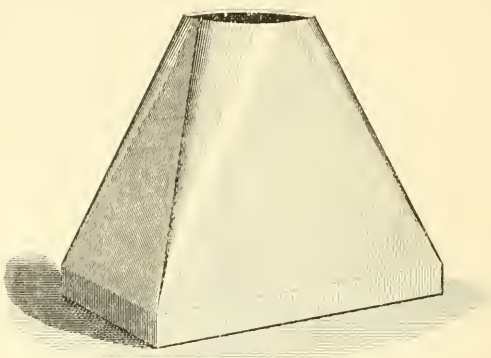

Fig. 6.—The Finished Article.

PATTERN FOR CHIMNEY TOP.

With Q*f* as center, strike an arc from the point *o'* and draw the line G*f* Q*f*, which is the distance from point Cc in base to point Gc in top. With Q*f* as center strike arcs from the points 1', 2', 3', 4', and with the dividers set to the spaces in Gc Fc of plan, and starting from point *o''* G*f*, space off the stretchout of Gc Fc, stepping from arc to arc, as indicated by the small figures 1'' to 4''. Draw the line F*f* Q*f*, and trace a line free hand through the points in F*f* G*f*, as shown. Then G*f* F*f* Q*f* is the pattern for part of article shown on plan by Ge Fc Cc.

For the pattern of end Dc Gc Cc, proceed as follows: Draw any line, as De Ce, in length equal to Dc Cc of plan. Bisect this line and erect the perpendicular Le Ge, in length equal to N*f* Q*f* of diagram, and draw the lines De Ge, Ge Ce. Then De Ge Ce is the pattern for end of article shown on plan by Dc Gc Cc.

Another way of obtaining this pattern would be by drawing the line De Ce, as previously directed, and with Q*f* *o'* as radius and the points De and Ce as centers,

We will suppose the pattern for the article is to be described in such a manner that two pieces will make the article. Also that the seams are to be at the ends, as indicated by Kc Ec, Gc Lc of plan. This pattern is shown in Fig. 3. A*g* H*g* D*g* is a duplicate of A*d* H*d* D*d*. The pattern of G*f* F*f* Q*f* could be cut out of some convenient material and used to mark off D*g* H*g* G*g* and H*g* A*g* E*g* of Fig. 3, or the pattern for these parts could be obtained in the same manner as shown in Fig. 2. For the pattern of the half ends, proceed as follows: With D*g* and A*g* as centers, and De Le of plan as radius, strike small arcs L*g* K*g*, and with G*g* and E*g* as centers, and Ge De as radius, strike other small arcs intersecting the ones just struck. From the points of intersection draw the lines G*g* L*g*, L*g* D*g* and E*g* K*g*, K*g* A*g*. Or, the duplicate of Ge Le De can be used for marking off the half pattern of the ends. The allowance for laps and for going over the top of chimney can be made as indicated by the dotted lines, or as desired.

center, and the compasses set to the desired radius for size of pipe or opening in top, strike the arc F*h* G*h*. Divide this arc into any convenient number of equal parts and draw lines to C*h*. With C*h* as center, strike arcs from the points in F*h* G*h*, cutting O*h* C*h* as shown. Make Q*j* equal to the hight of article, and from the points in O*h* C*h* draw lines to Q*j*. With Q*j* as center and the points in O*h* C*h* as radii, strike arcs as shown. From any convenient point, as G*j*, draw the line G*j* Q*j*. Set the dividers to the space used in stepping off the arc F*h* G*h* and, commencing at the point G*j*, step to the second arc and from that point to the next arc and so on, reaching the last in the point F*j*. Draw G*j* F*j* Q*j*. From C*h* set off the distances O*h* F*h* and L*h* C*h*, as shown by M*h* N*h*. Draw lines from these points to Q*j*. With Q*j* as center and C*h* L*h* as radius, describe an arc, L*j*, and from G*j* as center, with radius equal to N*h* Q*j*, intersect the arc L*j*, as shown. Draw G*j* L*j* and L*j* Q*j*. In a similar manner, with F*j* as center, and Q*j* M*h* as radius, describe the arc O*j*, and

from Q*j* as center, with a radius equal to C*h* O*h* of the plan, intersect the arc at the point O*j*. Draw Q*j* O*j* and O*j* F*j*.

An inspection of Fig. 4 will show that the lines in C*h* G*h* F*h*, O*h* Q*j* C*h* and the dotted lines in F*j* Q*j* G*j* are not necessary for the development of the pattern, but are used for convenience of illustration. The pattern can be obtained as shown in Fig. 5, thus dispensing with the drawing of ten lines. The allowances for laps can be made about the quarter patterns in Figs. 4 and 5 as desired, or as indicated in Fig. 3.

The finished article is shown in Fig. 6.

Relative Cost of Gas and Electricity.

In an able article, published under the above heading, in the *Engineering Magazine*, C. J. Russell Humphreys discusssses the cost of lighting by electricity as compared to that of gas, a question which has been much agitated with varying conclusions during recent years. Mr. Humphreys evidently approaches the subject with ample knowledge of all its details; and his article is a most exhaustive treatment of the question. He marshals therein a long array of facts and figures relative to the output and expenditure of gas companies and electric light companies, from which he draws his deductions. Comparing facts and statistics obtained from official documents and by personal observation and calculation, the writer reaches the conclusion that for the present electric lighting is more costly than gas lighting, although the future may possibly reduce the cost of the former by the development of cheaper "handling," if we may so term it, of electricity.

Mr. Humphreys' paper is of such general interest that we present a summary of it, with extracts, for the benefit of our readers:

"We are told that one gas acts as a vacuum to another, and so it has seemed in the lighting business. Though the world has absorbed in a vast amount the newer illuminant known as electricity it does not follow that the use of gas has decreased to a corresponding degree. On the contrary, more gas has been used year after year, showing that the world is finding use for a larger amount of artificial light.

"A glance at night along the main thoroughfares of any large city will show a vast increase in the amount of light used as compared with a period of 20 years back. Much lighting is done now purely for advertising purposes. It no longer suffices to have a store lighted so that salesmen and customers can find their way around, before and behind the counters, and stop at that: the whole interior of the shop, and the exterior as well, must be flooded with light, and whether the lighting agent be gas or electricity, it must be of high intensity and in large volume. The effect of this is far-reaching, for the merchant who grows used to bright lights in his store or counting room insists on having a great deal of light at his home. Nor is this all. In days gone by it would suffice if the streets were lighted with lamps few and far between, but now they must be lighted in the fullest meaning of the term. Again, the tendency in recent years to erect sky scraping buildings, which shut off the natural light from the smaller edifices and the lower stories of the larger ones, entails the use of vastly increased amounts of artificial light during that portion of the 24 hours when Old Sol was once supposed to do all the lighting business. Thus it happens that this large receptive capacity of the world for artificial light has led to the building up of a large business for the electric light corporations, without by any means snuffing out the older illuminant.

"In support of this assertion it can be shown than in 1891 the gas companies of Massachusetts made 20 per cent. more gas than in 1889. This showing is the more remarkable when we consider the business done by the electric lighting companies of the same State. The figures for 1891 show that the gross receipts of these companies were equal to 45 per cent. of the gross receipts of the gas companies, a statement which is at once a testimonial to the energetic manner in which the electric lighting business has been pressed, and evidence of the increasing demand for artificial light. To illustrate the latter tendency in another way, it may be shown that in the same State, during 1889, the capacity of the incandescent electric light companies aggregated 84,400 lights, reduced to the standard 16-candle lamps, whereas in 1891 the figures had grown to 183,120 lamps. During the same years the capacity of the arc light stations increased from 11,529 to 15,338 lamps."

The question is then asked, "Is this growth to hold for the future, and how will it affect the sale of gas for lighting purposes?" The answer depends largely upon the relative cost of gas and electricity. To obtain this cost Mr. Humphreys reduces his figures to a common standard for the two illuminants—namely, 16-candle light—and then considers the relative amount of capital required in each business per unit of light, and the percentage of gross receipts in each case required to pay the expenses of manufacture and distribution.

The capital required by an electric light company engaged in central station lighting—that is, supplying light to a large number of customers from a central station—is shown to approximate $30 per dynamo capacity of the station, reckoned on a basis of a 16 candle light. The capital required for 1000 feet of yearly output of gas is estimated at $6. Reducing these figures to the basis of a lamp-hour—that is, of 16 candles for one hour—calculation shows the capital required per 16-candle lamp-hour output to be as follows:

For electric light.....3.6 cents.
For gas, on same basis.....2.6 cents.

According to which the electric lighting plant requires 40 per cent. more capital for doing a given amount of business.

In comparing the relative cost of manufacture of gas and electricity and expressing the same in percentage of gross receipts, the receipts and expenditures are reduced to the common 16 candle lamp-hour standard, with the following result:

	Per cent.
Cost of gas in percentage of gross earnings.....	71
Cost of electric light in percentage of gross earnings from equal unit of light.....	91

or, otherwise expressed, the unit of light costs by electricity 20 per cent. more than by gas.

It is thus found that, in order to obtain the unit of light from gas or electricity, we must invest 40 per cent. more capital in the electric business than gas, and the cost of making the unit of light will cost by electricity 20 per cent. more than by gas, as expressed in percentage of gross receipts of the latter. And, as the earning of a 6 per cent. dividend on the capital invested requires in the case of gas an amount equal to 26 per cent. of the gross earnings, and as the capital required in the electric business per unit of light is 40 per cent. greater than in the gas industry, it follows that in order to obtain a profitable investment from the electric business we must obtain for a dividend an amount equal to 36 per cent. of the gross earnings from gas. That is, if A = gross receipts from gas per unit of light, then we must obtain for electric light: (A + 91 per cent) + (A + 36 per cent.) or 127 per cent. of the price of gas, which simply means that if gas sells for $1 per 1000 feet, the selling price of electricity for an equivalent light must be $1.25.

That this is the practical result so far is evident from the fact that, as before noted, the receipts from electricity per unit of light are about 28 per cent. greater than from gas.

The writer, in conclusion, remarks that his observations have been strictly confined to the conditions that actually obtain to-day in the case of gas and electric lighting. He does not discount the future, and figure on the possibilities of reducing the cost of electricity on the one hand by improvements in the steam engine, or on the other by the possibilities before the gas engineer in converting the energy of the gas into light; remembering that by our present wasteful method we actually utilize but a scant 8 per cent. of the energy of gas in burning it.

After all, the question resolves itself into one of economy in coal consumption; and in the long run that system of illumination will predominate which gives out in the form of light the greatest percentage of the energy of that substance which we are too apt to squander so thoughtlessly—coal.

According to statistics gathered by the *Puget Sound Lumberman* for the year 1892, the cut of lumber of Washington shows a decrease over 1891 of 214,000,000 feet. This is accounted for by the subsidence of the building boom of 1890-91, causing a shutdown of many mills on Puget Sound. Meanwhile the cargo trade done in 1892 in foreign and coastwise shipments exceeded the figures of the previous year by 50,302,933 feet, while the rail shipments show an increase amounting to 20 per cent. The most marked feature of advance has, however, been in the growth of the shingle trade. With 127 new shingle mills the increase of shipments amounted to no less than 311,068,000 shingles in 1892 over 1891, and the mills are stated to be behind with orders, owing to not being able to get sufficient cars to ship the material.

The Detroit Foundry Equipment Company have established a Foundrymen's Exchange at 225 Dearborn street, Chicago, with a view to diffusing knowledge of the industry, through printed matter, and to bring into closer touch those engaged in the foundry business generally. It is suggested that this step may possibly lead to the formation of a permanent foundrymen's association such as exists at Philadelphia, and which has proved so popular and from which so much good has resulted. Newspapers, journals and reading matter of a popular and technical nature are on file in the club room, which is open free to those interested for study and social intercourse.

Shares of numerous trust companies formed in England a few years ago, when a mania for this sort of enterprise was prevalent, are now either greatly depreciated or wholly unsalable. The London *Economist* says: "Week after week evidence accumulates, proving only too forcibly that those responsible for the management of these trusts have based no inconsiderable part of their operations upon false principles, with the inevitable result that, after a more or less brief period of apparent prosperity, losses and difficulties have arisen, and unless greater foresight and ability is displayed in the future than has been shown in the past, it is highly probable that collapses of a disastrous kind will take place."

STEAM AND HOT WATER.

Steam Hot-Blast Apparatus.

BY WALTER B. SNOW.

What is familiarly known as a steam hot-blast apparatus, or blower heating apparatus, in its complete form always comprises at least three elements—a fan, for producing movement of the air; a steam heater, for heating the air thus set in motion; and a motor, for driving the fan either by direct connection or through the medium of a greater or less amount of belting and shafting.

FORMS OF FANS.

Fans are varied in their forms and uses, but may all be classed under two general heads—the disk or propellor fan and the paddle or peripheral discharge fan.

Of the two, the former is probably the more familiar, employed as it is so generally in its character of electric fan, with its blades of brass, scarcely visible at the high speed it is run to produce a refreshing breeze on the hot summer day. Much ingenuity has been displayed, and the higher mathematics often employed, in the design of the numerous forms of disk wheels now upon the market.

The simplest of all types consists of a wheel of six or more radial blades set at an angle of 45° with the shaft, and acting as inclined planes to force the air in a direction parallel to the shaft. A simple yet somewhat more elaborate form is shown in Fig. 1, the outer ends of the blades being curved over and attached to the concentric ring which binds them all together. This curvature serves to prevent any possible radial discharge, and also presents an extremely satisfactory manner of building the wheel.

Surprising results have been obtained by a wheel consisting merely of two radial arms, upon the extremity of each of which was attached a thin blade about the size and shape of one's hand. When properly formed into shape and set at the proper angle to the shaft, such a wheel will discharge a solid volume of air in a direction so nearly parallel to its shaft that at a distance of 15 feet the circumference of this moving cylinder of air is distinctly discernable by the hand.

The paddle or peripheral discharge fan is illustrated in its most common form in Fig. 2. The blades are all radial and flat, although to accord better with theory, while producing scarcely better practical results, they are frequently made curved, the convex side being presented to the air. The curving of the blades, however, is desirable when noise is to be avoided. A somewhat more efficient form of this wheel has a cone or conoid in each of its inlets, the axes of the two being formed by the shaft and their bases meeting upon a plane in the center of width of the fan and at right angles to the shaft. The air as it enters the inlets of the fan is thereby gradually changed in its direction of movement until it leaves the blades radially.

In this latter type of fan the two inlets are frequently connected to some pipe or space from which the air is to be drawn, and the air is discharged freely all around the fan periphery into the apartment in which the fan is located. The simple type of paddle fan is, however, almost universally incased in a shell having inlets corresponding to and concentric with those in the wheel and an outlet properly placed somewhere upon its circumference. Such cases were originally constructed of cast iron, being expensive and bulky. The adoption of sheet iron, properly braced, as a fan casing, practically revolutionized all designs in ventilating fans driven at low speeds.

The popular form as now manufactured is represented in Fig. 4, in connection with a heater. Fans of this description can be readily built 15 feet to 25 feet high, a practical impossibility with cast iron.

THE HEATER.

The duty of the heater in a steam hot-blast apparatus greatly exceeds that of any form of radiator under any other conditions. The extremely large volume of air brought in contact with the pipes and its rapid cooling effect when taken directly from out of doors on a cold winter's day, produces within the heater the most rapid condensation and the greatest extremes of temperature, expansion and contraction.

Among the earlier forms of heaters applied in connection with the last described type of fan was the tubular variety, in arrangement similar to a tubular boiler on a small scale, consisting simply of a cylinder with a head at either end and a series of connecting copper or brass tubes expanded therein. Steam, either live or exhaust, was admitted to the space around the tubes and inside the cylinder while the air was rapidly drawn through the tubes by the blower and forced through a system of piping to its destination.

As the field broadened, this form of heater became inadequate to fill all requirements and the sectional base heater was evolved, being in fact nothing more than a steam pipe radiator specially constructed for use in connection with a fan.

This form of heater requires :

1. That the pipes shall, for economy of space, be as compactly arranged as possible.

2. That they shall, for efficiency, be far enough apart to prevent serious obstruction to the flow of air to or from the fan.

3. That they shall be so arranged as to most thoroughly break up the currents of air and cause every particle to impinge upon the surface of the pipes in its passage through the heater.

4. That the pipes shall not be too long for the effective condensation of the steam.

5. That the area for steam passage through the pipes shall be such as to place no objectionable back pressure upon an engine supplying exhaust steam to the heater.

6. That, as in the case of all sectional radiators, these sections shall be capable of being readily made up into groups and inclosed in housings through which the fan can force or draw the air.

Of course, as in all radiator designs, the questions of expansion, weight of sections, convenience of handling, durability and cost must also enter in.

With the extremely rapid condensation taking place in a steam hot-blast apparatus, long pipes are to be avoided, particularly with exhaust steam; in the coils first exposed to the cold air in its passage through the heater the steam is so rapidly condensed as to travel but a short length of the pipe before becoming water. For this reason the trombone coil type of heater, when in large sizes with only a single inlet and drip for each coil, becomes inefficient and a multiplicity of inlet and drip manifolds becomes a necessity in order to reduce the distance the steam must flow. This type of heater is, however, quite generally used in the form shown by accompanying cut, Fig. 3.

The most common and convenient form of heater is constructed of rows of vertical pipes screwed into cast-iron bases. The end pipes are the highest and gradually decrease in length toward the center of length of the base. The top of each pipe is elbowed, and connection with its corresponding pipe upon the other end of the row is made by a horizontal cross pipe. The cast-iron base is cored and divided midway of its length by a diaphragm. Steam admitted to one end of this section can therefore reach the other end only by passing up, over and down the pipes—no one pipe being of excessive length. Such sections are usually built in sizes 3, 4, 5, 6 and 7 feet in length with the respective hights of 4, 5, 6, 7 and 8 feet, so even in the 7-foot section the greatest length of pipe cannot be over 22 feet through which the steam must pass from one end to the other.

Drainage of water of condensation from the end of the base to which steam flows is accomplished by any of the well-known devices of traps or float valve receiving tanks. These sections are usually constructed with two or four rows of pipe to a section, rendering them easily portable and making it more feasible to combine than in heaters of various capacities.

HOT-BLAST APPARATUS.

Two different forms of steam hot-blast apparatus are shown in Figs. 3 and 4. The former represents a disk wheel forcing air through a heater of the trombone construction. The entire heater is incased in the sheet-iron jacket and steam and drip connections made as shown. The fan forces the air directly against the pipes, whence it passes to the further end and is either discharged directly into the room or, by means of a system of sheet-iron piping, connected to the end of the heater case, is conducted in the required proportions to the various apartments to be heated. The entire apparatus is mounted upon a wooden platform, which renders it portable. While such a type of fan is usually of necessity driven by belt on account of the high rotative speed required, a steam engine is sometimes directly connected to the fan shaft, as here shown, and supported upon a special cast-iron bed.

The advantage of a direct connected, or, at least, a special engine for any steam hot-blast apparatus must be evident. It renders the heating system independent of the remainder of the motive plant in a manufactory; makes it possible to run the apparatus at any and all times independently of any other engines or machines, and allows of an instant change in speed to meet any conditions. Unless there is already an abundance of exhaust steam to be utilized, the cost of running the fan is hardly to be considered, as all of the ex-

haust of the fan engine will be condensed in the heater and pound for pound will be practically as efficient as live steam for heating, but will only require a larger condensing surface.

Fig. 4 represents the general construction of a steam hot-blast apparatus, with cased fan and sectional heater. The fan is constructed of sheet iron, its method of bracing being plainly shown. In large sizes this type of fan is sometimes constructed the end of its extended shaft, and will thereby avoid a bearing in the inlet of the fan upon the opposite side from that upon which the engine is placed.

POWER FOR FANS.

Where high speed of fan is desirable with a direct connected engine, a double-cylindered short stroke engine capable of high rotative speed is often employed, and with its two well spaced journal bearings, easily supports the fan wheel upon the shaft end.

The heater shown in Fig. 4 has its cast-iron bases so constructed that steam can be admitted to their upper portion, while a passage beneath, connecting with the further end of the section, serves to drain the water of condensation. The sections, supported upon an angle iron frame with ball bearings to allow for expansion, are bolted together by through bolts, with gaskets between the sections, so that a single inlet or drip serves for the group. The arrangement of the heater pipes is at least hinted at by the small section where the jacket is shown broken away in the upper corner of the heater.

Air enters the heater at the open further end, which cannot be seen, and is drawn in an even volume across the pipes to the inlet of the fan, which is connected with the heater jacket, and is discharged from the fan outlet into any desired system of distributing ducts.

Steam hot-blast apparatus of either type

STEAM HOT-BLAST APPARATUS.

so that only the upper portion is of sheet iron, the lower portion, just including the hight of the outlet, being formed of brick in the foundations and the air duct carried beneath the floor. Of course the same general construction may be employed when the fan is to discharge in any other direction. With this type, known as the "three quarter housing," a horizontal engine must be substituted for the upright shown in the cut. Various types of upright engines are employed with the full-housed fans. One, with two journal bearings, will serve to carry the fan wheel upon

here illustrated may be operated with either live or exhaust or with live in one position and exhaust in the other. The fan velocity may be varied at will with a direct-connected engine, but seldom is run over 1 ounce air pressure, corresponding to a velocity of the circumference of the fan wheel of nearly 1 mile a minute.

The electric motor is fast becoming a rival of the steam engine in fan propulsion, and, when of first-class design, has many points of advantage with a practically constant speed and load. For the non-mechanical man, it is much easier to

start up a motor by turning a switch than to start up an engine with attendant care of drips, oil cups and bearings.

Destruction of Pipes by Condensed Steam.

From E. S. & S., *Arbor Springs, Mich.*—We are troubled with our steam-heating pipe being eaten up by the soft water condensation of steam. In our system no water is returned to the boiler, the exhaust from the pumps heating the feed water to the boiler. We use steam from waterworks boiler to heat residences, shops, &c., and at some distance away—one 500 feet, another 300 feet and two shops about 200 feet distant. Where there is a cinder welded in the pipe holes soon appear and we have been obliged to take out as many as eight pipes during one season. Is there any way to prevent it?

Note.—The trouble mentioned by our correspondent is a very general complaint from those who have to handle the water of condensation in underground pipes. A great deal of trouble from this cause was experienced in New York, the return pipes which carried the pure water back to the main heating plant corroding very rapidly. We have also heard of similar difficulty in other cities, and so far as we know, no remedy has been suggested. If any of our correspondents have met and overcome this trouble, we should like to know how they did it.

HEATING NOTES.

With a view to bringing about the organization of the contracting master fitters of the State of Michigan, a general call was issued for a meeting to be held at Detroit, on Wednesday and Thursday of this week. The call was signed by Webster & Meath, Detroit; Sproul & McGurrin, Grand Rapids; Wheeler & Pitkin, Kalamazoo; Watson & Tossell, Bay City and Charles W. Light, East Saginaw. Secretary George H. Reynolds of the National Steam and Hot Water Fitters' Association was to be present in the interests of organization, and it was hoped that President Hudson would likewise be there.

The Raymond & Campbell Mfg. Company, Middletown, Pa., have just completed arrangements with the following well known houses, for handling their Sun boiler: Timmins & Manning, Boston; Baker, Smith & Co., New York; E. C. Shaw & Co., Philadelphia, and the Brewster Hardware Company, Raleigh, N. C. The terms of the agreements cover a period of five years.

Charles E. Wakeman, Pontiac, Mich., has secured a patent on a new form of steam heater. The features of this apparatus include a special arrangement whereby more perfect and uniform combustion is secured and the heating surface greatly increased in proportion to the volume of water.

The J. L. Mott Iron Works, 311-313 Wabash avenue, Chicago, are to place one of the Sunray hot water heaters in the Chicago & Northwestern Railway depot at Oak Park.

The Smith & Anthony Stove Company, 219 Lake street, Chicago, have the contract for the steam heating of the Hull House, Chicago's famous philanthropic institution.

The Wells & Newton Company, 1108-1109 Monadnock Block, Chicago, do the steam heating of the Marshall Field building, Art Institute building and Chicago Beach Hotel.

Prize Competitions

$25.00.

In order to obtain information which will be of practical service to our readers we hereby announce

Prize Competition No. 16.

subject:

Three or More Rules to be Observed in Buying.

This competition will remain open until April 8, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received

Replies are to be received not later than April 8, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96-102 *Reade street,*
New York.
Prize Competition No. 16.

The committee to whom the contributions in Prize Competition No. 2 were referred have awarded the prizes as follows:

First Prize to M. W. Carleton, Cleveland, Ohio.

Second Prize to F. F. Gilmore, Louisville, Ky.

Third Prize to Walter Eikel, Chihuahua, Mexico.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 13. Closing March 18.
The Best Method of Changing a Credit into a Cash Business

No. 14. Closing March 25.
Suggestions Regarding the Sale of Spring and Summer Goods.

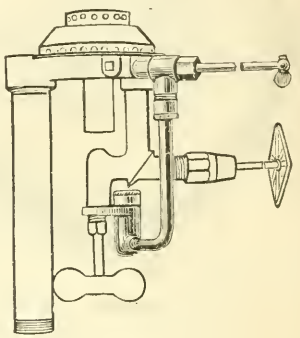
No. 15. Closing April 1.
Suggestions in Regard to the Sale of Athletic and Sporting Goods.

No. 16. Closing April 8.
Three or More Rules to be Observed in Buying.

Another subject will be announced in our next issue.

Attachment for Gasoline Stoves.

An attachment for starting gasoline stoves has just been patented and is being introduced to the trade by H. E. Borzell of 1943 Germantown avenue, Philadelphia, Pa. The construction of this device is claimed to be such as to render an overflow impossible; while the burner on top can be kept always ready for use, thereby preventing all danger of the clothes catching fire. It is also stated that its employment does away entirely with the use of cups. It lights like a candle and can be



Attachment for Gasoline Stoves.

applied, it is said, to any gasoline stove at a nominal cost. A good idea of the construction and arrangement of parts may be gathered from an inspection of the engraving presented herewith.

Scrap.

Franklin Rudolph, Chicago, Ill., has secured a patent on a process for manufacturing tin plate. The articles to be treated consist of sheets of black iron or steel, coated on one side only with tin. The patentee points out that such a material would be useful, among other purposes, for roofs, trunk covering or tin cans. The chief feature of the process is to treat two sheets at a time, so that only one surface of each sheet is exposed to the coating metal.

Albert Hatten and W. J. Stone of Binghamton, N. Y., have opened an establishment for all kinds of sheet-metal work, tin and iron roofing, gutters, eave troughs, cornices, conductors, ridging, &c., for building purposes. Both men have been active in business at Binghamton for years, and have many friends who wish them success.

A Minneapolis journal says the outlook for the spring season in the Northwest is not at all favorable. It is many years since the country has been covered with so deep a body of snow as now covers it, and this is a guarantee that roads will be bad when the break up comes. For several weeks the roads have been in an almost impassable condition, and the prospects are that when the spring season sets in things will be unpleasant for the country merchants unless the sun is strong enough to hasten the break-up of the snow.

The Maris Hand Traveling Crane.

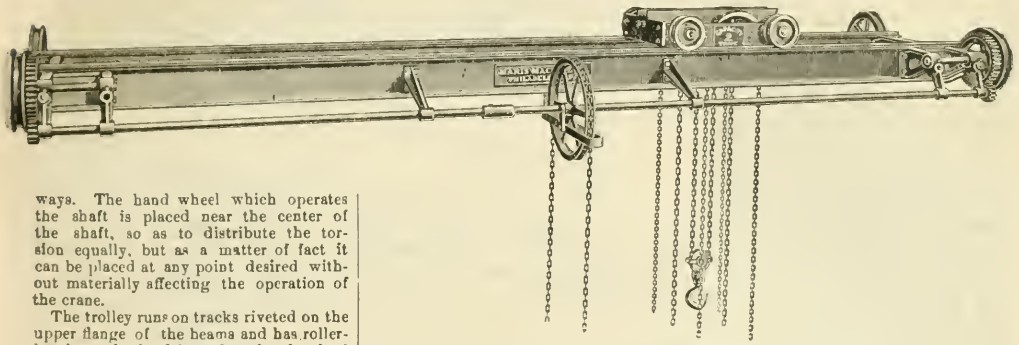
This crane was originally designed to meet the requirements of general machine shop use, and especially in those places where the infrequency of use of such a machine prohibits the employment of power cranes.

The bridge of the crane is constructed of two steel I beams of proper section to give ample strength and prevent undue deflection when the load is in the center of the span. To these are bolted at each end separators on the inside and truck brackets on the outside. A wrought-iron tie rod extends from the outside of the wheel bearing on one side, under the beams to the outside of the wheel bearing on the other side—thus bringing the tensile strain on the wrought iron and the compression strain on the cast iron.

The truck wheels have roller bearings working in steel bushings and are driven at equal rates of speed on both ends of the crane, by a shaft running across the span of the bridge, carrying on each end a pinion which gears into the wheels, thus keeping the crane straight on the runways. The hand wheel which operates the shaft is placed near the center of the shaft, so as to distribute the torsion equally, but as a matter of fact it can be placed at any point desired without materially affecting the operation of the crane.

The trolley runs on tracks riveted on the upper flange of the beams and has roller-bearing wheels driven by a hand wheel mounted in the trolley itself.

The hoist is mounted in the trolley and does not hang underneath it unless specially desired. This arrangement gives the greatest possible lift and, together with the small amount of head room taken up by the trolley, makes the crane very economical of space. These cranes are made by Maris & Beekley of 2343 Callowhill street, Philadelphia, in all sizes from 1000 pounds up.



THE MARIS HAND TRAVELING CRANE.

World's Fair Hotel.

R W. Montross, manufacturer of specialties at Galien, Mich., and H. W. Coolidge, who has been identified with the wholesale Hardware trade at Chicago for 20 years, will conduct a hotel on the European plan, named the Audubon, on Oglesby avenue, near Midway Plaisance, only four blocks from the main entrance to the World's Fair. These gentlemen first conceived the idea of entertaining their own friends and customers, so as to supply them with inexpensive but good accommodations, but afterward decided to increase the scope of their plan. The scale of prices may be of interest. One-half of the house, containing 50 rooms, is rented by the room at $3 to $6 per day per room, while the other half is rated per person at from $1 to $2 per day. These rates are subject to change as the season advances, and of course do not include meals. A *café* will be conducted in the hotel for the convenience of the patrons. The proprietors require reference from applicants not personally known to them who make advance engagements. The hotel will be directly under the management of N. H. Henchman, Jr., an experienced and widely known hotel manager. Souvenir catalogues and further information can be obtained by addressing Montross & Coolidge, Room 1433 Masonic Temple, Chicago.

Ventilation.

The following article, which treats of ventilation in a very simple way, was prepared by D. H. Smith, Watkins, N. Y., to present the subject to a few country school trustees and teachers, all technicalities being purposely avoided:

Ventilation may be simply defined as a process of supplying pure air to a room and getting rid of the impure air at the same time. Ventilation and warming must necessarily be considered together, as artificial ventilation, without the use of machinery, must be accomplished by means of heat. Natural ventilation may be obtained by opening windows in opposite sides of a room. Pure air will come in at one opening, and the vitiated air will go out of the other, according to the direction of the air currents outside. This form of ventilation will do in summer, but not when the outer air is too cold to be brought into the room. This fact must always be remembered—that a room always contains the same volume of air. It is full. You cannot increase the quantity, neither can you diminish the volume. Therefore, if air is taken out of a room by any device, and no special opening is provided for the ingress of pure air to replace that taken out, the air must come in as best it can through crevices in the windows and doors. On the other hand, warm air will not come into a room through furnace pipes any faster than air can escape from the same room. This is the reason it is so hard sometimes to warm a dwelling with a warm-air furnace when there is no ventilation.

It is a wise law of nature that the most impure and coldest air is at the floor of a room. The purest and warmest air is near the ceiling. House ventilation should be planned to get rid of the cold and impure air, and in this way ventilation will assist in the heating, by getting the cold air out of the way and allowing the warm air from the ceiling to descend and warm the room. A room is always warmed from the top downward, the warm air from whatever source rising at once to the ceiling and settling down as it is cooled. It is also important that the pure air which is introduced into a room to take the place of the air sent out should pass over a heated surface of some kind on its way, so as to come into the room warm.

The fact that air when heated will rise and when cooled will fall is taken advantage of to effect ventilation. Flues may be properly built and openings properly made, but the air within the flue will be as likely to descend as to rise, if it is not artificially warmed. Any flue in the wall, having an opening at the floor into a room and extending up through the roof, will make a ventilating flue, if the air within the flue is warmed in some way. A good way is to construct a chimney with two flues, one for the smoke flue of the heating apparatus, the other for ventilation. The heat from the smoke flue will warm the ventilating flue, so that the air within the flue will rise and escape, and, of course, draw the air from the room through the opening at the base. A still better way is to build a large chimney (12 x 20 inches inside is about right for a large country schoolhouse) and use a cast-iron smoke pipe 8 inches in diameter, placed inside the flue when it is built and extending to the top. The space inside the brick flue and surrounding the smoke pipe makes one of the best ventilating flues known, as the cast smoke pipe will warm the air in the flue much more than one side of a brick flue possibly can. Leaving out of consideration the large heating and ventilating apparatus, too costly for general use, the best schoolroom heater is a warm air furnace of suitable size. This heater can be set up in one corner of the room out of the way, no matter where, if smoke flue is near. It should be set a few inches above the floor with a case open at top and bottom. When in operation the air inside of the case becomes heated and rises to the ceiling and the cold air is drawn in at the bottom, and this circulation will continue as long as there is fire in the heater. This circulation is not ventilation; not a bit of it. The temperature in all parts of the room, at same hight from the floor, will be the same whether the room is warm enough or not. When the room is warm scholars close to the heater will not be too warm, and those in distant parts of the room not too cold, as is the usual way.

To complete the arrangement properly there should be a ventilating flue suitably warmed, and also a cold-air flue of the same size from the outer air brought with the opening directly under the heater. Then the air which comes into the room to take the place of the foul air sent out through the ventilating flue, will come in warm as it should, instead of coming in cold through the crevices of doors and windows.

ROOFING AND CORNICE.

Kanneberg's Patent Folded Lock Seam Steel Roofing.

The Kanneberg Roofing Company of Canton, Ohio, are introducing to the trade a patent folded lock seam steel roofing, which we understand is meeting with much satisfaction. In the making of the seam a patent cleat is employed, the holding power of which is not only its full width, but a tongue which hooks over an inch flange avoids, it is stated, the bending down process. Another feature to which attention is invited is that the pressure of the tools in forming the seam forces the tongue against the flange over which it is hooked, indenting it into the aperture of the cleat, thus practically locking it in place. In Fig. 1 of the illustrations is shown a view of the cleat or fastening, which is made of Bessemer steel, and is 2 inches high by 2¼ inches wide. Fig. 2 shows a 1-inch flange, A, turned up on the roof, the tongue B of the cleat being hooked over it and the foot of the cleat secured at C to the sheeting boards. Fig. 3 shows another step in the construction of the seam. The 2¼-inch flange D of an adjacent sheet is turned up on the roof and placed against the back of the cleat and of the 1-inch flange A of the sheet in contact with it. The next step in the work is shown in Fig. 4, which represents a ¼ inch hem, E, seamed over the top of the cleat, while in Fig. 5 the upper half of the unfinished seam is turned over the 1-inch flange, thus completing it. The finished seam is shown turned back in Fig. 6, for the purpose of indicating the manner in which the tongue B when the seam is being formed presses against the flange A, indenting it into the aperture of the cleat and locking it in place.

KANNEBERG PATENT FOLDED LOCK-SEAM STEEL ROOFING.

FLASHINGS.

The Perkins patent double plate rolling and swinging shutters and doors is the subject matter of a circular which is being distributed by the Borden-Swearingen Shutter & Iron Works, Kansas City, Mo. Accompanying it is also a circular illustrating iron crestings, finials, expanded conductor pipe, &c.

The Pedlar Metal Roofing Company of Oshawa, Ontario, are distributing to the trade cards illustrating some of their sheet metal specialties. The goods shown include steel pressed brick, corrugated iron, the Pedlar metal shingles, crimped iron, cave trough and metal ceilings. It is said of the latter that the company make 15 styles.

The Kanneberg Roofing Company of Canton, Ohio, favor us with a neat circular, printed in colors relating to the metal roofing and siding which they manufacture. Illustrations are given of Cushman metallic shingles, which are claimed to be quickly and easily laid, crimped-edge iron, corrugated iron, sheet-steel pressed brick, iron weather boarding and cave trough and conductor pipe.

The St. Louis plant of the American Roofing Company has been fitted with new machinery for the purpose of increasing and improving their product. The firm are now very busy in all departments, and their Cincinnati branch will soon be in shape to receive orders for any quantity of sheet-metal material.

John L. Eichberg of Memphis, Tenn., is distributing to his friends in the trade a souvenir in the shape of a medal made of aluminum. It is designed as a pocket piece, and carries upon one side a list of the specialties manufactured by Mr. Eichberg, while upon the other side is brief reference to the metal aluminum, and some of its peculiarities. In the centre of the medal, on a circular panel $\frac{5}{16}$ inch in diameter, is the Lord's Prayer. Mr. Eichberg states that aluminum is used for a great many purposes, and is especially adapted in its alloy form for valleys, gutters, pipes, &c. Mr. Elghberg is also agent for the Bennett & Peck and Rutan & Smead systems of heating and ventilation, as well as for the Aluminum Alloy Metal Company's valleys, gutters, &c.

The Lloyd Iron Roofing & Paint Company, 99 and 101 Monroe street, Chicago, have at last succeeded after a long series of experiments in perfecting a special machine for the manufacture of an imitation of black Spanish tiling in large sheets, for which patents were secured some time since by F. E. Sagendorph, manager of the company. The perfection of the necessary machinery now enables the company to offer to the trade this new product in any quantity desired in large sheets. The difference between this tiling and that heretofore manufactured by others is that the Lloyd tiling can be furnished in sheets 4 and 8 feet long by 24 inches wide, while the other tiles are only about 12 x 18 inches. A 4 foot sheet presents a *fac simile* of 36 tiles and an 8-foot sheet 72 tiles. The Spanish tile is exactly reproduced in size, the peculiar curves, the laps, &c., the imitation being so perfect that it would be difficult for any one to detect it without very close inspection of the roof. There are no patent locks or joints connected with it, but it is laid the same as the old-fashioned corrugated iron. The price is of course very much below that of the genuine tiling, being about one fourth as much. The Lloyd tiling is remarkably handsome in appearance and has already attracted a great deal of attention.

"The Metal Worker" Competition in Skylight Pattern Cutting.

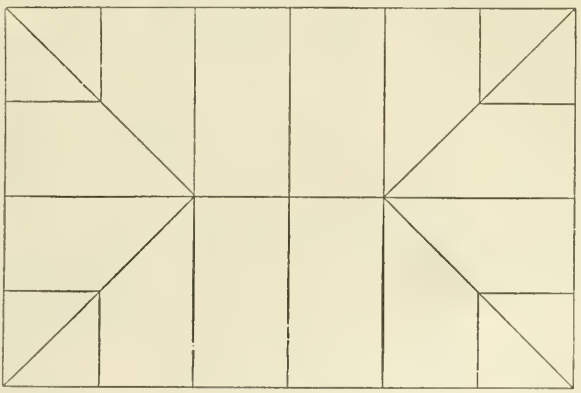
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

House Warming.—VI.

VACUUM OF SPACE.

Now, let us consider in conjunction the two facts that celestial space is a vacuum (and therefore devoid of any powers of conducting or absorbing heat from the passage of solar rays), and that the more remote planets receive less of the sun's heat than the nearer ones. If this latter proposition be true, it would seem to indicate that there is an absolute loss of heat, and not merely a change by transmission from one body to another, as in the cases previously referred to. And, if true on a large scale, there is good reason to believe that it would be so within the smaller limits, though whether to an appreciable extent is not clear. But, that from all sources there is a very considerable loss of heat in the passage from the radiant to the absorbent body is a fact clearly demonstrated by experiment.

Returning for a moment to the sun's rays—Box gives, as the result of observations, some valuable information, in the shape of definite quantities. By exposing a thermometer, with bulb blackened to facilitate absorption (see "polished silver" and "lampblack." Table XIII), to the full power of the sun's rays at noon, and to the effects of atmospheric temperature only, in shade, the following data were obtained: In January the average mean temperature in the sun was 47°. The average maximum in shade 43° As both readings were taken at the same time, the excess due to solar radiation is 47° − 43° = 4°, or 8½ per cent. In June, the results were 110° in the sun and 71° in the shade, the excess being 40°, or 36.36 per cent., as against 8½ per cent. in January.

Unlike conduction, the radiation of heat is irrespective of the thickness of the radiant body, the extent and character of the surface only being the governing factors. There is, however, similarity between conductivity and radiation, in that both are different in degree, in different materials.

EFFECT OF SURFACE.

Radiation is also greatly affected by the character of the surface, its color and comparative smoothness being very marked in their effects. Black and all dark colors and all rough surfaces radiate and consequently absorb heat with much greater rapidity than light colors and smooth polished surfaces. A familiar instance of this may be observed when the sun's rays fall upon ice or snow on the ground where the latter is rough and of very dark color—the snow will melt, even though the atmospheric temperature may be at zero, while that within a few inches of it upon a smooth light colored surface will show no signs of thawing. This, of course, is only illustrative of absorption, but there are examples of radiation quite as common, though the effects are not so easily observed. For instance, a black cast-iron tea kettle will cool the water it contains when removed from the fire far more quickly than will one having the same amount of external surface and made of bright tin. In Table XIII, from Box, we give the results of experiments by Péclet of the absorbing and radiating powers of ordinary substances.

Table XIII.—Absorption and Radiation.

Material.	Heat units per square foot per hour, for 1° difference in temperature.
Silvered copper—polished	0.02657
Copper—polished	0.03270
Tin—polished	0.04305
Zinc and brass—polished	0.04906
Tinned iron—polished	0.08585
Sheet iron—polished	0.09200
Sheet lead	0.13286
Sheet iron—black	0.56620
Glass	0.59480
Cast iron—new	0.64800
Chalk	0.67860
Cast and sheet iron—rusted	0.68680
Wood sawdust—fine	0.72150
Building stone, plaster, brick and wood	0.73580
Sand—fine	0.74000
Calico	0.74610
Woolen stuffs	0.75220
Silk stuffs, oil paint	0.75830
Paper	0.77060
Lampblack	0.81960
Water	1.08530
Oil	1.48000

We see by the above, not only the difference in radiating and absorbing power of different materials, but also that due to the color and character of surface, of the same material. For example, we find that in the case of polished copper, silvered and unsilvered, the difference is very marked, being 0.03270 heat unit for the latter and but 0.02657 for the former—a difference of 0.00613, or 23.55 per cent. greater by the plain copper than the silvered, due to color only.

To illustrate the difference from character of surface, apart from its color, we may consider the case of cast iron, new and clean, as compared with old and rusted—the latter being 0 6868 and the former 0.6480, making a difference of 0 0388, or 5.67 per cent. For the difference resulting from comparison of two materials having substantially the same color and character of surface, we may consider tin and silvered copper—both polished. For the former, the figure in table is 0.04906 and the latter, 0.02657, and the difference 0.02249, or 84.64 per cent. greater for tin, due to the nature of material only. Comparing the materials (solids) having the highest and the lowest power of radiation, we see by the table that they are lampblack and polished copper, silvered, the figures being 0.81960 and 0.02657 respectively. The difference, 0.79303, being nearly 300 per cent. greater for the lampblack. For sheet iron, black and polished, the difference is (0.56620 − 0.09200) = 0.47420, or over 515 per cent Comparing the power of radiation and absorption, as in above table, with the conductivity—Table XII—we find that copper, having the highest conducting power, is the lowest in the list of radiants, being 515 to 0.02657. Were it not for this fact, the use of sheet copper for stove cylinders, pipes and radiators would be undoubtedly good economy, notwithstanding its comparatively greater cost. As we shall see later, however, the radiant heat represents a large percentage of the total heat from all sources which can be realized from the use of any form of apparatus from which the heat is obtained by the exposure of its heated surfaces to the surrounding atmosphere.

LOSS BY CONVECTION.

Besides conductivity and radiation, there is but one other source from which the diffusion of heat may be obtained. This is technically termed the "contact of air." In its consideration there are numerous conditions which must be taken into account, and the subject is considerably more complex than either of the two last referred to. Clearly, the heating of a volume of air by contact with surfaces at a higher temperature must be accomplished through the indirect conduction of heat, successively, from the particles of air nearest to the heated surface to those most remote from it. As air is a very poor conductor of heat, the effect from contact with a heated surface is necessarily very slow as compared with the direct conduction by other bodies.

The loss of heat from absorption by the air in contact with a heated body is not affected by the kind of material of which the latter is composed, nor by the character of its surface. The temperature of surface alone is the governing factor as regards bodies of like form and position, though, as may be readily understood, the latter conditions, by having an influence on the circulation, must be taken into account. As we have seen by Table X, the weight of air varies considerably at different temperatures. At 62° 1 cubic foot will weigh 0.0761 pound, while at 209° it is but 0.0600 pound, and the difference shows that at the lower temperature to be 26.83 per cent. heavier than that at 202°.

It is therefore evident that, as the air directly in contact with the heated surface of a stove, for example, will not remain stationary, but that as rapidly as its temperature is increased and the weight correspondingly decreased, it will be displaced by the colder and consequently heavier air, which, in its turn, will become heated and displaced, thus establishing a continuous circulation, and diffusing the heat throughout the volume of air in the room. This being the case, it is readily seen that the form of body, and the position of its surface with reference to the vertical line, must affect the rapidity of circulation necessary to a maximum effect. Also, that the length of the surface, vertically, cannot be considered as only so many square feet of uniform effect, for the reason that as the air in contact with it continues to rise, it becomes warmer, and consequently the difference between its temperature and that of the surface is proportionately decreased.

Take, for illustration, the case of a vertical cylinder 2 feet in diameter by 20 feet high in which the number of units of heat lost per square foot per hour for each degree of difference between its temperature and that of the air in contact with it at bottom will be for the first foot in hight 0 6471, while for the whole 20 feet the average will be but 0.4487, or over 30 per cent. less.

As by a horizontal plane surface the circulation is the least rapid, it will suffer the smallest loss due to contact of air. Vertical planes, such as a wall, afford a much better surface for the free movement of currents, though the latter is confined to a direction parallel with the surface, and is therefore of the form of vertical surface by which there is the least loss. The horizontal cylinder comes next in order; and, lastly, the vertical cylinder.

The diameter of both horizontal and vertical cylinders is an important factor as regards the freedom of air circulation and consequent loss or diffusion of heat. In the former it is 0.7280 heat unit for 2 inches diameter and but 0.4381 for 36-inch. In the vertical, 0.7733 for 2 inch and 0.6377 for 36-inch. A globe, though of a form which is not likely to enter into calculations of the subject under consideration, may be mentioned as having, for small diameters, the greatest capacity for the diffusion of its heat by contact of air, and it likewise shows the greatest difference in effect in proportion to its diameter. Comparing it with the vertical cylinder of 2 inches diameter, we have as before 0.7733 for the latter, while for the globe it is 1 4110, and for 36 inches diameter 0.6377 and 0.4219 respectively.

In the following tables are given the results of calculations by Box from experimental data relating to the various forms and positions of surfaces above referred to. For practical application, the quantities given will require to be modified in some instances, and for this purpose supplementary tables by the same authority will be given in their proper place, together with the necessary illustrations of the methods by which their application to practical calculations may be made. In all of these tables, unless otherwise specified, the quantities given represent the loss in heat units per square foot per hour for each degree of difference in temper-

ature between the air and the heated body.

Table XIV.—Loss of Heat by Contact of Air from a Vertical Plane or Flat Surface.

Hight of plane in feet.	Average loss per square foot.	Hight of plane in feet.	Average loss per square foot.
1	0.5945	20	0.4133
2	0.5280	30	0.4037
3	0.4962	40	0.3980
4	0.4780	60	0.3924
5	0.4655	80	0.3871
10	0.4347	100	0.3843

As it may frequently become necessary to ascertain the loss for a given foot in the hight of surface, it may be readily calculated from the above quantities. Suppose it is desired to know the loss for the fourth foot in hight of a 10-foot wall or other plane surface. By the table we find the mean, or average loss per foot, up to that hight, to be 0.4780, and by the following progression we may calculate the individual loss for each foot up to that point. For the first foot the figure is 0.5945, which we subtract from that of the second foot multiplied by 2, which gives (0.5280 × 2) − 0 5945 = 0 4615, or the individual loss by second foot For the third foot we have (0 4962 × 3) − (0.5945 + 0.4615) = 0.4326, and for the fourth foot (4780 × 4) − (0.5945 + 0.4615 + 0 4326) = 0 4234. Table XV gives the loss for each foot in hight up to 10 feet:

Table XV.—Loss of Heat at Different Hights.

Foot from bottom.	Heat units.
First	0.5945
Second	0.4615
Third	0.4326
Fourth	0.4234
Fifth	0.4155
Sixth	0.4093
Seventh	0.4066
Eighth	0.4037
Ninth	0.4009
Tenth	0.3990

Mean = 4.3470 ÷ 10 = 0.4347, as per Table XIV.

To find the loss for horizontal cylinders and pipes of any diameter we add to the constant number 0.421, the quotient of constant 0.307 ÷ the radius or one-half the outside diameter of the pipe or cylinder. Thus for a 12 inch pipe $\left(0.307 \div \frac{12}{2}\right) + 0.421 = 0.4722$ heat unit per square foot per hour for each degree of difference in temperature. In Table XVI we have the loss for sizes from 2 inches diameter to 48 inches. Any sizes not given in table are easily calculated as above. In addition to the horizontal cylinder the table gives the figures for spheres of corresponding diameters, which are found by the rule (constant 1.0476 divided by radius) + constant 0.3634; and for a 12-inch globe we have $\left(1.0476 \div \frac{12}{2}\right) + 0.3634 = 0.5380$, as per table.

Table XVI.—Horizontal Cylinders and Spheres.

Diameter in inches.	Horizontal cylinder.	Sphere.
2	0.7280	1.4110
3	0.6256	1.0618
4	0.5715	0.8872
5	0.5440	0.7824
6	0.5230	0.7126
7	0.5087	0.6627
8	0.4978	0.6253
9	0.4892	0.5962
10	0.4824	0.5729
12	0.4722	0.5380
18	0.4551	0.4798
24	0.4496	0.4507
36	0.4381	0.4219
48	0.4338	0.4170

To use the figures in above table, find the outside area of pipe by multiplying the diameter in feet by 3.1416 and by the length in feet. Multiply this area by the number opposite the given diameter in table and by the number of degrees difference between the temperature of pipe and that of the air near to it. The result will be the total heat units lost per hour by the pipe from contact of air. If it is desired to know the loss per running foot divide this result by the length of pipe in feet, which will give the answer required.

For a sphere, the surface or area may be found by multiplying the diameter (in feet) by itself, and by 3.1416; then proceed as for the horizontal cylinder. The loss by vertical cylinders and pipes is found by a formula quite as simple in its operations as any of the preceding ones, although in appearance rather complicated. It may be expressed as follows: [Constant 0 726 + constant 0.2163 ÷ square root of radius of pipe in inches × constant 2 43 + (constant 5.49 divided by square root of hight in inches)] × constant 0 2044

For example, let us suppose a pipe 12 inches diameter by 20 feet high. We then have $\left[0.726 + \left(\frac{0.2163}{\sqrt{6}}\right) \times \left(2.43 + \frac{5.49}{\sqrt{240}}\right)\right] \times 0.2044$. The square root of 6 being 2 4995, and of 240 = 15.4919, the operation becomes simple addition, multiplication and division, and we have for answer 0.4634 heat unit. Table XVII gives the figures from 2 inches to 48 inches diameter, and the gaps between sizes may easily be calculated as above.

Table XVII.—Loss in Vertical Cylinders.

Hight of cylinder in feet.	Diameter of Cylinder in inches.						
	2	4	8	12	18	24	36
1	0.7773	0.7213	0.6846	0.6683	0.6350	0.6471	0.6377
3	0.6442	0.6088	0.5731	0.5591	0.5383	0.5416	0.5338
5	0.6046	0.5639	0.5353	0.5224	0.5121	0.5058	0.4985
10	0.5654	0.5273	0.5005	0.4886	0.4788	0.4730	0.4662
20	0.5363	0.5002	0.4747	0.4634	0.4542	0.4487	0.4422
30	0.5237	0.4885	0.4636	0.4526	0.4446	0.4382	0.4318
40	0.5164	0.4816	0.4571	0.4462	0.4374	0.4320	0.4255
50	0.5113	0.4769	0.4526	0.4418	0.4330	0.4278	0.4183

In order to ascertain the individual loss for any given foot in hight, we proceed by the same rule as given for vertical planes. Supposed it is desired to know the loss from a 2-inch steam pipe, at 3 feet from bottom end. Referring to Table XVII, we find that the mean loss for 2 feet hight is not given, and being necessary for our purpose, must be calculated. Then by the rule $\left(0.726 + \frac{0.2163}{\sqrt{2 \div 2}}\right) \times \left(2.43 + \frac{5.49}{\sqrt{24}}\right) \times 0.2044 = 0.6837$; and 0 6837 × 2 = 1.3674, from which, by subtracting the loss by first foot (by the table), 0 7733, we have 0.5941 as the individual loss by second foot, although the mean loss for the first 2 feet is (0.7733 + 0.5941) ÷ 2 = 0 6837, as previously calculated by the formula. For the third foot, the table gives the mean loss up to that hight as 0.6442. Then (0.6442 × 3) − (0.7733 + 0.5941) = 1.9326 − 1.3674 = 0.5652 as the loss for third foot.

It must be borne in mind that all of the foregoing tables and calculations are based on the supposition that the surfaces are exposed to a free circulation of the air surrounding them, as, for instance, a group of 2-inch pipes—say a steam radiator—will not give off their heat at the same rate as that just calculated for the single pipe, for it is clear that the natural circulation of air surrounding the individual pipes cannot be perfectly free. By means of a blast or other forcing medium the current may be made sufficiently rapid as to be the same in effect as the natural circulation by the isolated single pipe; and this is a plan very commonly adopted in the improved methods of steam heating, to which reference will be made in its proper place.

Hot-Air Furnaces.

In a recent volume of the proceedings of the Engineers' Club of Philadelphia was the following note by George T. Gwilliam:

The difference in the cost of steam or hot-water apparatus, when compared with hot-air furnaces, will make the latter the most popular method of heating dwellings for some time to come. The heater in common use is of the portable type, made up of a cast iron fire box, with a system of wrought or sheet iron drums and tubes the whole covered with a sheet-iron jacket, from the top of which the heat pipes diverge. To supply moisture to the heated air a cast iron water box is located at some point of the heater to suit the fancy or convenience of the workman; the box will hold from 1 to 3 gallons, and seldom contains water, usually mud and rust; the heat pipes are seldom tight and rarely covered. The cracks and crevices around the cellar windows and the foundations of the house supply the heater with fresh air; it collects, in its passage across the cellar, coal dust, ashes and the different odors commonly found in cellars; the gases from the leaky heater joints are added, then it is delivered throughout the house at varying temperatures, from 60° in very cold weather to 140° when the weather moderates.

In theory the question of heating and ventilating should go hand-in-hand; the practice is, however, to heat only. While it is next to impossible to get a heater that is perfectly tight, a good one can be selected—one with a minimum number of joints—and it should be large enough to heat the volume of air required without forcing. The fire box of a heater should not be allowed to get red hot. The pipes conducting the heat should be run direct, avoiding abrupt turns and horizontal runs. The jacket of the heater and the heat pipes should be covered with some non-conductor. The water pan, properly placed, should be connected with a tank having a ball cock, so the water supply will be constant.

All rooms should have some means of ventilation, and when no provision has been made to that end, good results can often be obtained by simply adjusting the window sash.

Since the introduction of laws regulating house drainage and plumbing in this city, the character of the work has changed greatly for the better; and if similar laws were passed regulating heating systems, much sickness arising from breathing impure air and gases from defective heaters would be avoided.

A foot warmer, says the Paris correspondent of an English exchange, depending for its action on the slacking of quicklime, has been invented by M. Loison de Viviers, who divides the case into two compartments, one containing lime and the other water. The flow of water on to the lime is regulated by a valve, adjusted from the outside, so that it is possible to regulate the degree of heat by the quantity of water admitted to the lime. It is said that the temperature may attain the boiling point of water, and be maintained thereat for a considerable period, varying with the size of the foot-warmer.

Tin ore in very promising quantities is said to exist in the Margui district of Lower Burmah. Prospecting and mining licenses are said to have been recently granted to a syndicate of British and Chinese capitalists.

PLUMBING AND GAS FITTING.

Common Errors in Plumbing Practice.

It has been suggested to us that having published in connection with the "Plumbing of a City House" in the issue of February 25, 1893, all that is called for in the line of advanced sanitary pumbing, it would serve a useful purpose to bring pointedly before those of the plumbing trade who need such reminders the common blunders in plumbing practice so frequently made, either through carelessness or ignorance, or both. In accordance with the suggestion, we present a few of those things which the plumber and helper would do well to avoid, but which it must be acknowledged are not unfrequently found to exist even in jobs of plumbing that have passed from the hands of journeymen who not unfrequently believe that they have nothing to learn.

It is well to begin at the foundation of the house-plumbing system by raising the first note of warning to the plumber against

IMPROPER GRADING OF HOUSE, SEWER AND DRAIN

at the outset. It is by no means uncommon to see these pipe lines laid from the sewer in the street to almost the full depth of cellar—that is, back to the rear wall—before it is discovered that the grade is too steep, when the work has to be done over again. If, for instance, the pipe had to be laid in a trench under cellar floor, and a certain head-room had to be secured at back of cellar, it could not be accomplished satisfactorily unless the plumber took the precantion to provide for it at the outset instead of afterward having to alter the grade.

SETTING THE TRAP AT FRONT WALL AT AN ANGLE.

This should be avoided, as the trap, if set at an incline, will empty itself and defeat the object of placing it on the main drain.

BREAKING JOINTS IN HORIZONTAL LINES.

This is a trade term which means inserting the spigot end of one length of pipe into the hub of another at an angle so as to effect a slight deviation in the line. This leaves the calking space in the hub unequal, besides taking away from the smoothness of the interior bore of pipe. This should be avoided, and where any deviation is called for it should be made with "bends" or other fittings, so that the joint in the hub can be equally calked all around.

USING QUARTER BENDS ON HORIZONTAL LINES

is not good practice and helps to check the flowing sewage. If a deviation is necessary it is better to use two-eighth bends than one-quarter bend, the sharp angle of the latter being thus avoided.

DOUBLE TRAPPING HORIZONTAL LINES.

There should not be more than one trap on a horizontal line, as "air-bind" is likely to result, thereby checking the flow of sewage. Branch horizontal lines needing trapping should be trapped before connection with main line.

DRAINING FRONT AREA INTO HOUSE SEWER OUTSIDE MAIN TRAP

should be carefully avoided. Even if the drain is trapped it is not always certain that the trap is sealed in dry weather, and there is consequent danger that sewer air will come through and enter the house by the doors and windows. If the area drain cannot be brought into the cellar and connected with house drain at inlet side of main house drain trap, it should be drained into the fresh-air inlet. It would then be safe.

DISCHARGING VERTICAL SOIL AND WASTE PIPES INTO HOUSE DRAIN THROUGH T OPENINGS

is bad practice. The tendency is that sewage discharged in this manner is liable to accumulate in the drain pipe and eventually close the opening. The vertical line should be connected with the house drain by, and discharged through, Y branches and eighth bends.

TRAPPING VERTICAL SOIL AND WASTE PIPES AT BASE

is not permitted in good work. The only trap allowed on a vertical line of pipe is where the rain leader is inside the building, when as a precaution it is trapped at the base as a protection for adjacent houses with windows opening above the roof.

USING T CONNECTIONS ON VERTICAL SOIL AND WASTE LINES.

This should be avoided. A closet with a half S trap connected with a T opening discharges the sewage, not down the soil pipe, but in a straight line against the opposite side of the pipe instead of downward as with the use of a Y branch. Unnecessary fouling of the pipes is the consequence.

DISCHARGING BATH AND BASIN WASTES INTO WATER-CLOSET TRAPS.

This is a matter of too frequent occurrence, but should be carefully avoided, also neglecting to separately trap baths and vent the trap in usual manner.

CONNECTING BATH AND BASIN OVERFLOW PIPES BELOW THE TRAP

is an error very frequently encountered and a very dangerous one. These overflow pipes should always connect with waste pipes on the inlet side of traps.

SETTING WATER CLOSETS WITH INSUFFICIENT SIZED FLUSH PIPE

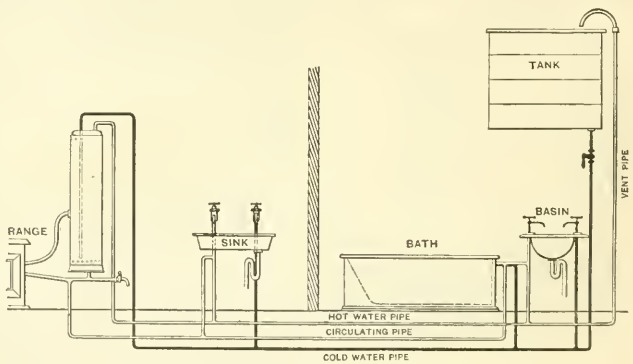
is something to be guarded against. The value of a flush is greatly enhanced by the immediate discharge through a pipe at least $1\frac{1}{4}$ inches in diameter.

DRAINING SAFES UNDER CLOSETS INTO THE CISTERNS OF CLOSETS ON LOWER FLOORS.

This is a reprehensible habit. A water closet apartment has at all times an abundance of aid to foul-smelling without the water in flushing cistern being fouled before being used.

OTHER IRREGULARITIES.

Viz.: Trapping regulator and safe wastes into soil pipe, connecting the overflow of house tank on upper floor with water-closet cistern, placing traps at long distances from fixtures, connecting sediment pipe of boiler on outlet side of trap of kitchen sink, making bowed or trapped vents to traps, &c., all of which mistakes are certain to lead to bad results and to redound to the injury of the plumber who does the work. In this, as in other cases, there is abundant room for the application of the ounce of prevention.



Range Boiler Emptied through Relief Pipe.

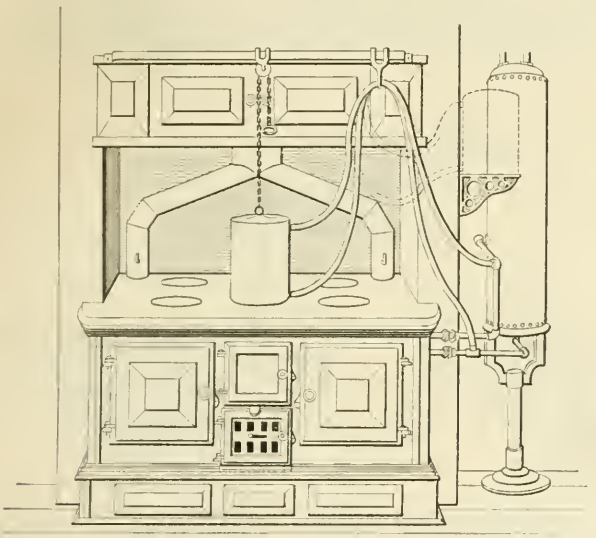
Range Boiler Emptied through Relief Pipe.

From C. Q. A., *Ohio.*—I inclose drawing of work that has given me considerable trouble, and I wish to have some assistance from the trade. As soon as the boiler fills up with water it will syphon back into the supply tank through the vent pipe. The work is all on the second floor, with pipes running under the floor and as nearly level as they can be put. The water is all supplied with the tank pressure, the bottom of the tank being on a level with the boiler. The capacity of the tank is 27 barrels, and it makes no difference whether the tank is filled or only two-thirds full, the action will be the same. You will see that the circulation pipe is branched into the hot-water pipe, both at the sink and wash basin; also into the bottom pipe leading from the boiler to the stove. The pipe conducting the water from the top of the boiler to a point within 12 inches of the bottom has a hole in it near the top. The stove water back is at the side, as shown. We had no trouble in heating the water. The piping is all of $\frac{5}{8}$-inch lead pipe. The water syphons when it is hot.

Movable Water Top.

We describe below an attachment for a range boiler devised by E. C. Tainter, Madison, Wis., and which he calls Tainter's Latent Heat Retort for kitchen ranges. The engraving, which is made from a photograph of the apparatus, shows its principal features. It is designed to utilize more fully the heat from the range and serve as a sort of supplementary water back. The apparatus illustrated is only an experimental one, and was made movable by flexible steam hose. We understand, however, that this particular attachment was used with much satisfaction, and gave such good results that the hose was replaced with metallic fixtures and joints, permitting the kettle to be moved. According to the illustration, the kettle can be placed either on the range or on a shelf, as indicated by the dotted lines. Describing this apparatus, Mr. Tainter writes as follows :

"The can shown in the photograph is a hot-water retort or movable water top, supplementary to the water back. In this case of preliminary work it was made movable by flexible steam hose, one for cold water and the other for hot water. The two acted the part of hinges, and by them the retort can be placed on any pot hole and set aside when not required. All parts of the apparatus are in sight. The capacity of the boiler has been doubled by the use of the retort. The picture shows a lifting chain and shelf for the retort, where it may be placed out of the way. The chain and shelf, however, were never made, as they were not needed. The flexible hose is shown too long. It is only necessary to have it long enough to straighten out and bend readily. The cold-water connection is branched from the cold-water pipe of an ordinary kitchen boiler to the retort, from which a hot-water pipe is connected in the same way to the hot pipe of the ordinary water back at any point near the boiler."



Movable Water Top.

Waste of Water.

From J. B., *Brooklyn, N. Y.*—There is a great quantity of literature written on the waste of water during the winter and the hot months of summer. What I wish to say relates to the waste in winter. I live on the second floor of a private house where the water is heated by a range on the first floor. When I want hot water I have to waste all the water which comes before the hot does. The cold water is so close to it, furthermore, that when I want cold water the water is warm and it has to waste before the cold water comes. I think it would be a good thing to have a clause in the plumbing regulations of the city to have a return pipe so that the hot water could be procured the instant it is turned on, also that the cold-water pipes should be 15 inches or so from any part of the hot-water pipes. I would like to hear from those who are better qualified to write on the subject.

TRAPS AND VENTS.

THE MIDDLESEX COUNTY COUNCIL in England have, as reported by a London plumbing exchange, established a class on plumbers' work in connection with the Museum of Sanitary Appliances at Highgate, London. A registered foreman plumber is appointed as instructor, and the board have ruled that the teaching shall be alternately technical and practical. The class is open to those actually engaged in the plumbing trade, either as apprentices or otherwise. A nominal fee of 60 cents for the course is imposed, and this will be returned to those students who make 75 per cent. of the possible number of attendances. Similar plumbing classes appear to be commencing all over the United Kingdom, and promise to be a prominent feature of British trade education.

A LARGELY ATTENDED MEETING, convened by the British Institute of Public Health, was held at the Mansion House, London, on February 18, in order to discuss the training and examination of sanitary inspectors and plumbers. The conference, which included medical men and sanitary authorities from all parts of the United Kingdom, unanimously passed a resolution to the effect : "That this congress of delegate representatives of the sanitary authorities of Great Britain and Ireland is desirous of recording its opinion that the systematic training, examination and registration of plumbers is essential to the protection of public health, and that a statement embodying this opinion should be presented as a memorial to Parliament, coupled with an expression of the further opinion of the congress that the Plumbers' Registration bill should be passed into law at the earliest opportunity in the interests of public health." Copies of the resolution were transmitted to the various State departments and chairmen of sanitary authorities throughout the Kingdom, under the signature of the Lord Mayor of London.

A GERMAN GAS JOURNAL tells the following curious story : A plumber had been doing some soldering of a gas connection and had as usual turned on the gas and applied a flame to see if any gas kindled. He observed no flame and concluded that the job was secure, and went away. But although he had not seen it, there was a flame ; gas was escaping through an extremely small orifice in the solder, and this minute escape had kindled and was burning with a minute blue flame. This minute and practically non-luminous flame continued burning for six weeks, gently widening the aperture, and after six weeks the flame was long enough to begin to char wood in its vicinity. The odor of charring was detected and the cause of the mischief removed in time.

C. H. ROSE of the Old Dominion Mfg. Company has just returned from a week's inspection of their works at Shendun, Va. He refers to business as good and prospects all that could be desired. They have 96 employees at work there and $20,000 worth of orders booked ahead. They are receiving at their New York warehouse, 242 Water Street, a carload of manufactured goods every week. They are producing a good grade of water-closet seats, tanks, bathtub rims, valves and fittings belonging to this line. Mr. Rose has sent down a foreman for the machine department and also a foreman for the bench (or carpenters') department within the past two weeks, and will start a foreman next week to assume charge of the metal department.

NICOLAS BARRY, Muscatine, Iowa, has been granted a patent on a plumbers' trap, consisting of the trap having a lateral T, adapted to extend through a wall or partition and thereby support the trap ; also a screw and cap to close the end of the T and with a central opening with an adjustable inlet pipe and suitable packing rings. The object is to provide an efficient water seal that can be placed behind the wall or wainscoting and cleansed, and with which pipe connection can be quickly made.

ALLEN P. CREQUE, New York, has been granted a patent on a new form of washbowl, one object being to dispense with the independent faucets. The bowl is provided with an auxiliary chamber communicating with the bottom portion and containing hot-water and cold-water inlet. Another feature of the invention consists in dispensing with the usual cap or plug for closing the outlet, the purpose being served by a tube inserted in the outlet pipe of the bowl.

THE TORONTO STEEL CLAD BATH & METAL COMPANY, LIMITED, Toronto, Ontario, are distributing very pretty circulars printed in gold and colored inks giving "the reasons why the Steel Clad is the best." A variety of reasons are referred to, and the article itself is shown in gilt and colored illustration.

JAMES B. CLOW & SON, manufacturers and dealers in plumbers' supplies, Lake and Franklin streets, Chicago, are making extensive alterations and improvements in their private offices on the third floor. The offices are being enlarged and the walls and ceilings handsomely decorated. The kitchen and dining room, which have long been an institution of this house, are to be removed from the third to the sixth floor, thus giving more office room. The dining room is to be finished in Georgia pine.

THE SMITH & ANTHONY STOVE COMPANY, New York and Boston, proprietors and manufacturers of the Sanitas plumbing specialties, J. A. Cunningham, Western manager, 319 Lake street, Chicago, are to furnish Sanitas traps and closets for the Marshall Field Building, Monadnock

extension, Old Colony Building and Art Institute building, Chicago. They also furnish 100 Sanitas traps for the Teutonic Building.

JAMES B. CLOW & SON, Lake and Franklin streets, Chicago, announce to the trade that they have this year established shipping yards on the north, south and west sides of that city, so that they can make prompt shipment over any railroad entering Chicago. In addition to their regular stock of cast and wrought iron pipe carried in these yards, they have added a complete stock of vitrified sewer pipe, having accepted the agency of the largest manufacturer of Akron sewer pipe in this country.

THE WELLS & NEWTON COMPANY, D. M. Quay, Western manager, 1108–1109 Monadnock Block, Chicago, are to do the plumbing in the Chicago Athletic and Art Institute buildings. Also in the following buildings at the World's Fair: New York, Victoria, White Star, Puck, Walter A. Baker, French and Kentucky. Also, Moorish Palace, Venetian Murano and Zoological Arena. The above firm also do the plumbing in the Union Trust building, St. Louis, which is the first 15-story structure built in the city.

Trouble With a Range Boiler.

A correspondent in Indianapolis, Ind., sends the following letter and drawing relating to a bit of work a tinner and stove man may be called on to do. He writes:

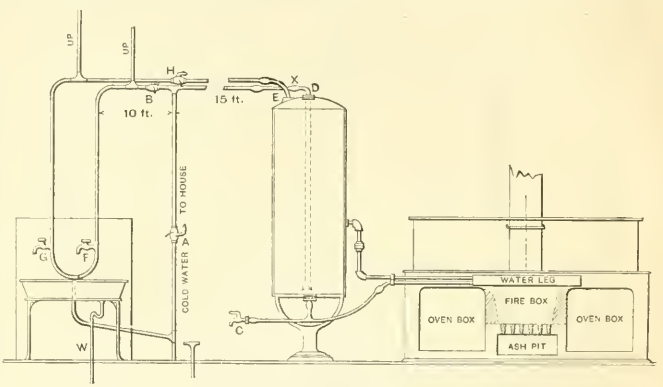
Our firm, whose principal business is in hot-air furnaces, steam and hot-water heaters, also handle an extensive line of family and hotel ranges. The usual custom when a range is sold is to send out a man from the shop to set it up. By this it is meant his work is to properly locate the range in a kitchen in relation to the smoke flue of chimney, and also to set the water back or leg in the range so that the pipes can readily be got at by the plumber who has to make the connections with the water boiler. The plumbing in our city must be done by a regular licensed firm or mechanic in that trade, and when so done, as a matter of course, they are responsible for their part of the work.

In the instance of which I write a range had been put up in the kitchen of a hotel several years ago in a locality where there has been considerable trouble with the water supply by reason of the connecting pipes filling up with hard scale, the pipes from the range in question proving no exception. Whenever this trouble occurred some plumber had been sent for, who usually remedied it by cleaning out the water leg and the connecting pipes. During the recent very cold spell, when almost every plumber was too busy to attend to any new orders, word was sent to our office that the pipes were stopped up again. In addition to this the parties mentioned that the boiler rumbled, and, in fact, made so much noise that their kitchen help were afraid of an explosion. As no plumber could be secured at the time our foreman had to send over a tinner.

To let out the water from the boiler he shut off the cocks at A and B in the cold-water supply pipe and loosened the connections at D. (See accompanying diagram.) After the water had been drawn from boiler at cock C for a time the connection at D was taken off entirely, permitting a steady flow from the boiler through the cock C. While the water was being emptied bucketful after bucketful the man had to wait and could not, of course, do any work on the pipes from the range. But, in the meantime, by judicious questioning, he obtained all the points necessary on how the plumbers did the same work on former occasions. About this time it occurred to him that the boiler ought to be empty, but judge of his surprise to find that it was nearly full, being steadily fed from the hot-water outlet E, at the top of boiler. Searching for the cause of this, he found that the cold-water supply pipe had a branch pipe to the cold-water faucet F, and from there the pipe continued upward to supply the balance of the house with cold water. I may add that the hot-water faucet G had been opened from the beginning to draw off the hot water from the building, but by this time instead of hot water cold water was running from it, proving conclusively that there was no plug or stop in the bend from F to G.

As it was not advisable to shut off the cold-water supply to the house, our man finally found a shut-off cock in the hot-water pipe at H. This he turned off, when, of course, the flow to the boiler ceased, and shortly the boiler was emptied through cock C. He then uncoupled and took off the entire connection between the boiler and water leg, also taking out the water leg.

Here he met with another surprise, the entire connections, including the water leg, proving to be entirely free from scale. And so the only thing he could do was to put back the water leg in position and couple up the connections as he had found them. He then informed the landlady that the fault lay with the plumbing work, and in fact that his labor was thrown away in so far as stopping the noise in the boiler was concerned. After filling the boiler again he, therefore, left.



Trouble with a Range Boiler.

Next morning early he reported to the foreman what he had found and done. The foreman thereupon determined to find out what really was the cause of the trouble. Taking along the necessary tools, and also the same tinner to help him, they arrived at the hotel just after breakfast was over. This gave him a chance to work, as no fire would be needed for several hours in the range. I may also mention that a plumber and helper who had been found were taken along. About this time a considerable quantity of hot water was being drawn off at G, but after the faucet G was closed for several minutes the rumbling, snapping and noise in the boiler commenced again and lasted for quite a while, when it finally stopped. Meanwhile there was still a big red-hot fire in the range. The foregoing operations of drawing hot water and shutting it off were repeated several times, always followed by the same noise in the boiler.

Weighing these facts in his mind, it occurred to the foreman that perhaps the boiler did not receive a sufficient supply of cold water to compensate for an equal amount of hot water drawn off. Having emptied the boiler, therefore, he uncoupled the cold-water supply pipe from the top of boiler. His idea was to see if there was any obstruction in the supply pipe, so, taking a piece of No. 16 gauge wire, he shoved it up into the bend D. When it had entered as far as the first wipe joint, shown at X, it stopped, but by poking and shoving for a few moments the wire finally entered somewhat further. This experiment proved to him that there must be some obstruction inside the pipe. He then took a saw and cut the pipe through about a foot away from the bend D, and found that the plumber who had made the joint had almost closed up the passage, leaving but an irregular hole from $\frac{3}{16}$ to $\frac{1}{4}$ inch in size. It was learned that several days previous a plumber had done some repairing, and put in a new piece of pipe from that very same joint to the next joint, shown in the drawing. A new piece of pipe being put in at D to where the pipe was cut—but this time properly—the pipe was again connected to the boiler. A division was also made in the bend between F and G. This work done, the boiler was again filled and a brisk fire started in the range. After the water in the boiler became heated again the same experiment of drawing hot water for a time and then shutting it off was repeated, but no snapping or rumbling noise followed.

The elevator capacity of the head of the lakes is at present 21,200,000 bushels. The only two cities in the country which have elevator capacity in excess of this amount are Chicago and New York, that of the former being 30,075,000 bushels and the latter 27,275,000 bushels. The elevators are now crowded to their utmost. To care for the surplus lines and to open new territory, elevators are now being built in Superior for an additional capacity of over 6,000,000 bushels and in Duluth of over 1,000,000 bushels, which will place Superior Duluth second in the United States in point of elevator capacity.

The shortage of cars is still a subject of grievous complaint at various Western points, but is felt with special severity at Kansas City. The superintendent of car service in that section says the trouble is caused very largely by sending cars long distances without transferring, to New Orleans and Baltimore, for example, so that they are longer returning. It requires five times the number of cars to do the business, now that they are permitted to go through.

A foreign corporation doing business in Massachusetts is not liable for taxes upon its personal property there, under chapter 11, section 20, of the Public Statutes. The full bench of the Supreme Court so decided on the 9th inst. in the suits of the Boston Investment Company and others against the city of Boston.

Philadelphia complains that she is rapidly losing her grain trade owing to alleged discriminations in favor of Baltimore.

Tricks and Manners of Syphons.

BY L. ALLEN.

To understand some of the anomalies in the action of syphon pipes for conveyance of water, a refereuce to the principles on which their action is based is necessary. All the more is this needed because the text-books that treat of syphons usually omit to speak of more than one principle, whereas there are several.

A good example of the usual mode of treating this subject is the following, from "Ganot's Physics," a treatise of high reputation and widely used in schools. The

"To explain this flow of water from the syphon let us suppose it filled and the short leg immersed in the liquid. The pressure then acting on C (surface of liquid) and tending to raise the liquid in the tube, is the atmospheric pressure minus the hight of the column of liquid D C. In like manner the pressure on the end of the tube B is the weight of the atmosphere less the pressure of the column of liquid A B. But as this latter column is longer than C D, the force acting at B is less than the force acting at C, and consequently a flow takes place proportional to the difference between these two forces. The flow will therefore be more rapid in proportion as the difference of level between the aperture B and the surface of the liquid in C is greater." This is the whole story. The writer has looked in many treatises for a better exposition, without success. To show how inadequate it is, a modification of Fig. 1 is herewith given and, without violating any definition, principle or direction laid down by Ganot, an inoperative syphon may be constructed.

In Fig. 2 every detail is shown substantially as set forth by Ganot, except that a trumpet-shaped tube is used, having its smaller end immersed in the liquid to be discharged. The discharge from the larger end being much larger than the supply entering the smaller end, the longer leg of the syphon will soon empty itself after it is filled and placed, as set forth by Ganot, and the flow will then cease immediately.

Does this not indicate that there are other principles involved in syphon action than mere difference of pressure at the two ends of the tube? Does it not point clearly to the fact that the rate of inflow to that of outflow must be always equal, or the siphon will be inoperative?

It may be said that inflow and outflow must be equal so long as the pipe is of uniform internal diameter, or at least if the two mouths are of equal discharge areas.

While this is theoretically true, it does not always hold in practice. The writer was called once to doctor a syphon pipe that supplied a penstock from a stream over an intervening rise of ground, roughly estimated as 16 feet above the source of supply. From the source the rise was very gradual for half a mile, where it reached the crest at a distance of about 60 yards from the penstock. No one had yet been able to explain the reason why this recently-laid pipe had, after apparently working well for about a week, gradually diminished its flow for a day or two, and, finally, suddenly ceased to flow altogether. Several attempts had been made to start it again by attaching a suction pump to the discharge end, and though a little water could thus be got, the flow again suddenly ceased. The pipe had been put in by a local dealer in pumps, stoves, tin roofing, &c., who, chancing to be a personal friend, solicited advice about the difficulty. After hearing his story, it was concluded that there was an obstruction in the shorter leg of the syphon, and reasoning that if any body, as an eel or a frog, had caused the stoppage, the cessa-

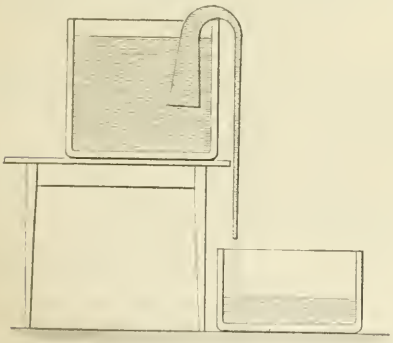

Fig. 3.—Operative Syphon.

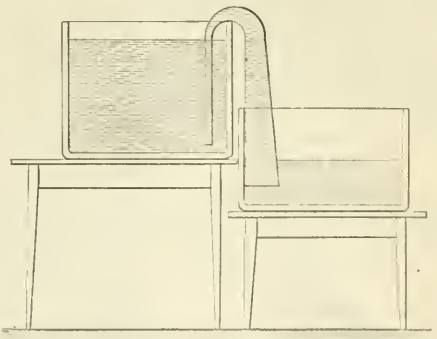

Fig. 4.—Another Style of Operative Syphon.

TRICKS AND MANNERS OF SYPHONS.

whole discussion given in this work to syphons of constant flow occupies less than a page, including two cuts used as illustrations. A short paragraph on intermittent syphons is added, and the subject is then dismissed.

First, a definition of a syphon is given as "a bent tube, open at both ends and with unequal legs." The word "leg," as applied to syphons, is left undefined, but the context must inevitably lead the reader to infer that the two parts of the pipe joined at the bend are what is meant by legs.

How a syphon is used for emptying liquid from a vessel is then described, that is to say, how to fill it and place in the vessel. By means of a cut substantially like that herewith given in Fig. 1, the adjustment of the syphon is shown, then there are 11 lines of explanation which I quote *verbatim*:

tion of flow would have been sudden and without the gradual approach described, the case was diagnosed as one of gradual accumulation of sediment in the shorter leg, reaching an extent at which the inflow was insufficient to prevent the longer leg from emptying itself. As confirmatory of this theory, considerable muddy deposit was found in the penstock. By using a force pump and forcing considerable water through the pipe from the discharge end back into the stream, thus washing out the short leg of the syphon, and extending the longer leg so as to make it always discharge below the surface of water in the penstock, and so that the longer leg could not empty itself at any reduced velocity of flow, it was found that a gradually diminishing flow through several weeks would be obtained. The stream at all times after summer rains was very muddy, and a strainer at the inflow end was therefore also recommended, but a periodical washing out of the syphon continued to be necessary.

In Figs. 3 and 4 are shown two different ways of making operative a trumpet-shaped tube, which, as arranged in Fig. 2, will not operate unless it be a capillary tube, and, as enforcing the principle that a syphon to be operative must be arranged so that inflow and outflow shall be equal, a careful study of these diagrams is recommended.

As with muddy water the clogging of a syphon by silt will be less when the velocity of inflow is small than when the velocity is great, it is always wise to use at the inflow end several lengths of pipe considerably larger than the remainder of the run, whenever the source of supply is subject to becoming soily from any cause.

To prevent any misunderstanding, it is added that without respect to the actual length of pipe extending either way from the highest point in the pipe, the longer leg is always on the discharge side relatively to that point; or, to put it in another way, the longer leg of a syphon is the one that has the greater vertical hight from its mouth, as measured from its mouth to the level of the highest point in the pipe.

Hot Pipes.

A digest, compiled by H. A Phillips, of the municipal laws relating to hot pipes in buildings, in force in some of the principal cities of the United States, appears in a recent issue of the *American Architect and Building News* They are as follows:

Boston.—1. Hot-air pipes shall be at least 1 inch from wood work.

(This may be modified by inapector in first-class buildings.)

2. Any metal pipe conveying heated air or steam shall be kept 1 inch from any wood work, unless pipe is protected by soapstone or earthen tube or ring, or metal casing.

Baltimore.—1. Metal flue for hot air may be of one thickness of metal, if built into stone or brick wall.

2. Otherwise it must be double, the two pipes separated by 1 inch air space.

3. No wood work shall be placed against any flue or metal pipe used for conveying hot air.

Chicago.—1. Hot-air conductors placed within 10 inches of wood work shall be made double, one within the other, with at least ½ inch air space between the two.

2. All hot-air flues and appendages shall be made of IC or IX bright tin.

3. Steam pipes shall be kept at least 2 inches from wood work, unless protected by soapstone, earthen ring or tube, or rest on iron supports.

Cincinnati.—No pipes conveying heated air or steam shall be placed nearer than 6 inches to any unprotected combustible material. All subject to approval of inapector.

Cleveland.—1. Hot-air conductors placed within 10 inches of wood work shall be made double, one within the other, with at least ½ inch air space between the two.

2. No pipes conveying heated air or steam shall be placed nearer than 6 inches to any unprotected combustible material.

Denver.—Metal flue for hot air may be of one thickness of metal, if built into stone or brick wall; otherwise it shall be made double or wrapped in incombustible material.

Detroit.—No metal pipe for conveying hot air shall be placed nearer than 3 inches to any wood work. Such pipes over 15 feet long shall be safely stayed by wire or metal rods.

District of Columbia—1. Hot-air pipes shall be at least 1 inch from wood work.

2. Pipes passing through stud or wooden partitions shall be guarded by double collar of metal, "giving at least 2 inches air space, having holes for ventilation, or other device equally secure, to be approved by inspector."

3. Metal pipe or otherwise double, and the space filled with 1 inch non-combustible, non conducting material, or a single pipe may be surrounded by 1 inch of plaster of paris or other non conducting material between pipe and timber.

Kansas City.—1. Any metal pipe conveying heated air or steam shall be kept 1 inch from any wood work, unless pipe is protected by soapstone or earthen tube or ring, or metal casing, or otherwise protected to satisfaction of superintendent.

2. No wooden flue or air duct for heating or ventilation shall be placed in any such building.

Memphis.—1. All stone or brick hot-air flues and shafts shall be lined with tin pipes.

2. No wooden casing, furring or lath shall be placed against or cover any smoke flue or metal pipe used to convey hot air or steam.

3. No metal flues or pipes to convey heated air shall be allowed unless inclosed with 4 inches thickness of hard, incombustible material, except horizontal pipes in stud partitions, which shall be built in the following manner: The pipes shall be double, one inside the other, and ½ inch apart, and with 3 inches space between pipe and stud on each side; the inside faces of said stud well lined with tin plate, and the outside face with iron lath or slate. Where hot-air pipe passes through partition, shall be at least 8 feet from furnace.

4. Horizontal hot-air pipes shall be kept 6 inches below floor beams or ceiling. If floor beams or ceiling are plastered or protected by metal shield, then distance shall not be less than 3 inches.

5. Where hot-air pipes pass through wooden or stud partition, they shall be guarded by double collar of metal with 2-inch air space and holes for ventilation, or by 4 inches of brick work.

6. No hot air flues or pipes shall be allowed between any combustible floor or ceiling.

7. Steam pipe shall not be placed less than 2 inches from wood work unless wood is protected by metal shield, and then distance shall not be less than 1 inch.

8. Steam pipes passing through floors and ceilings or lath and plaster partitions shall be protected by metal tube 2 inches larger in diameter than pipe.

9. Wooden boxes or casings inclosing steam pipes and all covers to recesses shall be lined with iron or tin plate.

Milwaukee. — 1. Hot air conductors placed within 10 inches of wood work shall be made double, one within the other, with at least ½ inch air space between them.

2. All hot-air flues and appendages shall be made of IC or IX bright tin.

Nashville.—1. Sheet-iron flue running through floor or roof shall have a sheet-iron or terra cotta guard at least 2 inches larger than flue.

2. Steam pipes shall be kept at least 2 inches from wood work.

3. All steam and hot-air flues and pipes must be suspended by iron brackets.

Newark.—1. Hot-air pipes shall be set at least 2 inches from wood work and the wood work protected with tin.

2. Such pipes placed in lath and plaster partitions must be covered with iron, tin or other fire proof material.

New York.—(Same regulations as noted under heading of "Memphis.")

No hot-air flue or pipe allowed between combustible floor or ceiling.

Omaha.—1. Steam pipe shall not be placed less than 2 inches from wood work unless wood is protected by metal shield; and then distance shall not be less than 1 inch.

2. Steam pipes passing through floors and ceilings, or lath and plaster partitions, shall be protected by metal tube 2 inches larger in diameter than pipe.

3. Wooden boxes or casings inclosing steam pipes and all covers to recesses shall be lined with iron or tin plate.

4. Stud partitions in which hot-air pipes are placed to be at least 5 inches wide, and the space between studs at least 14 inches.

5. Hot-air pipes shall not be placed between floor joists unless same are doubled and the joists 14 inches apart.

6. Bright tin shall be used in construction of all hot-air flues and appendages.

Providence.—1. Hot-air pipes shall be at least 1 inch from wood work, unless protected by soapstone or earthen ring, or metal casing permitting circulation of air around pipe.

2. Steam pipes must be kept at least 1 inch from wood work, or supported by incombustible tubes or rest on iron supports.

St. Louis.—1. Hot-air pipes shall be at least 1 inch from woodwork, unless protected by soapstone or earthen ring or metal casing permitting circulation of air around pipe.

2. Steam or hot-water pipes carried through wooden partition or between joists, or in other close proximity to wood work, shall be inclosed in clay pipe or covered with felting or other non-conducting material.

San Francisco.—1. Metal flue for hot air may be of one thickness of metal, if built into stone or brick wall, otherwise double, one pipe within the other ½ inch apart, and space filled with fire-proof material.

2. No wood work shall be placed against any flue or metal pipe used for conveying hot air.

3. Steam pipes shall be placed at least 3 inches from wood work, or protected by ring of soapstone or earthenware.

Wilmington.—Metal pipes to carry hot air shall be double, one inside the other, ½ inch apart; or, if single, have a thickness of 2 inches of plaster of paris between pipe and wood work adjoining same.

Henry B. Clark, Chicago, Ill., has been granted a patent on a hot water heater, being an apparatus for heating water for domestic and other purposes.

The following list shows the total mileage of new railway track constructed annually in the United States during the last ten years; the figures covering main line single track only, and not including the mileage of second, third, fourth, and other tracks laid along the main line, nor of sidings, spurs, private tracks, etc: 1883, 6743 miles; 1884, 3924; 1885, 2984; 1886, 8037; 1887, 12,983; 1888, 7028; 1889, 5696; 1890, 5671; 1891, 4471; 1892, 4062 miles. The total mileage in existence in this country at the end of 1892 is computed at 174,663 miles, of which 104,000 have been laid down during the last 20 years.

THE RETAIL STORE.

The Stove and Tin Business. III.

BY VETERAN.

After considering the subject of competition of the dry goods and furniture dealers, it is well to ask if the regular trade do not make for themselves a much worse and certainly needless competition. The work done outside of the tin shop, roofing, conductor pipes, smoke jacks, cleaning furnaces and heaters and ranges and, in fact, almost all of the repair work done, and a large part of what is done inside, is both very hard and dirty work, and calls for experience and ability to do it well, and should pay good profits. It does pay good profits, and customers seldom dispute a bill or ask for time, and yet I think I am correct in saying that there are no uniform rates for this work, and the result is that many timid men charge less than they should for fear of being too high in prices.

I had occasion lately to put on a 6-inch smoke jack with a plain flange at bottom and the ordinary pitched circular top 10 feet high. I knew it was worth $6 put up made of galvanized iron No. 26, and yet, as it happened to be a little out of my district for work, I called on a dealer near where it was to go and asked what he would make and put up the pipe for for me and he said $8. I went away satisfied that I could not be out of the way, but when I sent in my bill I was told by the owner that he had one put on of the same dimensions on another piece of property for $4, and I had to accept that price. The price should have been agreed upon before the work was done, but it was ordered by the real estate agent of the owner, who had paid some bills to me before without any disagreements, and so it was not done. This is a fair sample case of the way ordinary job work is carried on.

There is a remedy for this bad situation, but it is like taking bitter medicine to adopt it. It lies in having familiar intercourse between dealers in the same locality, and perhaps an association of retail metal workers outside of any regular trade union. I would not for a moment advise any combination with forfeit or absolute agreement not to vary a hair from a certain price for a certain job. The most that can be done is for each man to say on his honor that he will charge such a given price for stove-pipe elbows, galvanized pipe conductor, and all work that can be rated, and then a price per hour for tinner and one for helper. Make cleaning furnaces, heaters, labor putting in grates and brick, and all work of that character, time work.

The guarantee that will do the most good and bind the agreement is to find that it is kept substantially by all. Once get the confidence of each other and it will come certainly if there is fair play, and in time all will see the benefit and ease of the plan. It removes the unpleasant feeling that now exists whenever one is asked for prices, not knowing who may be called on or what other figures will be made by a competitor. Even if work is lost by cutting it is better to have your figures substantiated at the outset, and care must be had to guard against men who run back and forth with stories of what some one else will do work for to get low prices. Better to lose a job once in a while and prove the statement and then apply some remedy for it. The most difficult part of my plan is to get cranky men who are never ready for improvement to come down from their jackass and make friends and confidants of their competitors. Self-interest ought to compel what good manners will not always accomplish.

How to Avoid the Accumulation of Dead Stock.

SECOND ARTICLE.

By H. C. WISEMAN.

A common answer would be—get rid of it before it becomes "dead"—which is pretty hard to do as a regular thing.

You have seen the back-number merchant who insists he never had any dead stock, and you see every day the wide-awake merchant, who knows such goods in a larger or smaller degree must be a part of the business. Like any other business disease, it can be gotten rid of, if taken in time, without great loss. Styles change, something else supersedes. The demand falls off, and this is the time to take hold of such goods, if the business eye will only see it.

KEEPING AFTER IT.

There are merchants who don't want to see it, others will—after stock inventory. The prudent, watchful merchant is on the lookout for it at all times. When looked after but once a year, it is easy to find an accumulation, and one with a value—even as a scrap pile, or old Iron. But it must be gathered together, turned over, assorted, laid out, and made the most of. As the caption of the above is how to avoid, rather than how to get rid of, such accumulations, allow me to suggest again, that any avoidance at all comes only with eternal vigilance, and that future avoiding comes only with previous riddance, and necessarily the two are very closely allied.

KNOWLEDGE OF STOCK.

We have always made it a point to keep a separate clean-up or bargain counter, taking everything that tends to slow sale, or to depreciation in value, brightening up, remarking, and putting it here, mixing in other goods that will help it off. If one remarking will not do it we give it another.

The largest help in avoiding all accumulation is to know your stock thoroughly, from front door to back. Keep pushing it forward, never hiding it, knowing probable customers who will use such and such lines, and never losing sight of goods or customers.

Broken dozens, single pieces, odd jobs and left overs must be put out, classified and pushed. Clerks must understand when a Sash Lock, Door Bolt or Escutcheon is called for, not to open full packages, or regular goods, if there is the slightest chance of working off the other. Nine times out of ten they will go at a price, and before you are aware of it that odd stock is gone.

In making stock memoranda, to fill up or purchase for, we make it a rule to watch for goods that are not moving. As a result of such work we are able to pride ourselves on the smallness of these accumulations.

ATTRACTING ATTENTION.

On the clean-up tables or counters it is always possible to make a fairly good display. In addition a clever man with a marking brush will have saved all odd pieces of pasteboard coming in, and will use them for signs to go with the goods. Such as:

ODDS AND ENDS.
See prices.

BROKEN STOCK.
Half price.

JOB LOT.
Was 50¢, now 25¢.

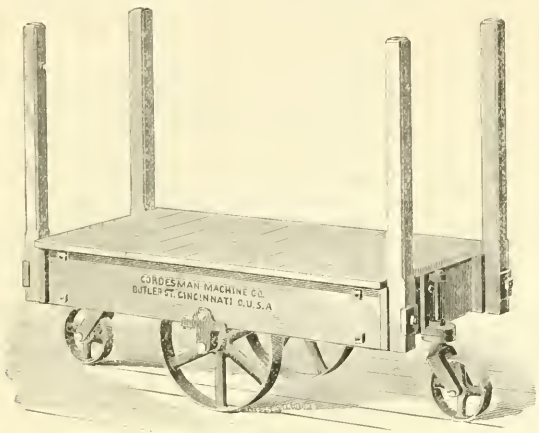
With ordinary care, and the same attention that is given to other detail, it can be kept at a minimum, and need never be a bugbear.

A PARTICULAR CASE.

As an example of what can be done in getting rid of such goods, we some time ago found a house with nearly 1500 cheap Hatchets, boys' and men's Axes (all ordinary stock for 10 years). We bought them all at half price, and for two weeks filled both large show windows, a counter and racks at the door, in attractive display, with a sign which possibly had two meanings, but which sold the goods, *i. e.*, "They won't last always," and others much like it. We were able to close out the last one in a little over three weeks. So it is with a general line, if goods are watched, the work put on them, and ordinary business intelligence used, the stock need never quite reach the absolutely "dead" point.

Factory Truck.

Cordesman Machine Company, 43–47 Butler street, Cincinnati, Ohio, are introducing a truck for factory use, as shown herewith. It has a hard wood frame of 2 x 7 inch material, the end rails being gained in the side pieces and each fastened by two bolts that are plowed in and pass through from end to end. The standards are also of hard wood 2 x 2½ inches in size and 36 inches long. These are clamped rigidly to the frame by a device, and can be detached by simply loosening a nut. The swiveled wheels are provided

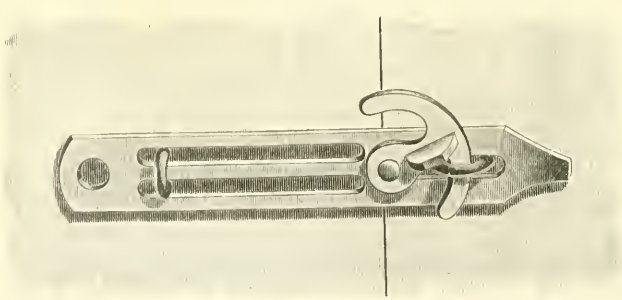


Factory Truck.

with flanges to prevent the rods from bending when striking obstructions. The center wheels are 16 inches in diameter with a 2½-inch face. They revolve on a steel axle 1¼ inches in diameter, which also revolves in boxes, resulting in a light-running truck. The point is made that all the iron parts are fitted together carefully and machined, not cored. The trucks are made in two sizes of platform, 24 x 48 inches and 30 x 60 inches. It is remarked that the use of such a truck systematizes the work in a factory as it is moved from one machine to another, keeping the floor neat and clean, and avoids the confusion incident to shops where material is placed and scattered over the floors.

Pugh's Adjustable Hook, Hasp and Staple.

A. F. Shapleigh Hardware Company, St. Louis, Mo., are introducing the above article, as shown herewith. The staple may be driven through the hole in the end, as in the ordinary hasp, or in the



Pugh's Adjustable Hook, Hasp and Staple.

slot, as shown in the cut. Using the hasp with the staple in the slot allows its adjustment to doors or gates that shrink or sag, thus giving the hasp 2 or more inches of play; while the ordinary style of hasp has less than ¼ inch play, necessitating the removal of the staple to properly adjust it to the door or gate. The hasps and hooks are right or left hand, and are made of solid steel, in regular sizes.

Henn Can Opener.

A. S. Henn & Co., New Haven, Conn., Cranston & Jennings, 80 Wabash avenue, Chicago, agents, are introducing the can opener shown herewith. It is described as all steel, made light and strong with the best of care and with a fine cutting edge. The grooved pulley working on the edge of the can allows it to be used on the top or side of can and either right or left hand. It is neat in appearance and is referred to as a fine clean cutter and sure grip. It is made with imitation ebony handle, nickel plated; also with enameled handle, polished.

Henn Can Opener.

Two Cases.

BY A. F. G.

Merchants are induced, sometimes against their better judgment, to buy a sample of something outside of the line regularly handled by them, but still a legitimate Hardware article. In many cases such investments prove unprofitable, although merchants in adjoining towns are successfully selling the same goods, and find for them an increasing demand. The

SAMPLE ARRIVES,

is examined, and commented upon by the proprietor and clerks, and then perhaps laid on a cook stove or refrigerator. In the press of business, showing and explaining and selling such goods that are called for, the sample is forgotten. Some one in showing the stove or refrigerator to customers lays the sample on the floor; next morning when the sprinkling and sweeping is done, the sample is

SHOVED INTO A CORNER OR INTO A BIN,

or behind the counter. It is later covered with other goods, and not discovered until taking inventory, when its shop-worn condition unfits it for sale. The proprietor wonders, if he does not say it right out, why clerks are so careless. He is disgusted with trying new things, and has lost confidence in the salesman who induced him to buy the sample, and with traveling men in general. Unfortunately for the merchant, this was the last trip for the traveling man who sold him the article, or on his next trip he would probably have looked around and said, So you have sold that sample already. How did your customer like it? Thus the article might have been rescued from its ignominious end.

ANOTHER CASE.

Now the question arises, How did the other merchant in the adjoining town create a demand for the same kind of goods? We will suppose the article in question to be a Lifting Weight, an athletic apparatus for home use. When it was unpacked it was nicely dusted off, the accompanying description was read and thoroughly digested, and the machine given a prominent place for actual use. It was not put so high that no one could work it, nor where things would be piled up in front of it, but where any customer could try it and see how it worked.

SIGNS.

Then the merchant had the sign maker (who owed him) paint neat signs on cardboard, one for each of the show windows, stating that such an apparatus was on exhibition, and inviting customers to come in and try it, free of charge. Then he had another card made to hang in the store over the machine, giving its name and inviting people to try it.

TALKED IT UP.

When the merchant made his deposit at the bank next day, he told the clerks what a fine thing he had at the store for them, and they promised to come in that evening and see it. He put a flea in the ear of the young man in the cigar store, and gave a similar hint to his lawyer, and spoke to others whom he thought needed and would appreciate something at home upon which to exercise. It is unnecessary to follow in detail this merchant's subsequent trade in athletic goods, or to state how from this one machine his stock of this class of profitable goods increased until his store was considered headquarters for athletic goods for that region of country.

Tin and Sheet Iron Job Workers' Unions, Nos. 61, 62 and 63, will soon establish a school for apprentices, at which instruction will be given in cutting, shaping and designing, besides other points that naturally come in the line of the trade.

Starrett's Gauges.

The gauges shown in the accompanying cuts are being put on the market by L. S. Starrett, Athol, Mass.

The gauge, Fig. 1, is referred to as having the following improved features, viz.: A joint at the base which allows the spindle jointed to this may be set and rigidly held in any position from vertical to horizontal, and the scriber placed in position to be used below its base for depth gauge, or (with bent end down) a scribing gauge. The point is made that it weighs 11 ounces and is 5 inches high, and, folding the spindle (which is 4 inches long) horizontally over the base, it may be packed in 1⅜ inches x 1¼ inches x 4 inches space in the tool chest.

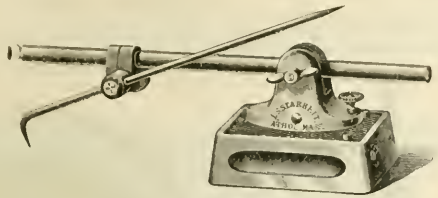


Fig. 1.—Starrett's Universal Surface Gauge.

The stair gauge, Fig. 3, is to be used in connection with any carpenter's steel square, and can be adjusted to any pitch or angle desired. It is designed for cutting in rafters, braces, stairs, &c.

spindle and scriber to be moved back and forth and placed in any position from upright to horizontal to reach over, back of and under work, while by inclining the spindle over the work its scope for long reach is increased.

The fine adjustment is obtained by the knurled screw in the rocking bracket at the base acting against a stiff spring under

Fig. 2.—Tool-Makers' Universal Gauge.

the opposite end, while the joint above with the spindle may be set and rigidly held in any position desired. Two pins through the base, frictionally held, it is stated, may be pushed down by slight pressure to form a bearing to work from the edge of, or in the slots of the planer bed for lining up work, while the weight of the gauge against the bed with a little pressure is sufficient to push them back. Grooves around these pins, against which a pointed spring plunger presses, insure

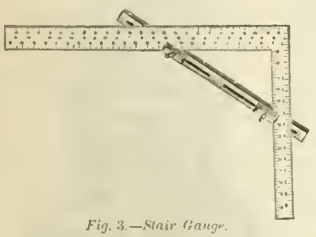

Fig. 3.—Stair Gauge.

their being held in place either up or down. Concaved depressions milled in the sides of the base are designed to make it convenient for thumb and finger to grasp.

This gauge is furnished with an improved sleeve to rigidly hold the scriber.

The gauge shown in Fig. 2 is adapted for light work and is made on the principle of the one illustrated in Fig. 1.

The base is steel, case-hardened, with depressions milled in the sides for the thumb and finger to grasp. The top side of it is slotted, and the rocking bracket is pivoted in the same. There is a stiff spring under one end of the bracket and a knurled adjusting screw in the other; the

Acme Dinner Pail.

Acme Stamping Company, East Stroudsburg, Pa., have put on the market a dinner pail, as shown in the accompanying illustrations. The feature of the pail is Strayer's bail ear and cover fastener, which is plainly shown in Fig. 1. In it is a spring brass ear and catch in one piece, designed to engage both ends of the cover or coffee can, so as to hold the same securely and not allowing it to be displaced by upsetting or falling, or from any accident which dinner pails are subject to. The makers remark that the fastener saves workmen's dinners, which might otherwise be spilled out and made unfit for eating. The pail is well made of heavy material, with a wired top edge, and with the cup inside the rim on the top of the coffee can. This rim is 3¼ inches in diameter, giving an opportunity of introducing the hand to thoroughly clean the coffee can. The can has the seam in the center, both the upper and lower parts of the can being stamped, and the projecting seam forms the rim over which the catches hold. As shown in Fig. 2, the stamped tray rests

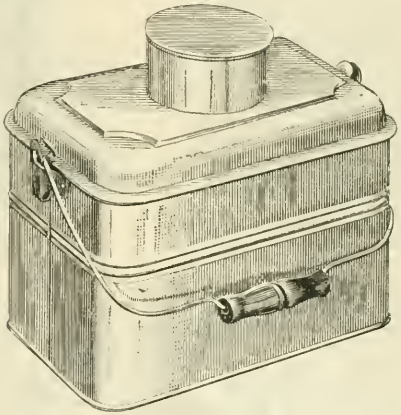

Fig. 1.—Acme Dinner Pail.

on four lugs soldered in the corners of the can just below the swage. The pails are made in three sizes, each pail separately wrapped in heavy paper and packed in

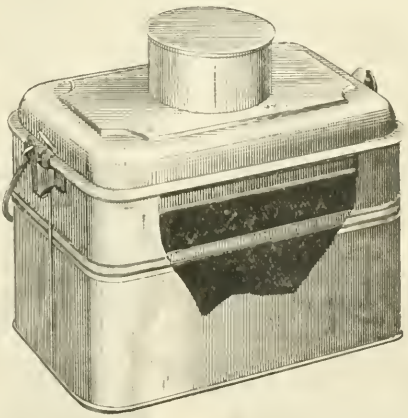

Fig. 2.—Showing Interior of Pail.

It is made in the shape of a steel angle ⅞ x ⅞, ⅛ inch thick, ground straight, nickel plated, and is referred to as a most valuable addition to a carpenter's kit of tools.

cases made especially for the purpose. The manufacturers remark that the bail ear and cover fastener is not expensive, as the pails are put on the market at a price as reasonable as other pails made similar to these.

The Perfection Mold.

Ideal Mfg. Company, New Haven, Conn., have put on the market an adjustable mold for grooved bullets only, as shown in Fig. 1. In Fig. 2 a partial idea is given of the work which can be done with the mold. It is explained that the adjustment in the mold can be varied, not only one groove at a time, but any fractional part thereof, varying the length and weight 5

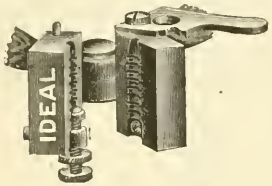

Fig. 1.—The Perfection Mold.

or 10 grains at a time, anywhere between the lowest and highest limit, thus securing any weight desired. The points of bullets of any length being the same, one adjustable chamber or seating screw answers for all. The point is made that with this mold the owner can determine for himself just what is in his rifle at all ranges, with every variety of powder charge and weight of bullets, all at the expense of one mold. The bullets in Fig. 2 are shown with a hollow base and the molds can be made as ordered, but the experience of the manufacturers lead them to prefer the flat base, as it does not gather and hold grease when lubricating. With hollow bsse bullets the grease must be thoroughly wiped off before seating upon the powder. The manufacturers state that the Perfection mold will not be made for all calibers, but only for a few of the popular sizes; neither will they be made for patched bullets, as their cylindrical mold is designed for patched bullets; also that the Perfection molds will invariably be made to cast bullets slightly above size so as to allow for shrinkage of all mixtures, and the bullets may require

Fig. 2.—Bullets Cast in Perfection Mold.

sizing, which will make them all uniform and perfectly round, &c.

These molds are made for the following calibers:

25 caliber, diameter 0.257 ; weight 56, 67, 77, 86 and 96 grains.
32 caliber, diameter 0.311, 0.379, 0.323; weight 75, 100, 125, 150, 175, 200, 225 grains.
32 caliber, diameter 0.319 (32-40 M) ; weight 80, 120, 155 grains (special short range).
38 caliber, diameter 0.375 ; weight 135, 170, 205, 245, 285 and 325 grains
45 caliber, diameter 0.457 ; weight 305, 365, 405, 465 grains No. 5, 45 Government Tool O. K.

Aluminum Cooking Utensils.

Illinois Pure Aluminum Company, Lemont, Ill., are manufacturing these goods in saucepans, frypans, washbowls, tea and table spoons. The samples of stamped saucepans which we have seen show the goods well and neatly made, with aluminum handles riveted on, and an entire absence of solder. These are made in 1, 2 and 4 quart sizes, and weigh as follows;

1-quart saucepan.....3¾ ounces
2-quart saucepan.....8 ounces
4-quart saucepan.....17 ounces

The manufacturers claim for these goods freedom from poison, lightness, great heat conductivity, heat-retaining properties, cleanliness, impossibility of rust and absence of all solder. They state that under no circumstance can poison be extracted from aluminum, and that these utensils possess all the virtue of porcelain-lined utensils in cooking delicate food, such as milk or fruits. The goods, we are advised, are meeting with ready sale.

Screw-Base Fence Post.

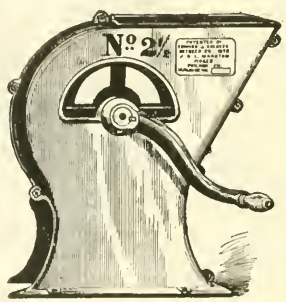
Capital City Fence Company, Indianapolis, Ind., are offering a screw-base post, as illustrated herewith. The post is described

Screw-Base Fence Post.

as having the base cast from gray iron with two spiral flanges extending along opposite sides of the base, at a right angle from the center and at a uniform angle of 45° on the plane of the post. This construction enables the posts to be screwed into the ground instead of being driven or set in holes, and the manufacturers claim that after the post is in position the flanges give a direct and effectual resistance to the heaving action of frost, to the pulling of the wires over unequal ground surfaces and all other usual strains. It is stated that the post can be used successfully in any kind of soil and that it will remain substantially as placed.

Creasey Ice Breaker.

Jos. S. Lovering Wharton, Germantown Junction, Philadelphia, Pa., is introducing a new style and design of the Creasey ice breaker, as herewith shown. The picks or teeth used on the drum are of forged steel, while the general construction is referred to as tending toward compactness and strength. The machine is arranged for bolting to a wooden stand, which forms a receiver below for the broken ice. The breaker is recommended by the makers for use in hotels, restaurants, and for caterers and ice cream manufacturers.



Creasey Ice Breaker.

Ideal Roller Base for Oil Stove

The Huette-Barler Mfg. Company, 111 and 113 Lake street, Chicago, have devised a roller base for their Ideal oil

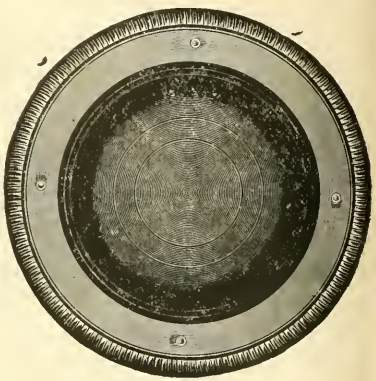


Fig. 1.—Ideal Roller Base.

heater, which they are now manufacturing for the trade. Fig. 1 is an illustration of this base. It is circular in form, made wholly of metal, has a nickel rim and curved fluted edge, a hard-baked japanned

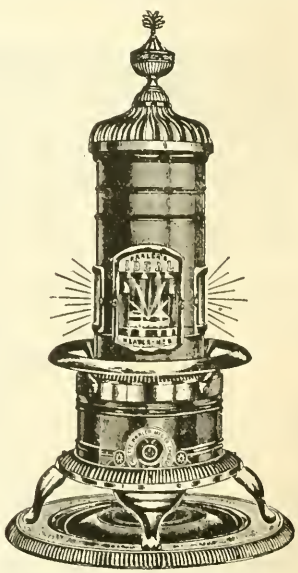

Fig 2.—Roller Base in Use.

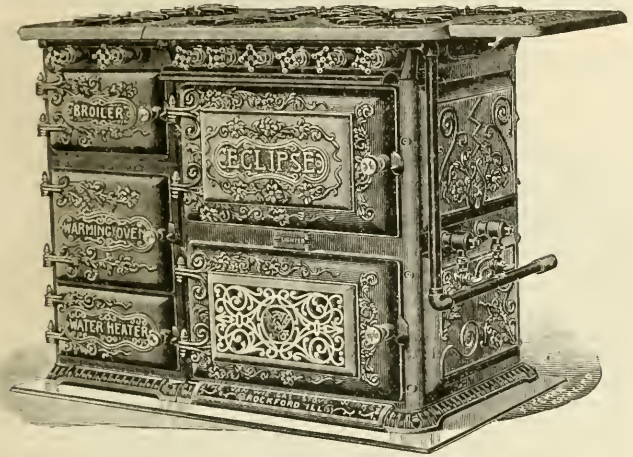
center, and is mounted on lignumvitæ wood wheel casters, on which the heater can be easily moved about. Fig. 2 is an illustration of the roller base in use. The legs of the stove are set immediately over projections on the base, securing a firm hold and covering the projections from view. The rim is deeply curved, so as to hide the caster from view also.

The Eclipse Gas Range.

In the accompanying illustration we present a general view of the Eclipse gas range, which has been brought out by the Van Wie Gas Stove Works of Rockford, Ill. The stove here shown is provided with six burners in the top plate, a large oven, broiler, warming closet and water heater, and is presented to the trade as first-class in every respect. The manufacturers state that the beauty of this range is in the size of its ovens. These are 19 inches wide, 17 inches deep and 12 inches high, while the hight of the range itself is only 32 inches, thus making it very convenient for cooking purposes. It is claimed to be lower than any range on the market. The construction is such that the square top range with four burners in the cooking surface can have the broiler, warming oven and water heater with the two burners in the top, added at any time without disconnecting the stove from the gas supply. The ornamentation, as may be seen from an inspection of the accompanying cut, is neat and effective, and the company confidently expect for the Eclipse a hearty welcome and an extensive demand at the hands of the trade.



Eclipse Gas Range.

Protection to Merchants.

A retail hardware merchant of Iowa referring to this subject expresses his views as follows:

While I may be, and am, among the little fish as a merchant, yet I am able to think, and my thoughts on this subject are summed up in a few words. If the manufacturers wish to be fairly dealt with and wish the patronage of jobbers, and through the jobbers the retail trade, the manufacturers should see to it that their goods are placed in the hands of the regular jobbers and not in the hands of retail jobbers. For instance, I will mention one line of goods especially which are being sent out to our should-be customers at prices about as low as I can buy the same goods from my jobber. The goods I refer to are a line of Firearms, manufactured by one of the largest concerns in the country. A customer comes into my store, asks the price of one of their Rifles or Repeating Shot Guns. I name him a close price for cash. Well, he answers, I can get those goods of Messrs. ——— for much less money, &c. My advice would be that manufacturers protect the jobbers, and that jobbers protect the retailers.

He remarks in closing that Firearms were selected as an example, as a case of this kind had come up during the day, but that the entire Hardware business is becoming demoralized on account of jobbers quoting low prices to consumers.

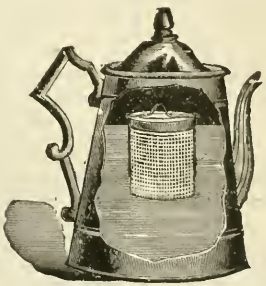
A New Ice Chopper.

A. M. Ross & Co., Ilion, N. Y., are putting the ice chopper illustrated herewith upon the market. It is made from one piece of steel, so formed as to make the handle socket identical with the chisel blade, the handle being self-tightening by use. The two pieces, blade and handle, complete the chopper, except for those who like more weight, a cast-iron socket head in ball form is provided. This is attached to the end of the handle, thus making a heavier chopper.

A New Ice Chopper.

West's Percolator.

T. G. Ellsworth, 85 Chambers and 67 Reade streets, New York, is offering the percolator, as illustrated herewith. It consists of a perforated metal basket, with a hollow air-tight cover, which causes the percolator to float. Lugs fastened on the edge of the cover turn under stationary ears soldered to the basket, holding the cover in place. A ring is soldered on the cover by which the percolator is removed from the hot liquid. The sheets of which the basket is made are tinned after being perforated, thus covering the raw edges and avoiding rust and discoloration of the coffee. The basket has a swage a little more than half way up to indicate how much coffee should be put in, the space above being left for the water to percolate through. It is explained that in use the float holds the percolator at the surface, where the agitation of boiling water is the greatest, and that the action of the water forces out all the strength of the coffee. The point is made that the percolator saves the trouble and cost of eggs for clarifying, keeps the grounds from sticking on sides of the pot, clogging the spout, coming into the cup, and a thousand and one annoyances there are in putting the coffee loose into the pot. The percolator is made in four sizes, to make from 12 to 36 cups of coffee.



West's Percolator.

MEMORANDA.

James K. McGuire of Syracuse, N. Y., has become a member of the wholesale hardware firm of Bradford, Kennedy's Sons & McGuire. Mr. McGuire had been confidential man in the firm for many years, and is deserving of the promotion that has come to him.

Frank Ricker, 69 Warren street, New York, is making a specialty of One Minute and The Boss Coffee and Tea Pots and Urns. These are designed to be used with pulverized coffee or tea, and it is claimed effect a large saving in the quantity used while producing superior results.

Lumber combines are forming North and South to secure control of the largest possible amount of growing timber. At Toronto a syndicate is in course of formation which will include some of the largest operators in Michigan and Canada, and options have been secured on several thousand square miles. The name of Governor Alger of Michigan is prominently mentioned.

A new treaty between France and Canada is designed to promote the interchange of a variety of products, but the list affected is comparatively small. The arrangement follows the same lines as that between France and the United States, the reductions of duty being limited to a certain number of articles, the trade in which is of about the same amount on each side.

STOVE TRADE NOTES.

Meeting of the Defense Association.

A meeting of the Stove Founders' National Defense Association was called for Thursday, the 16th inst., at Chicago, for the purpose of considering an advance of 15 per cent. in the wages of molders. The matter was brought to the attention of the Defense Association the latter part of February by the Molders' Union, under an agreement entered into some time since between the two bodies, which stipulates that where an increase of wages is requested thirty days' notice shall be given, the advance in wages asked for to take effect on April 1. According to the call, the Association met on Thursday at the Auditorium Hotel, Chicago, the session being held with closed doors. The decision reached will hardly be made public until it is submitted for approval to a general meeting of the stove manufacturers, which was to be held in the same hotel on Friday, the 17th inst. The molders have not made the demand for an advance, but have put it as a business proposition, claiming that stoves are now sold too cheap and that they should be advanced to a more profitable rate so as to enable manufacturers to pay better wages to their workmen.

(*By Telegraph.*)

We received the following dispatch from Chicago Friday, March 17:

The meeting of the Defense Association yesterday was very fully attended, members being present from all sections of the country. A thorough discussion of the request of the molders for higher wages resulted in the opinion that the condition of the trade does not warrant an advance. Final decision was, however, reserved until the matter should be considered by the general meeting of the manufacturers to-day.

WE ARE INDEBTED to the Quick Meal Stove Company of St. Louis, Mo., for a copy of a circular which was issued by them for distribution among the Western trade some eight years ago, when the care and operation of vapor stoves was not so well known as at the present time. The circular tells what gasoline is, and explains why the Quick Meal gasoline stove is not dangerous. It also tells the work that can be done on a Quick-Meal stove, setting forth its advantages over a coal stove, and gives the expenses of operation. It is illustrated with numerous engravings of gasoline stoves, accompanied by ample descriptive letterpress. This circular is now reissued for distribution by the Eastern agents of the company, the S. M. Howes Company, Boston, Mass.; and the fact that trade literature used eight years ago in the West is considered proper for the Eastern trade at the present, illustrates very forcibly the relation between the two sections of the country in the matter of using gasoline for heating and working purposes.

Claims for Castings Broken in Shipment.

(*Concluded.*)

FIRE CRACKS.

The question of fire cracks, for which claims on the stove manufacturer are so often made by the dealer, is one that can hardly be brought under one rule like that of the responsibility for breakage of castings in shipment. In the absence of any special agreement by the wholesaler to deliver goods to destination in perfect condition, a general rule or custom in the stove trade obtains, and the dealer must look to the transportation company for redress when breakage in transit occurs. In this case, although small country dealers, not well informed, often consider it an injustice of the wholesale merchant, and decline to bear the loss when breakage occurs, the rule is not, however, open to any reasonable complaint against its fairness to both buyer and seller, because the shipper's goods must first stand an inspection at the freight depot or shipping wharf before the agent of the carrying company will give a receipt in good order. After obtaining such receipt it must be plain to the dullest understanding that the shipper has made delivery of perfect goods and his responsibility is at an end.

In the case of fire cracks, however, the manufacturer cannot be always free from responsibility, although the times when he is responsible are few as compared to the number of times demands are made upon him for free castings to replace some cracked by fire.

It is not exaggerating to say that nine times out of ten, when fire cracks occur, the stove wholesaler is asked to replace the casting free or the new piece is ordered in such a way, with indignation or reflecting upon the quality of the plate, it being plainly intimated that it ought to be free and is expected free, no matter to what the crack or break may have been due.

The stove business is one which the dealer embarking in it too often seems disinclined to pay to learn. He is apt to blame the castings for any and every accident that befalls a stove from natural causes.

If a man in the furniture business puts an article too near the fire and the wood becomes warped, or if water from a leaky pipe falls on a bedstead, thereby starting the varnish and the glue, he does not berate the manufacturer and demand that the damage be made good to him: but if a stove dealer neglects to loosen the bolts of a range when putting it up and the top cracks when the plate expands from the heat, he insists that the stove is no good and demands a new top free of expense, and is quite apt to charge the maker for the time occupied in putting it on.

SOME CAUSES OF CRACKS.

He will drive 10 miles in winter with the mercury at zero with a stove whose plates are as brittle as glass from the extreme cold, and after putting it up leave an ignorant housemaid to start a booming fire in it with the resultant cannonading of the top and oven plates, and then turn around and curse the stove to the manufacturer of it.

He will write to the maker for a set of covers which ought to be free, as the ones they are to replace cracked in a very short time after he sold the range—the range itself too being the same style of which he has sold dozens without any similar complaint, when he knows all the time that his customer ordering the covers has a slovenly housekeeper who slams the vessels on the stove and slops the cold water in all directions, which is sure to split the red-hot covers. Or he will tell you that his customer thinks he ought to get a new set of fire fixtures free, because those in the range cracked all to pieces, all other possible causes to such a result being unworthy of consideration, and it is taken for granted it must be the fault of the stove.

But there are times when he is not to blame and when the cracking of plates by fire is in consequence of faulty pattern making and the plates bear too snugly against each other to stand the expansion of the iron when the stove is fired up. But this only happens with new stoves when first introduced, and there must be very few manufacturers who would not promptly recognize their responsibility in such cases and send the new plates free, and even be liberal in reimbursing the dealer for the expense or loss incurred. In fact, the manufacturer is specially desirous of knowing of any weakness developing in a new construction, and nobody can be more deeply interested in making the defect good and having the dealer satisfied at any reasonable cost.

The Littlefield Stove Company.

Among the concerns engaged in the stove industry in Albany, N. Y., is one to which peculiar interest attaches by reason of the prominent part which has been played by its proprietor in the production of coal and wood burning constructions. It is probable that few men have done more to develop and extend the stove industry of the United States than D. G. Littlefield of the Littlefield Stove Company. He and his work are the subject of a column article in a recent issue of an Albany periodical, entitled "Every Saturday." It gives a brief history of the life of Mr. Littlefield and his connections with the stove trade, illustrated by an excellent portrait. We make the following extracts from the article, which may prove of interest to many of our readers:

He was born in Wells, Maine, in 1817, and is the eighth in direct descent from Edmund Littlefield, who with his large family, settled in Wells in 1638 and was called the founder or father of Wells. At an early age he was apprenticed to the tinsmith trade, served his time, and made and saved enough money to start in business on his own account by the time he was 21 years old. He was quite successful for ten or 15 years, and during his spare moments invented the base-burning stove. Up to this time stoves were close, ugly affairs, put up by their owners in the fall at the last moment and taken down as early as possible in the spring. His invention revolutionized the whole industry and made chestnut coal the most expensive grade,

where previously it was a drug on the market. The Morning Glory parlor stove, the first of the base burners, was a handsome affair for those days, and for years it was almost impossible to satisfy the demand.

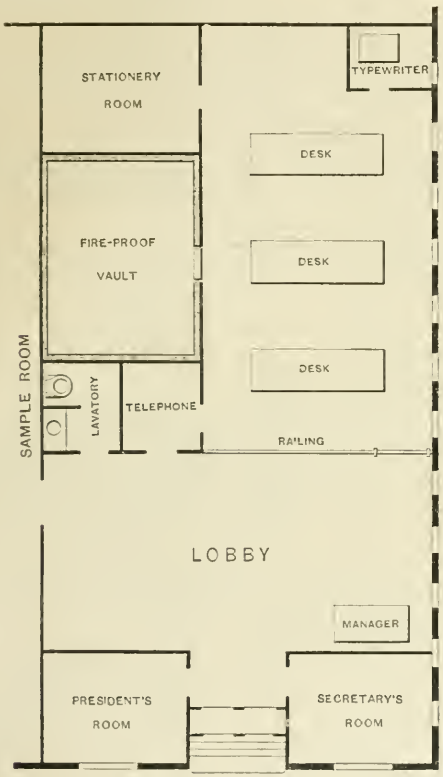
Mr. Littlefield came to Albany in 1851, and was with Treadwell, Perry & Norton for a few years; then with Erastus Corning from 1855 to 1861; then with Ira Jagger from 1861 to 1871, and since that time with his son, Henry C. Littlefield.

For years the Littlefield Stove Company occupied the old Warren foundry on Montgomery street, and when that property was purchased by the Central-Hudson railroad people, the present plant was established at the corner of North Pearl and Pleasant streets, where the company have been making stoves since 1870. From 1851 until 1872 the company confined themselves exclusively to manufacturing the Morning Glory parlor stove, double heaters and brick and portable furnaces. When the parlor stove patents expired Mr. Littlefield turned his attention to improving cook stoves and ranges, and to-day the extensive plant is taxed to its utmost capacity in turning out the large number of West Shore ranges needed. To show the popularity of this range it is only necessary to state that there are now over 5000 of them in use in Albany alone.

The molding room of the foundry is under the eye of foreman John G. Watkins, while Mason I. Croker has charge of the mounting department. The business office is in charge of Henry C. Littlefield, assisted by a force of clerks and traveling men.

The Brand Stove Company.

Some of the stove manufacturing concerns which have always been grouped among the small establishments have, within the past few years, grown with remarkable rapidity, and are now assuming considerable prominence in the trade. Among these may be named the Brand Stove Company of Milwaukee, Wis., whose works were started in a modest way, but have now grown so that they occupy almost the whole of a city block, while their sales extend throughout a very large part of the United States. They have come to the front, not only in their capacity for production, but also in the variety and quality of goods which they manufacture, now making almost every kind of stove demanded by the peculiarities of the trade. They turn out coal and wood cast-iron ranges, cooks and heaters, gas and oil stoves, hot air furnaces and steel ranges, but do not handle gasoline stoves. They have recently been giving more attention to high-class goods, and are putting out base burners of very handsome design to meet the demand for artistic productions in this line. Within the past year their facilities for the transaction of business have been increased about 50 per cent.



Plan of Offices of the Brand Stove Company.—Scale, 3-32 Inch to the Foot.

The works of the company extend 300 feet on Perry street, having a width of over 250 feet on Sixth and Seventh streets. Their mounting shop, nickel room, polishing room, &c., occupy a building 100 feet square, four stories high, with a basement. Some parts of the upper stories of this building are used for storage. The nickel room is of large capacity, and so well equipped that considerable outside work is done, as well as all the nickel work for the company's stoves. In the rear of this building is the molding room, which is 200 feet long by 100 feet wide, having a cupola in the center which melts from 15 to 18 tons daily. A new foundry is being built as an L, which will be 160 feet long by 75 feet wide. Pattern shop, fire-proof storage vault for patterns, engine room, fuel sheds, &c., are located in the center of the group of buildings, to which access is gained by convenient alleys. A new building has just been completed on the corner of Sixth and Perry streets, which is being used for offices, warerooms and storage purposes. This building is a very handsome structure, 150 x 102 feet, four stories high, with basement. It is built of cream-colored brick, on heavy cut-stone foundations, with large plate glass windows along the sample room on the first floor, and is most substantially constructed so as to easily carry the weight of an enormous stock of stoves. The sample room is 120 feet long by 102 feet deep, and is unusually well lighted, has a high ceiling, and is admirably suited to its purpose. A shipping room is located at the side of the sample room, which is 30 x 102 feet; two elevators run from the shipping room to the upper floors, which are connected by means of bridges across an intervening alley with the upper floors of the mounting shop.

The office, which is located in the northeast corner of the new building, is so handsome and so nicely planned that it is herewith illustrated. It is large, well arranged, finished with oak trimmings and oak ceiling, and is furnished with hard wood floors in the bookkeepers' department and private rooms, but with tile floor in the lobby or public part of the office. The entrance is by means of a recessed doorway, the vestibule being provided with double doors as a protection against cold weather. Private rooms are arranged for the president and secretary. The manager's desk is placed in the lobby, easily accessible to customers. The bookkeepers' desks are so arranged as to secure an abundance of light from the north. Lavatory and telephone rooms are placed very conveniently. In the rear of these is a large fire-proof vault, fitted up by the Hoffman-Keefe Office File Company of Milwaukee. The fitting consists of metal shelving, with rollers for the easy handling of heavy books; a large number of lock drawers and file cases, and separate locked compartments of large size for the use of each of the company's officers. This fire-proof vault is so large, being 10 x 12 feet in the interior, that it gives ample space for everything needing fire protection, and also includes a burglar-proof safe. The office will be lighted by electricity. It is heated by a large furnace in the basement. Separate fire places with artistic mantels are arranged in the officers' private rooms. All the appointments are first class in every respect, giving the officers and clerical force of the company accommodations of a superior order, very much beyond anything usually seen in connection with stove foundries. Sebastian Brand is president of the company, and devotes his time to the manufacturing details of the business. Julius Goldschmidt is vice-president, but is now in Vienna, Austria, where he has served for the past four years as Consul-General; he is expected home this summer, still retaining his interest in the company. Fred. G. Brand, the secretary, is at present residing at Colorado Springs, where he has been sojourning four months for the benefit of his health. E. W. Kasten is acting manager. D. W. Van Evera manages the Chicago branch.

The company now have five salesmen covering the territory from Ohio to the Pacific Coast, on the general product of the company. The eastern part of the United States is also covered by the operations of the company on oil and gas stoves. Gas stoves were sold in Sweden last summer through the medium of the company's advertisements in *The Metal Worker*. The Phillips & Buttorff Mfg.

Company of Nashville, Tenn., are general agents in the South for the company's oil stoves, which the Smith & Anthony Stove Company of Boston also represent as Eastern agents.

The Excelsior Steel Furnace Company

of 110–114 South Jefferson street, Chicago, Ill., have just issued from the press a complete and very interesting catalogue of heating specialties which they manufacture and sell. The volume is made up of 192 pages of letterpress, printed on good paper and profusely illustrated. It is bound in paper covers of a reddish-brown color, bearing as a gilt side title the single word "Excelsior." In bringing out this catalogue it has been the effort of the company to give to the dealer all information necessary for the intelligent handling of their specialties, while the work contains much special matter of value in this connection. In their announcement to the trade the manufacturers state that all their goods have been thoroughly tested and can be relied upon to do the work claimed when properly put in and operated. Particular attention is invited to a line of furnace fittings, which, it is claimed, are used by the leading furnace houses in the world, and are furnished at prices which cannot fail to be appreciated. The first thirty odd pages of the volume are devoted to a brief treatise on hot-air heating, numerous illustrations being presented in order to emphasize some of the points to which attention is directed. Following this is a chapter on furnace fittings manufactured by the Excelsior Steel Furnace Company, and which are carried in stock, ready for prompt shipment at all times. These fittings, we are informed, are made by special machinery designed by the company for the purpose. The material employed is said to be the best quality of bright IC steel stamping plates, of superior finish. The machinery is operated by power and the goods produced are claimed to be satisfactory in every respect. Illustrations are given of register boxes, bonnets and casing, safety thimbles, elbows and slip joint hot-air pipe, in connection with which is to be found ample descriptive letterpress. The next subject considered is the line of furnaces made by the company. These are carefully illustrated and fully described, the matter being presented in such a way as to render all points readily comprehensible. Tables showing the dimensions of the different styles and sizes of furnaces, as well as dimensions and prices of casings, form a feature of the catalogue. The Excelsior Unique Hot Water Boiler and the Excelsior Combination Heater are illustrated and described, following which is a chapter on radiators containing illustrations of several varieties, including the Brown Patent Improved Flue Radiators with all-cored surface. Another chapter gives attention to registers, while the catalogue closes with a list of heating specialties and sundries, either made by the company and controlled by them, or sold by the company as jobbers. An exceedingly interesting feature of the volume is a chapter entitled "Pointers," in which explicit directions are given to properly care for a furnace. The catalogue gives evidence of great care in the arrangement and preparation of the matter contained and will prove not only interesting, but valuable to all in the trade into whose hands a copy may come.

The Fischer Leaf Company of Louisville, Ky., favor us with a copy of a large catalogue which they have issued, showing marbleized iron and steel mantels, Eastlake and half low down grates, together with Eastlake half low down and portable grate baskets. The publication measures 9½ x 12½ nches in size and is bound in stiff board covers with gilt side title. This is the seventh catalogue which the company have issued and in it is presented a number of new designs of mantels. It is stated that in each mantel made by the company can be used the Brecher dumping and folding basket, for which many claims are made. The designs illustrated are of a varied character and cover a wide range of treatment. In connection with a sectional view of a mantel and grate are presented directions for setting the Brecher new patent basket, together with directions for laying tile hearths.

Old Stoves.

It is probable that many long established stove manufacturers occasionally hear of cases where certain of their stoves are continued in use much beyond the ordinary length of life of any good stove, and such items are always interesting reading to the trade.

It is probable, too, that the interest in antiquities which the World's Fair is apt to create has this year brought to light many such stoves, whose existence the manufacturer would otherwise never have known about.

The Union Stove Works lately received a letter offering them as an exhibit at the Fair one such old stove of their manufacture, and the letter, which speaks for itself, is given below:

Milt's Mill, Cal., February 13, 1893.
Messrs. R. R. Finch & Sons (the Union Stove Works), Peekskill, N. Y.:
Sirs: I have a No. 8 stove cast at your foundry, designed and patented in 1854. It was shipped to Crescent City, and in 1856 was bought for the small sum of $300 by my father-in-law and sent by mule back to me at Henley. The packing cost $50. This stove has been in constaut use ever since by me, and is a good stove today. I thought, perhaps, you might like to exhibit it at the World's Fair in Chicago. I have been in Siskiyou County since 1852, and am engaged in farming and quartz mining. My address is Coles P. O., Siskiyou Co., Cal.
Yours respectfully, Mrs. P. E. Milt.

The name of the stove, though not given in the letter, the firm know by the date of patent to be their Rival range. The letter would seem to indicate two things—that the Rival range was a good one and that Mrs. Milt has taken good care of it.

In thanking the lady, the company stated that it proved that their stoves, with good care, would last an ordinary lifetime; but they told her also that her stove was antedated by another of their manufacture, for which they had but a short while before furnished pieces to repair—namely, a stove made by them, called the Wood Cottage, and sold by them about eight years before the Rival.

Regulator for Gas Stoves.

A new regulator for gas stoves has lately been invented by Herr Porges of Vienna, and has been made by the firm of Robert Kutscher of Leipzig. According to an issue of the *Journal fur Gasbeleuchtung*, it depends upon the differing pressures of saturated vapor (that is, vapor in contact with its liquid) at different temperatures. A little closed metallic vessel contains a liquid which boils at a predetermined temperature, say 54° F. If the temperature of the room exceeds this the liquid begins to boil, the vessel dilates and works certain mechanism which shuts off the gas. The flames burn low until the temperature falls below 54° F.; then the liquid in the vessel condenses, the vessel itself returns to its former dimensions, and the gas again flows freely. But by the use of a regulating screw the tension upon the vessel can be modified, or pressure put upon it, so that the contained fluid will now boil at some other predetermined temperature. Then the room will have to attain the new temperature before the gas is shut off. In practice the flame comes to a size at which it is just able to keep the liquid in the vessel at the boil, and no more; so the flame remains of constant size (this size being larger in cold weather than in warm), and the temperature of the room is maintained uniform.

ODD PLATES.

The Cleveland Foundry Company, Cleveland, Ohio, have opened an Eastern office and salesroom at 82 North street, Boston, Mass., which is under the charge of Messrs. McMann & Brainerd, both of whom, we understand, are well and favorably known to the trade.

The Chicago Stove Works of Chicago, Ill., are sending to their customers a sheet printed in two colors, showing their new Gold Coin range. This is a six-hole construction, attractively ornamented and made in 12 different styles. We understand that it is meeting with a ready sale, and the company are confident that it is destined to be the most popular range ever brought out. The circular calls attention to many improvements and conveniences which are incorporated in the Gold Coin range.

Sam S. Utter and his wife are at present sojourning at the Hygeia Hotel, Fortress Monroe, where, we understand, they will remain several days. Mr. Utter has been giving very close attention to his business interests, and he deemed it the part of wisdom to seek a change of scene and air, together with a relaxation from business cares.

George M. Clark & Co. of Chicago state that the trade they are now doing in gasoline stoves and ranges exceeds anything ever experienced in the past. The demand is running very largely to new process stoves, although there is still a very respectable contingent of adherents to the old style single generators. If trade during the season keeps up to the current gain over preceding years, 1893 will be a banner year. The company have been obliged to greatly increase their teaming facilities in order to make shipments fast enough to satisfy their customers.

Evan A Edwards of Toledo, Ohio, has patented an oil burner or stove embodying several interesting features of construction. The burner consists essentially of a pair of parallel plates, one of which is provided with openings, the two plates being separated in such a way as to form a restricted air-draft space open on all sides between them and having a central oil feed. The lower plate is constructed with a central boss through which the supply pipe enters and projects beyond the apertured plate, and a surrounding oil receptacle or tank system of an absorbent material or a depression or both. Over the projecting end of the oil supply pipe is a vaporizing dome which rests upon the base and communicates with the second oil tank through spaces formed by serrations in its lower supporting end. The upper plate is supported by the base of the stove, the base having a bracket for holding the reservoir in convenient relation to the oil supply tube. The stove body consists of two concentric drums resting upon the base and forming a central combustion chamber over the burner. There is also a surrounding air flue open at the bottom for the free admission of air and a hot-air chamber between the drums at the top. This is supplied by the air flue, and has a restricted opening at the top. The combustion chamber has near its top an outlet with an upwardly-opening flue, formed by passing a pipe through the adjacent walls of the two drums and terminating at the opposite wall of the inner drum, an opening being made in the upper side of

the pipe. The effect of this particular form of body, the inventor states, is to supply pure air through the air flue to the hot-air chamber, causing it to linger until heated and thus facilitate the heating of the air in the chamber by insuring the impact of the gas and the products of combustion against the top of the chamber, which forms the bottom of the hot-air chamber, before they can escape.

THE HOWARD FURNACE COMPANY, now at 254 Water street, New York, have leased a portion of the premises at 210 Water street, where they hope to see their friends after May 1. They will have one-half of the office and showroom floor, the cellar for storage, and the top loft for shop work in connection with their hot-water and hot-air furnaces, giving them facilities for setting furnaces anywhere in New York or vicinity. They are about to bring out a new line of furnaces, including hot air and combinations of hot water and hot air, both brick set and portable. They expect to carry 10 to 12 carloads of these goods and are arranging for handling a largely increased business.

THE PUBLICATION in these columns a week or two since of a novel advertisement has called out a letter from Miles Strevell & Ulmer of Ogden, Utah, in which they inclose a transfer ticket for use on the Ogden City Street Railway Company. We understand that the firm have furnished the railway company with 23,000 of these tickets, one side of which is lettered and marked in the usual manner of documents of this character, while upon the other side is the name and address of the company, a *fac simile* of the Garland trade mark, and the statement that the firm deal in hardware, culinary appliances, stoves and ranges, lawn mowers, sprinklers, garden hose, &c. The firm have in each street car a Garland heater with a fine, large nickel name plate inscribed "Miles Strevell & Ulmer, Ogden, Utah." This brings the name Garland before the eyes of hundreds of people every day and constitutes a decidedly effective advertisement.

THE MAGEE FURNACE COMPANY of Boston, Mass., state that the sales of the Magee Boston heater have increased every year since it was first introduced into public use in 1884. None but the best materials and the highest grade of skilled labor are employed in its manufacture and every furnace is warranted to give entire satisfaction in every respect if properly put into use. The company have branches at 242 Water street, New York, 86 Lake street, Chicago and 27 New Montgomery street, San Francisco.

THE ART STOVE COMPANY of Detroit, Mich., have just completed for this year's trade a new base heater for soft coal or wood, which is confidently expected to prove a valuable addition to their already extensive line of stoves and ranges. The new heater has been designed with a great deal of care, is artistic in its decorative features, and will be known under the name "Parlor Laurel." The manufacturers inform us that there will be found many points of improvement over the old style of stoves, and it is in more than one way a new departure in this class of goods. We have a four page circular bearing illustrations of the Home Laurel range, which has recently been placed upon the market. It is a six-hole construction of a high order of merit, and is ornamented in a pleasing and artistic style. The picture on the first page of the circular is reproduced directly from a photograph of the stove.

THE KERNAN FURNACE COMPANY, of Utica, N. Y., propose erecting a new plant for which Architect James Constable, Jr., has already completed the plans. It is to be located on the north bank of the canal, just west of Clay street, in East Utica, upon the plot of ground recently purchased by the company for the purpose. It is expected that the contracts will soon be let and that the work will be commenced at an early day. The plans call for a most complete and convenient plant, which will be under one roof of graveled asphalt, 468 feet in length. The dimensions of the mounting room will be 60 x 161 feet on the ground and 13 feet 10 inches in the clear. The roof will be supported by wooden posts. The mill room will be 40 x 80 feet on the ground and 13 feet 10 inches in the clear. The molding shop will be 67 x 204 feet on the ground and 28 feet in the clear. The roof will be supported by 60 foot trusses. Leading from the molding room will be the cupola or melting room, 20 x 36 feet. The upper floor about the cupola will be supported by iron girders. The carpenter shop will have ground dimensions of 20 x 32 feet each. Under the floor of the molding room will be a tank of 14,000 gallons capacity in which will be stored the water running from the roof. A switch from the New York Central and Hudson River Railroad will run the full length of the plant. The cupola will be 6 feet in diameter and 35 feet in hight. The plant will be built on the mill-construction plan. The floor, consisting of sleepers resting in ashes, will be laid with pine boards dipped in tar, with matched spruce boards laid on top. The company are now considering the project of increasing the capital stock from $20,000 to $50,000. With the new plant the company will be admirably equipped for their extensive and constantly growing business.

A HOT AIR HEATER having converging air-heating flues over the combustion chamber, and means for heating the sides and rear of the device so as to provide additional surface for warming the cold, and also fresh air, forms the subject of a patent granted to William J. Jackson of Philadelphia, Pa.

RATHBONE, SARD & CO. of Albany, N. Y., have just issued a handsome 12-page special catalogue of Acorn ranges. The covers are of orange, handsomely printed in black, and the central ornament is the familiar acorn trade mark. The pages are finely printed in black and carmine and are well illustrated. The advantages of the Acorn range are set forth in the pages while the National Acorn is illustrated, as well as its system of oven ventilation and the "removable grate bars" feature. The Penn Acorn, the popular range, the Home range and the Duplex Acorn are shown by engravings, as well as the Eureka and Citizen ranges. The whole is most artistically gotten up and will prove interesting to the trade.

THE EXCELSIOR MFG COMPANY of St. Louis, Mo., have just placed upon the market a new wrought steel range known as the Monarch. In offering this construction the company say that they do not withdraw any of their claims heretofore made, that the Charter Oak cast iron range is far more desirable in point of operation and lasting qualities than any wrought steel or wrought iron range that has ever been, or will be, produced, but that the Monarch is the best wrought-steel range made. It is claimed to embody all the most desirable features of the best steel ranges heretofore offered, is well made of the best material, and by men who are skilled in this class of work. The circular which the company have issued illustrating and describing this stove bears an announcement in the closing paragraph of which we find the following: "In anticipation of our being asked why we have not added the valuable feature of the wire gauze oven door to the Monarch, we will say the inventor of the gauze door, who is also the inventor of the Charter Oak stoves and ranges, desires the Charter Oak alone to have the advantage of the gauze door, which makes the only 'specialty' in the way of a cooking apparatus on the market, and far ahead of any stove or range."

THE RAYMOND & CAMPBELL MFG. COMPANY, Middleton, Pa., contemplate making several changes in their line of stoves and ranges. They are redressing their Grand Perfect in a very neat and handsome style, and are confident that it will prove popular with the trade. They are also introducing a large oven range having a capacious ashpit, and adapted in its general make up for the New York and Western trade. This range will be known as the Model Perfect. For the purpose of augmenting their line of heating stoves they have just completed patterns for three sizes of a very attractive, yet cheap, square stove to be called the Perfect. It is the expectation of the company to have ready by May 1 a square stove of a higher grade. We understand that some changes and additions are also contemplated in connection with their line of egg stoves. The company are now giving employment to 180 men, and have been running their factory full time for some years with the exception of a few stoppages for repairs, stock taking or other special purposes.

IN THESE COLUMNS a week or two since we presented a *fac simile* of a rather unique advertisement made use of by the firm of Evenson Brothers of St. Peter, Minn. In connection with this matter our readers may be interested in knowing how the author of the advertisement referred to conducts his system of advertising. The first of the year he purchased for 12 months, a number of inches of space in the different local papers, to be used in single or double column as may be desired. One week an advertisement like the one presented in *fac simile* in these columns a short time ago is used and the following week the space is occupied by a short story, which winds up with a reference to the firm named.

THE BOYNTON FURNACE COMPANY, 195–197 Lake street, Chicago, are making a number of changes in the arrangement of the first floor, putting themselves in order for the better entertainment of visitors this summer to the World's Fair city. The office has been removed to the rear, thus affording ample space in front for the display of heaters and ranges manufactured by the company. On a platform near the front windows are placed three heaters, which being painted red, white and blue present a patriotic appearance.

A HEATER FOR FIRE PLACES which shall economize in the amount of fuel consumed yet will produce from a given amount of fuel an increased quantity of heat, has been patented by Albert E. Lytle, of Chicago, Ill. The device is so arranged that with slight modifications it is applicable to stoves, furnaces and the like and is arranged to supply rooms with fresh pure air, rendering it wholesome and healthful by the addition of moisture or a limited amount of steam. The inventor claims that by the arrangement of parts a number of rooms may be furnished with heat from the same grate or fire. Mr. Lytle has assigned his interest in the patent to Simeon D. Overtt of Chicago.

THE HOWARD THERMOSTAT COMPANY, Syracuse, N. Y., have recently opened a branch at 166 Upper Thames street, London, England, for the purpose of pushing the sale of their Thermostat, which has met with such success in this country. This device is designed for regulating the temperature of buildings at any desired point in connection with house or other furnaces. They have secured letters patent in Great Britain, and the United Kingdom will be thoroughly canvassed by travelers and the sale of this article pushed in every way.

TRADE REPORT.

The Iron Market.

The condition of the Iron market in different parts of the country has not been of a uniform character during the past week. In Eastern markets a somewhat improved condition of trade prevails, which is equally true of some portions of the West. Chicago and Southern markets show less encouraging features, both in the volume of demand and in the matter of sustaining prices. Eastern markets are showing a greater activity and also more of a uniform steadiness. No especial weakness in prices is noticed, while in some cases they are a shade better and in others steady to firm. There is nothing to cause any buoyant feeling, but it is something to note that there is less depression, and at least a semblance of improvement. Whether this will be carried any further or not is for the future to determine. The starting point of the improvement appears to have been in Bessemer Pig, from that to Steel Billets, and so on to material in its more advanced condition.

The trade are now waiting to see what the future developments will be, more especially in Ores, Pig Metal and Billets. The next movement in these will probably decide the course of the general market for some time to come. Finished Material is already too low compared with the price of Billets, and, as these are developing increased strength, manufacturers of Plates, Shapes, &c., will be compelled to stiffen their prices in proportion. The question in the meanwhile is whether the movement is genuine, or whether it is a little spurt.

The true inwardness of the thing will have to be developed naturally. There is no such thing as speculation these days. What a consumer needs will be bought, what is not needed (in a speculative sense) will not be bought. Hence all will depend upon the actual relation of supply and demand. Judging from the course of events during the past couple of weeks, it may be assumed that a further moderate improvement is not improbable, and in any case there is very little prospect of a relapse to the low figures quoted a month or six weeks ago. Meanwhile, as we said before, consumers are in no mood to buy very far in advance of requirements, although in some instances prices are quoted lower on that class of business than for deliveries within 30 to 60 days.

In the Pittsburgh market, developments in the Iron and Steel trades within the past week indicate that the situation has considerably improved within the last month. Commencing with Pig Iron, it can be stated that Bessemer is in fair demand with a majority of furnaces refusing to sell at less than $13.50. The Steel market is in excellent shape, with mills well sold ahead and prices about $1 per ton higher than a month ago and a probability of still further advances before this month is out. Plates and Structural Material are in better demand, with no improvement in prices. Rods, which have been dull and neglected for some time, are looking up, with a better understanding among makers regarding prices than has existed for some time. Wire and Wire Nails are undoubtedly in the lead as far as improvement in demand and prices is concerned. An advance of fully 15¢ per keg in Wire Nails has occurred, while Plain and Galvanized Wire is from $2 @ $3 per ton higher. Connellsville Coke is also reported as slightly improved in price. In Merchant Steel and Pipes and Tubes the situation is not satisfactory, but now that spring trade has opened up so auspiciously an improvement in demand and prices for both is probable. It will then be seen that the situation as a whole shows considerable improvement, particularly as regards tonnage, and, while prices on some lines are very close to cost, there has been some improvement in this direction with prospects of further betterments in the near future.

The threatened strike of all the switchmen on the railroads at Chicago has been postponed. A conference was held Monday between railroad managers and representatives of switchmen, at which the latter withdrew their demands and stated they would not press them until some time in future when railroad earnings were improved and the demand for higher wages would seem more reasonable All classes of business men hope that this menace to Chicago business has been removed. The delivery of freight is still retarded by other inconveniences and the event of good weather, which was expected to improve the situation, has as yet made very little difference. Complaints are very numerous over the non-arrival of freight from Eastern points, which has been on the way for a month or more. Inadequate motive power, scarcity of cars and the very heavy movement of freight are the principal reasons assigned for the trouble.

In Southern markets there has been but a moderate volume of business in Pig Iron during the week, and the tone of the market is anything but strong. There is no quotable change in prices, but rumors of concessions having been made are numerous, and when sifted down it appears that it was by some furnaces which are so situated that they have the advantage of a lower freight rate than that from Birmingham. There are abundant offerings of Iron for almost any delivery this year, but buyers seem to prefer to buy only for short delivery, say three or four months ahead, thinking that any probable change in the market will be in their favor. All sales stipulate for prompt delivery, and there are urgent applications for prompt delivery on previous contracts, showing that buyers are not allowing a sufficient margin for ordinary vicisaitudes in making their purchases.

Sellers report more activity in the New York Pig-Iron market, and quite a number of large transactions, both in Northern and Southern Iron, are reported to have been closed during the past week. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14 25 @ $14.75 for No. 1; $13.25 @ $13.75 for No. 2 and No. 1 Soft.

The Philadelphia Pig-Iron market, without being strong, is firm and steady. The best brands are well taken up, and at the moment there is not the slightest appearance of weakness in any direction, although makers are not bold enough to hint at even a trifling advance. In the event of a round lot of several thousand tons a buyer would require special inducements, but the offerings of this kind are either very few, or they are closely guarded, as we hear of nothing at less than $12.50, Philadelphia, and in some cases consumers find it difficult to secure anything worth while even at that figure. Taking the market as a whole, it may be said to be steady at unchanged prices, with a good demand, and also a pretty good supply—one about balancing th other.

The increase in the output, as shown by the last monthly statement, is at the rate of about 5000 tons per week, which for the time being, may have a tendency to check any upward movement in prices.

Sales usually at prices about as follows for Philadelphia and equivalent deliveries, with 25¢ to 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$17.00	@ $17.25
American Scotch, No. 2X.....	16.00	@ 16.25

The demand for local Coke Iron at Chicago fell off considerably during last week and the general Pig Iron trade has therefore been comparatively quiet. The price on No. 1 Local Coke has for some time been relatively low as compared with other grades, resulting in very heavy business, which led to such scarcity that manufacturers have found it expedient to advance prices about 50¢ ₱ ton. Quotations are revised accordingly. Southern Coke Iron

has sold a little more freely, but not in sufficient quantity to make trade active. Competition among sellers of Southern Irons is very keen and all transactions are still being made at cut prices. No. 2 Foundry and No. 1 Soft are known to have been sold at least 25¢ below our quotations. Lake Superior Charcoal remains quiet but steady at old rates. We revise our quotations as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50 @ $17.00
Local Coke Foundry, No. 1	13.75 @ 14.25
Local Coke Foundry, No. 2	13.00 @ 13.25
Local Coke Foundry, No. 3	12.75 @ 13.00

In Southern markets there appears to be something out of joint in the Iron trade, for in spite of the reported reduction in stocks and the large consumption which is evidently in progress, all changes are in the direction of lower prices. In fact the entire line is in a partially demoralized condition from which it seems impossible to extricate it. Furnacemen claim to be selling Iron at cost, and we know of one or two cases where preparations are in progress to "blow out." This seems to be the only solution of the question. Stocks of Iron on the furnace banks are large and increasing, and the immediate future does not contain anything of an encouraging nature, so that there is no inducement to continue, whereas to "blow out" seems the only thing to do. Quotations unchanged.

Foundry.	
Southern Coke, No. 1	$13.25 @ $13.50
Southern Coke, No. 2	12.00 @ 12.25
Southern Coke, No. 3	11.25 @ 11.50
Ohio Soft Stone Coal, No. 1	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2	15.00 @ 15.25
Mahoning and Shenango Valley	14.75 @ 15.00
Hanging Rock Charcoal, No. 1	19.00 @ 19.25
Hanging Rock Charcoal, No. 2	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @ 14.75

Metal Market.

Copper.—There have been no new developments the past week in the market for Ingot. Buyers manifest the same indifference and reserve that they have displayed since the beginning of the year, while sellers maintain a remarkable exhibition of firmness, considering the somewhat adverse circumstances against which they have had to contend. Present appearances are that the market would be in a thoroughly demoralized condition at the present time had not the scheme of restricting production been carried to a successful issue. As matters stand, it seems difficult to market outside lots at prices ⅛¢ below the minimum rates quoted by the producers. About 11¼¢ @ 12¢ for Lake Superior Ingots and 10¾¢ @ 11¢ for common Casting Copper would appear to fairly reflect market value at the moment. Late on Wednesday there were rumors of sales having been made to consumers at 11⅛¢ for Lake Superior Ingot and 10¾¢ for common Casting Copper.

Pig Tin.—The advance in prices that was established at the close of the period covered by last week's review has been followed by a reaction of about ¼¢ ₱ lb in the face of higher average quotations from London. Official records show transactions in the meantime involving several hundred tons, and it was rumored that quite as much, or more, Tin changed hands privately in a speculative way. There was some diversity of opinion regarding the volume of movement into the channels of consumption, but evidence was mostly to the effect that the distribution will lose nothing by comparison with the average for this season of the year. That this should be the case is not surprising in view of the fact that several holders have, directly or through convenient agencies, urged their customers to stock up before the proposed 4¢ duty goes into effect, and thus prevent the transfer of neat sums of money from the pockets of the consumers to those of the importers during the next three months. Evidence is wanting, however, of anxiety on the part of those operators to buy more Tin than they are inclined to sell, despite the glowing arguments they present for others to buy immediately and freely. Shipments from the Straits during first half of March were advised as having been 1500 tons to Great Britain and America, and 150 tons to the Continent. There was a sale on the Metal Exchange on Wednesday of 10 tons for April delivery, at 21.05¢. Bids of 21¢ were made for March and April, and 21.10¢ for May and June.

Pig Lead.—Prices have been held quite firmly at the higher level established last week, but buyers have manifested extreme indifference, as though perfectly content to let the future take care of itself, and confident in the opinion that supplies will be quite full enough to meet the demand. Hence a quiet, although apparently firm, market at the present time, with the range of 3.90¢ @ 3.95¢ quoted for carload or larger lots.

Spelter.—There are liberal offers from the West to sell for April and later shipment at 3.97½¢ there. At present rail freight that price is equivalent to 4½¢ @ 4.27½¢, delivered in the East. Few orders have passed through this market at the rate named, however, and Eastern buyers seem disinclined to purchase at all freely until after the opening of navigation. Spot stock is quoted at 4.30¢ @ 4.35¢, according to size of lot.

Antimony.—Demand has been only fair. Prices have shown some little irregularity, yet no radical change. Current quotations are 10¢ @ 10½¢ for Hallett's, 10½¢ @ 10¾¢ for LX and 10½¢ @ 10¾¢ for Cookson's.

Tin Plate.—Slightly higher prices rule for ordinary Cokes on the spot, and the foreign market for that class of Plate is firm also. Very fair sales have been made, but nothing transpired in the way of unusual dealings. Ternes are somewhat lower, as are Wasters, with only a moderate business passing. Bright Charcoals without change in price and selling rather slowly. In a retail way there is no change in prices and but a small increase in demand. The recent cold and more recent rains have brought to notice weak points in gutters, spouting and roofs, which will have to be repaired, thus filling the gap before new outside work is ready.

Coal.

The Coal sales agents, at their meeting in this city on Tuesday, made a substantial drop in prices, to take effect at once. The comparison of spring opening prices for two years stands as follows, all f.o.b :

	Free Burning.	Broken.	Egg.	Stove.	Chestnut.
1892		$3.65	$3.75	$3.90	$3.65
1893		3.90	3.90	4.15	4.15

A more active movement will be expected, now that consumers have no motive for holding off for a break. There is plenty of Coal of all sizes except Pea and Buckwheat. Spot cargoes may be quoted as follows : Pea, $2 50 @ $2.75 ; Buckwheat, $2 @ $2.15. The trade are much interested in the election of directors for the New England road, held on Tuesday, showing that McLeod is "on top" and will have much influence on prices.

A dispatch from Pottsville says that 17 collieries in that section were closed by the floods.

The Bituminous Coal market has "no starch" in it, there being Coal in abundance, and sellers are competing to an extent that makes prices very irregular. Some sales are made at the lowest mark. The big contract for the Long Island Railroad, to be closed at once, excites much curiosity, for the terms agreed upon, if they can be ascertained, will to some extent control other contracts to be renewed at this season. There is also a question about railroad tolls for the coming year. The association prices take effect in April.

The amount of Anthracite shipped from the mines last week was 884,000 tons, an increase of 173,500 tons compared with the same week last year. The comparison since January 1 is about the same for the two years.

The Pennsylvania Railroad Company is about to order 2000 Coal cars, which will cost nearly $1,000,000.

Financial.

The currency situation operates to discourage expansion in trade, but confidence is felt that a wise course will be pursued by the Government in seeking to extricate itself from present difficulties. Perhaps the least satisfactory of all is the continuance of enormous imports, but the amount of produce awaiting shipment is so great that a change for the better in the relative amount of exports must soon take place. The total imports at the port of New York for February, exclusive of specie, is $52,000,000, an amount nearly $8,000,000 in excess of the corresponding month last year, which up to that date was the most active February in the history of the past. The shipments, on the other hand, showed a marked decline in the total of produce and merchandise for the month, $22,769,856, which is $8,000,000 below the corresponding total of last year, and is less than any previous total for a similar period since 1887. Touching the future augmentation of exports, the report of the Agricultural Department just at hand confirming suspicions that estimates made heretofore of the last yield

of wheat were to low by 31,000,000 bushels, is hopeful. The extraordinary receipts from farmers' hands during the winter are thus partially explained.

The demand for sterling exchange and higher rates for money, led to a sharp decline in rates. The selling of stocks for London failed to check the drooping tendency. Posted rates were $4.86½ @ $4.88½.

Bar silver closed in London at 38 5/16d. per ounce. The commercial price of bar silver in New York was 83¼¢ per ounce.

The first steps toward a permanent organization of the transcontinental lines were made by the freight agents in session in Santa Barbara, Cal. They agreed to form an association to be called the "Transcontinental Freight Rate Committee," in which all transcontinental lines except the Great Northern, Northern Pacific and Canadian Pacific will be parties.

The general markets were quiet owing to quetions in finance, stringent money and unfavorable weather. The Treasury was understood to be in an easier position, but Mr. Carlisle was reported to have resolved to say little respecting the policy to be adopted, choosing rather to act as the best interests of the public may seem to demand. The wheat market was again lower, May wheat touching 77⅛¢, the lowest point on the crop. Corn also declined. Provisions dull, cotton without change. Coffee very dull.

Chicago Report.

Scrap.—Dealers report Cast Scrap in good demand but Wrought very quiet, and quote the following nominal buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....

CONDITION OF THE

Hardware Trade.

THE HARDWARE MARKET throughout the country is characterized by a fair activity, and in some sections the demand is exceptionally good. Trade has to a certain extent been held back in some parts of the country by floods and severe weather, which have had the effect of considerably diminishing the activity. All the indications point to an excellent demand as the season advances, with the prospect of a large trade during the next few months. In some lines, such as Nails and Barb Wire, there is an improvement in the tone of prices, and in some other goods also there is a reaction from extremely low quotations. Shelf Hardware in general remains without important change, except in a few lines, to which reference is made below. The most important advances which have taken place are in Augers and Bits and Jack Chain. The new Cut Nail card is in general use, and while, on the whole, meeting with approval is criticised by many in the trade. The feeling in regard to this is reflected in the correspondence published on another page. Manufacturers as a rule are well occupied on orders, and in some lines there is difficulty in obtaining goods as fast as called for by the trade. With this heavy demand it is matter of surprise that more strength is not shown in prices, for in some lines, where manufacturers are more or less behind their orders, prices are low and demoralized. Some difficulty is experienced in collections, which are especially slow in some sections.

Advices from Chicago.—Heavy Hardware is in much better demand, and consumers of all kinds are ordering liberally. The city trade has picked up considerably of late, while Nail orders from the country are much in excess of what they were two or three weeks since. The demand for Bar Iron and Steel from stock is especially large, and stocks have to be frequently replenished.

Shelf Hardware has also improved, but the volume of trade in this line is still below what it should be for March.

The country roads are now in extremely bad condition through the West, mud blockades being reported from nearly every quarter Inundations in Western rivers and ice gorges are seriously interfering with operations of railroads further West, and thus restrict trade below its seasonable proportions. Jobbers here are looking forward to an exceedingly good trade this summer, as foreshadowed by advices from their traveling men. Merchants all over the West expect to visit the World's Fair this summer, and will defer heavy purchases as much as possible until they can attend to their trade here in person.

The Brass houses report an unusually heavy demand. The managers in some cases say they were never before so busy as they are now. Prices on Brass goods are somewhat stiffer on large quantities, but the advance has not yet affected smaller lots. Collections have not improved, and the financial outlook, therefore, continues rather discouraging.

Notes on Prices.

Cut Nails.—The Cut-Nail Market is in substantially the same condition as last week, and prices are quite regularly maintained on a basis of $1.25 for carload lots, f. o. b. factory, but concessions are made in some cases. Manufacturers, without exception, as far as heard from, are using the new card and are making their quotations from it. It is also in general use throughout the trade, though some houses have not yet adopted it. Carload lots on dock are quoted at $1.40, and the usual advance is made on small lots from store.

Advices from Chicago.—A very fair trade is reported by manufacturers of Cut Steel Nails. New contracts have recently been coming in better. Specifications are being freely made on old contracts, and shipments from the local factory are now very heavy. Prices are unchanged at $1.42½. Chicago, for carload lots on the new card. Small lots from stock are selling at $1 50.

Wire Nails.—The recent advance in the price of Wire Nails has had the effect of checking purchases to some extent, but the demand is referred to as fair. The volume of business during the past month or two was exceptionally heavy, and the prospect for a large business during the remainder of the season is excellent. Prices are characterized by a firm tone and are strictly maintained on a basis of $1.50, f.o.b. factory, Cleveland being the point of equalization for the West and Pittsburgh for the East. Small lots from store in New York are quoted at $1.75 to $1.80.

Advices from Chicago.—Manufacturers of Wire Nails are in session here with representatives reported in attendance from all the factories of any consequence. Members of the trade who have been interviewed state that the Wire-Nail business this spring has been phenomenally large. Specifications coming in on contracts taken would clean out the warehouses if it were possible to get enough cars to make prompt shipments. They look forward not only to a maintenance of present quotations of $1.65, Chicago, from factory, but feel confident that better prices will prevail before long. There is some reason to believe that a new Wire-Nail card is in course of preparation. Jobbers have been taking some of the business that usually goes to manufacturers, but they are now apparently convinced that higher prices will be maintained and are making their quotations for carload shipments on the same basis as manufacturers, or a trifle higher. Some of them have been cutting this rate and giving their customers the benefit of low purchases made some time ago. The situa-

tion has decidedly improved of late and the sanguine views of manufacturers seem to be well founded. Small lots are selling from stock here at $1.70.

Barb Wire.—The volume of business is good and prices are firm. Without any quotable change the market is characterized by a better tone and more regularity. In the present condition of things, with the good understanding prevailing among the manufacturers and the increasing demand, it would not be surprising if somewhat higher prices prevailed. Quotations are on the basis of $2.40 @ $2.45 for carload lots of Four-Point Galvanized at mill. Small lots from store in New York are held at $3.10, an abatement of 10 cents being made in carloads.

Advices from Chicago—Manufacturers of Barb Wire are now in session in this city, and it is possible that before they adjourn they will make an advance in prices. The condition of trade has so greatly improved of late that, while the price of steel has also advanced, the conditions are believed to be opportune for an upward movement of quotations on Barb Wire. The cheap stocks in jobbers' hands have also been so nearly exhausted that little is now heard of their competition with manufacturers. Quotations from factory are still $2.20 and $2 60 for carload lots of Painted and Galvanized respectively, while jobbers are quoting $2.35 and $2.65 for small lots.

Tackle Blocks.—The Tackle Block market continues to be characterized by much irregularity and low prices are being quoted. Toledo Block Works, Toledo, Ohio, advise us that their present price on regular blocks is 80 per cent. discount, f.o.b. Toledo, and we understand that other manufacturers are making a similar price.

Discount Sheet.—William Johnson, agent, Newark, N. J., issues a revised discount sheet to apply to his catalogue B, 1890, together with supplementary sheets of additional goods. The line of goods manufactured and illustrated in this catalogue includes carpenter tools, Plumbs and Levels, Saw Sets, Pinking Irons, Garden Trowels, Tinners' Hammers, Blacksmiths' Tongs, Plumbers' Tool Bags, &c.

Screen Doors, Window Screens, Etc.—We give below quotations on Screen Doors, Window Screens and Window Screen Frames, manufactured by A. J. Phillips & Co., Fenton, Mich. As the company deliver to many points, and as the freight is an important item, there is necessarily considerable variation in their prices in different parts of the country. Those named below fairly represent the prices at which the goods are sold·

	Per cent.
Phillips' Screen Doors	50 @ 50–5
" Fancy Screen Doors	50–10 @ 50–10–5
" Bonanza and Perfection Window Screens	50–5 @ 50–10
" Extension Window Screens	50 @ 50–5
" Window Screen Frames	50 @ 50–10

Augers and Bits.—The manufacturers of Augers and Bits have during the past week been in conference, with a view to forming an association which would put this line in a more satisfactory condition and correct the demoralization and unprofitably low prices which have characterized the market in these goods for some time. As the result of their deliberations an organization entitled the AUGER AND BIT ASSOCIATION has been formed, composed of the following manufacturers:

SNELL MFG. COMPANY,
JAMES SWAN,
JENNINGS & GRIFFIN MFG. COMPANY,
ROCKFORD BIT COMPANY,
HAMDEN MFG. COMPANY,
NEW HAVEN COPPER COMPANY,
HUMPHREYSVILLE MFG. COMPANY,
CONNECTICUT VALLEY MFG. COMPANY,
PECK, STOW & WILCOX CO.
CHESTER MFG. COMPANY.

JOHN H. COMER, of the New Haven Copper Company, New Haven, Conn., was chosen president, and W. C. SMITH, president of the Rockford Bit Company, Kokomo, Ind., vice-president.

The firms named above are, it will be observed, the leading manufacturers of the following lines: Double Twist and Side Lip Cast-Steel Auger Bits, Cast Steel Nut Augers, Boring Machine Augers, Millwright Augers, Short and Long Eye Augers, Cuban Augers, Long Rafting Augers, Post Augers, Short Bright Augers, Long Bright Augers, Cast-Steel Car Bits, and Jennings' Pattern Auger and Car Bits.

As the result of the conference a strong organization was formed with a view to maintaining prices on an equitable basis which will afford a fair margin of profit and put an end to the extreme competition and cutting of prices which has been a feature of the business for a long time. It was of course deemed necessary to make an advance in the goods, and the following revised prices are announced:

	Per cent.
Common Auger Bits	70
Nut Augers 1 to 2¼ inch, inclusive	70
Boring Machine Augers	70
Nut Augers over 2¼ inch	50 and 10
Millwright and Rafting Augers	50
Short and Long Eye and Cuban Augers	50 and 10
Short and Long Bright Augers	50 and 10
Post Augers	50 and 10
Double Spur Car Bits	50
Jennings' Pattern Car Bits	40
Jennings' Pattern Auger Bits	60
Snell's Bits	60 and 5

Revolving Table Bell.—This article is manufactured by the Hardware Specialty Company, for whom C. F. Guyon Company, 99 Reade street, New York, are agents. The list is as follows, subject to a discount of from 50 to 50 and 10 per cent.:

	Per dozen.
3-inch Nickel Plate	$26.00
4 " " "	32.00
3 " Quadruple Silver Plate	36.00
4 " " " "	48.00

Machine Bolts.—The Machine Bolt market is irregular and prices are ruling somewhat lower than a few weeks ago. Some of the manufacturers are refusing to meet the extreme quotations of their competitors. The volume of business is excellent, and there is some complaint of delay in filling orders.

Jack Chain.—The manufacturers of Brass and Iron Jack Chain, Safety Chains, Plumbers' Chains, &c., have adopted a revised list, which is printed below. The object of the revision is to correct inequalities in the list which has been in use for more than 20 years, the former list having been adopted January 1, 1870. At the same time an agreement was reached in regard to discounts, the result of which is something of an advance on prices which have recently been ruling. The revised list, which bears date March 9, 1893, is given below, and is subject to a discount of from 50 to 50 and 10 per cent.:

Jack Chain.

Per Box, 12 Yards in Each Box.

No.	Brass Single.	Brass Double.	Iron Single.	Iron Double.
5	$8.00	....	....	....
6	7.00	....	$1.60	....
7	6 60	....	1.40	....
8	5.70	....	1.30	....
9	5.00	....	1.20	....
10	4.00	$4.50	1.00	$1 30
11	3.30	3.70	.80	1.10
12	2.40	3.20	.70	1.00
13	2.00	2.60	.60	.90
14	1.50	2.00	.50	.80
15	1.10	1.60	.40	.70
16	.90	1.40	.36	.60
17	.70	1.20	.32	.50
18	.60	1.00	.30	.44
19	.54	.90	.28	.40
20	.50	.80	.28	.40
21	.44	.70	.26	.38
22	.40	.60	.24	.36
23	.40	.60	.24	.36
24 and smaller	.40	.60	24	.36

For tinning Jack Chain, the following net additions are to be made to the net price of Jack Chain which is to be tinned:

Nos. 15 and 16.....add 5 cents net.
" 13 " 14..... " 6 " "

For nickeling or silvering Jack Chain, 25 per cent. net is to be added to the net price of brass Jack Chain of the number nickeled or silvered.

Safety Chains.

Per Box, 12 Yards in Each Box.

No.	Brass.	Silvered.	Nickeled.
000	$1.20	$1.35	$1.45
00	1.30	1.45	1.55
0	1.50	1.65	1.75
1	1.80	1.95	2.05
2	2.40	2.55	2.65
3	3.60	3.75	3.85

Plumbers' Chains.

Per Box, 12 Yards in Each Box.

No.	Brass.	Silvered.	Nickeled.
00	$1.05	$1.20	$1.30
0	1.25	1.40	1.50
1	1.65	1.80	1.90
2	2.05	2.20	2.30

Plumbers' Chains.

Per 100 Feet, on Reels Containing 500 Feet.

No.	Brass.	Silvered.	Nickeled.
00	$2.85	$3.30	$3.55
0	3.40	3.85	4.10
1	4.60	5.05	5.30
2	5.70	6.15	6.40

Cordage.—An advance has been made in the price of Sisal Rope, which is quoted by the National Cordage Company at 7¾ cents, an advance of about ½ cent on former quotations.

Star Lawn Rakes.—The Star Lawn Rakes, manufactured by Syracuse Specialty Mfg. Company, Syracuse, N. Y, for whom Surpless, Dunn & Alder, 97 Chambers street, New York, are agents, are quoted at the following prices:

	Per dozen.
Star Self-Cleaning Rakes	$5.50
Star Plain Rakes	5.00

Economy Saw Vises.—These goods, which are manufactured by Syracuse Door Hanger Company, Syracuse, N. Y., are quoted at the following prices, subject to a discount of 50 and 10 and 10 and 5 per cent.:

	Per dozen.
No. 110, 9½-inch Jaws	$10.00
" 120, 10-inch " self-opening, extra heavy	15.00

Glass.—While there is no perceptible increase in the local demand for Glass, the market on American Glass is firm, and the outlook encouraging. The nearer approach of weather when building operations can be resumed, and the absence of any building trade troubles at the present time, are conditions favorable to a larger demand in the future. Reports indicate that stocks are low in makers' hands, and that the movement in Glass is active. There has been no change reported in the National Window Glass Company's prices, and these are being adhered to by members of the association, as far as heard from. The French Window Glass market continues in an unsatisfactory condition, as no agreement as to sustaining prices has been reached. The condition of the Plate Glass market is slightly improved, as prices are somewhat firmer. Quotations are as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Criticisms on the New Cut-Nail Card.

WE HAVE RECENTLY received several letters in which criticisms are expressed on the card now in use for Cut Nails and some of its inequalities are pointed out. One of these letters is from a representative Hardware merchant in the West, whose inquiry we submit to our readers:

It seems to me that the card adopted is altogether impracticable. The objection to the old Nail card has been, that the average of advance had to be ascertained before prices could be quoted—the higher the average the lower the rate—showing that the advances were too high. Now, to equalize this, the advance should have been reduced, and it seems to me that the National card (or list) adopted January 31, 1893, was about right—at any event, it was a move in the right direction. This last card, February 15 and 21, increases the defects of the old card: to show more clearly, take 6d Common Nails, which are medium price, and I think more of them sold than any other number.

Advance on 6d Common Cut Nails:

Old card.	List Jan. 31.	List Feb. 15.
$0 40	$0.20	$0 75

Now, if in practice 40 cents advance was too high, how about an advance of 75 cents? Would like to hear what others have to say about this.

Another correspondent favors us with the results of his figuring and arrives at some interesting results by comparing the average cost of different assortments of Cut Nails; also the cost of fancy Nails on the old and new cards, as follows:

Having a little time one day, between calls, I did a little figuring on the Wire Nail card, as shown below, to see what advantages would be gained by ordering different assortments of Cut Nails by this card. While the assortment of Nails given would not suit my trade, it answered to arrive at results. As the new card was adopted to do away with figuring on averages—that is, of decreasing the base price in proportion to the advance of the average, I figured on a $1.25 base price irrespective of the high or low average of the assortment. The price of the 250 kegs of Nails was $466.50, as here shown:

No.			Extra.		
8,	Fine	10 kegs	$1.60	=	$16.00
4,	Flat	5 "	.90	=	4.50
4,	Common	5 "	.90	=	4.50
5,	"	5 "	.90	=	4.50
6,	"	25 "	.75	=	18.75
8,	"	60 "	.60	=	36.00
10,	"	70 "	.50	=	35.00
12,	"	30 "	.45	=	13.50
20,	"	10 "	.35	=	3.50
40,	"	5 "	.25	=	1.25
60,	"	5 "	.00	=	0.00
8,	Finishing	10 "	.90	=	9.00
10,	"	10 "	.75	=	7.50
		250 "			$154.00
250 Kegs at $1.25				=	$312.50
					$466.50

I found that the average cost per keg of the 250 kegs, at $466.50 for the lot, was $1.86⅔. Then from curiosity I divided the sum of extras, $154, by the number of kegs to find the average, which proved to be 61 $\frac{8}{10}$ cents.

It is interesting to note that the same assortment of Nails on the old Cut-Nail card was a 35-cent average. Now, I thought if I should sell out my Common Nails and have to replace them to enable me to get rid of the fancy Nails, I would see how much they would cost me all around, and if I would be losing money if I sold my first lot of Common Nails proportionately to their cost, with possibility of my next lot costing me more, so I took out the 3 Fines, 4 Flat, 5 Common and 8 and 10 Finishing. This left me 210 kegs, costing on a $1.25 base, $375.

		Kegs.	Extra.	
4,	Common	5	$0.90	$4.50
6,	"	25	.75	18.75
8,	"	60	.60	36.00
10,	"	70	.50	35.00
12,	"	30	.45	13.50
20,	"	10	.35	3.50
40,	"	5	.25	1.25
60,	"	5	.00	0.00
		210		$112.50
$2.10 @ $1.25 base				262.50
				$375.00

I found that this assortment was about a 53-cent average, and so the order would be accepted, as it averaged 50 cents above the base price. I also found this assortment brought the average cost per keg to $1.78⅛, against $1.86⅔ as before, so that I could sell them at the same price as I did my first lot and make a larger profit. I came to the conclusion that there were great possibilities in this new card. Of course the last lot of 210 kegs was not up to the usual carload quantity of 250 kegs, but the quantity could be increased by the addition of Common Nails without materially increasing the average price. I also found that while some sizes of the Common Nails cost more on the new than on the old card, some sizes of fancy Nails cost less, as follows:

	Old card.	New card.
8, Fine	$2.90	$2.85
8, Finishing	2.40	2.15
10, "	2.25	2.00

This result was reached by taking $1.40 as a base price on the old card and $1.25 base price on the new card.

Trade Notes.

THE GLOBE VENTILATOR COMPANY, Troy, N. Y., have made a recent shipment to the Johnson Steel Rail Company, Johnstown, Pa., of six 60-inch Globe Ventilators, and to the Chicago, Rock Island & Pacific Railway of three 72-inch Ventilators.

THE ECONOMY HEATING DEFLECTING COMPANY of Columbus, Ohio, are distributing an oblong pamphlet of 16 pages devoted almost exclusively to testimonial letters from those who have used their Economy Heat Deflecting Damper, which is claimed to effect a large saving in the consumption of fuel. The construction of the device is said to be such that the draft is not obstructed, but rather increased, so that the smoke and gases pass freely through the pipe or chimney. It is also claimed that the damper will not burn out, and that when hard, soft, cannel coal, coke, wood or natural gas is used, the damper produces the same results and can be adjusted to a light or heavy draft chimney.

WE ARE INFORMED by the McDaniel & Harvey Company, Philadelphia, that there is a growing disposition among many leading consumers to use the old fashioned

Charcoal Bloom Galvanized Iron, notwithstanding its slightly greater cost. Sales during the past few weeks and inquiries from new sources are reported very satisfactory. The McDaniel & Harvey Company furnish either Iron or Steel, and have a record on the former extending back into the last century, their plant at Northeast Maryland having been in operation before the Revolution of 1776.

That portion of the plant of Wallace, Banfield & Co., Limited, manufacturers of Tin and Terne Plate, and operating the Irondale Rolling Mill at Irondale, Ohio, which was destroyed by fire in December of last year, has been rebuilt. A new iron building, 90 feet wide x 160 feet long and 22 feet in hight, has been erected, and also an annex 30 x 160 feet in size. This main building contains the tin-plate rolling mill, cold rolls, engines, boilers and shears. The building was erected by Riter & Conley of Pittsburgh, the engines being furnished by Mackintosh, Hemphill & Co., Limited, of that city, while the vertical trimming shears were furnished by the Lloyd Booth Company of Youngstown, Ohio, and the doubling shears by the Leechburg Foundry & Machine Company of Pittsburgh. This concern turn out Tin and Terne Plates, and in addition market a large part of their product in the shape of Black Sheets, of which they have a daily capacity of 30 tons. Their main office is located at the corner of Third avenue and Wood street, Pittsburgh.

The Novelty Stamping Works of Bellaire, Ohio, have been equipped with new machinery and will shortly be started up with a full force of men.

Bramhall, Deane & Co. 264 266 Water street, New York, are just completing an apparatus for sterilizing drinking water, dressings, apparatus, &c., for hospitals and kindred institutions. It consists of an automatic boiler similar in principle to that used in their various cooking apparatus.

Bellaire Stamping Company, Harvey, Ill., are now manufacturing a kitchen ware which they call the Columbian Enameled Steel Ware. It is of a bright gray color, attractive in appearance, and the company claim that the shapes and trimmings are in many cases an improvement on similar goods now on the market. Their factory is thoroughly equipped and in splendid running order and they are turning out a large quantity of this ware daily. The capacity being quite large, they are in a position to take care of all the business offered them and can make prompt shipments.

The Bronson Supply Company have recently increased their staff, enlarged their showrooms and offices at 72 Beekman street, New York, and materially increased their storage accommodations to enable them to meet the demand for a larger stock in New York of the various factories whose output they control. In addition to their factory at Cleveland, Ohio, for the manufacture of their Never-Break ware, the Bronson Supply Company have assumed the entire output and sale of the following manufacturers: Eustis Mfg. Company, Bayonne, N. J., Puritan Ware; M. F. Koenig & Co., Hazleton, Pa., Excelsior Baking and Roasting Pans; Fillgrove Bros. & Co., Ironton, Ohio, Drip Pans, and the products of the Bellaire Stamping Company of Harvey, Ill., for the eastern half of the United States. The line of Puritan Ware includes Cereal, Fruit and Vegetable Cookers, Chafing Dishes, Five o'Clock Tea Kettles, Multiple Cookers, Egg Poachers, Baking Dishes, Coffee Pots, Universal Measures &c.

Fred. J. Meyers Mfg. Company, Covington, Ky., notwithstanding their disastrous fire recently, have already begun to manufacture seasonable goods pending the re-establishment of their permanent plant, having secured temporary facilities. They announce they have a stock of goods at 69 Beekman street, New York, F. J. Mattison, Eastern agent, where customers can be supplied in a small way until they are in better shape to meet demands. They will rebuild at once.

Matthai, Ingram & Co., Baltimore, manufacturers of Tinware and Sheet-Metal goods, were visited by fire, March 14, causing an estimated loss of $75,000. The main buildings and storage warehouses were saved. The boiler and engine are intact, the stamped ware, pieced ware, galvanizing, japanning and tin-plate departments are all right, the main trouble being in the retinning department, where the fire started. They expect to be in operation in two or three days. In sending out a circular to the trade announcing the occurrence they ask the indulgence of customers and friends for the slight delay that may ensue in shipping Sheet Iron Ware and retinned goods. They will commence rebuilding at once, and hope to be in full running order in a short time.

The Millers Falls Company, 93 Reade street, New York, advertise elsewhere their Star Power Hack Saw for cutting metals. A general view of this machine is shown, its usefulness referred to and points of advantage noted.

E. Aspinall, 98-100 Beekman street, New York, is calling attention to the English Enamel for home decorations, for which he is proprietor in this country. It is made in 150 brilliant shades, and is said to have achieved success in Great Britain, France and the Continent. It can be applied to any surface, and is suited for interior or exterior work. It is recommended for household furniture, baskets, tables, bedsteads, cabinets, mantels, walls, iron work, bicycles, or anything which it is desired to paint. He has also a special Enamel for baths, bathtubs, bathrooms, hot-water vessels, &c., and it is claimed it will resist the action of boiling water or dry heat. Both are guaranteed non-poisonous, and will not chip off.

In our advertising columns the Geuder & Paeschke Mfg. Company, Milwaukee, Wis., the well known manufacturers of Tinware, call attention to one of their specialties, the Fairmont Cream Can Gauges. These goods are now regularly used in all the dairy districts in the United States and Canada, and, we understand, are indorsed by dealers and consumers alike for their many points of superiority.

At the Salford Iron Works, Manchester, England, the proprietors, Messrs. Mather & Platt, have lately inaugurated a new system of working time by reducing the hours of labor per week for their employees from 53, as heretofore, to 48, without any reduction in wages. The experiment is made in the hope that the concession will result in greater energy and improved work on the part of the men, and that consequently no loss will ensue. The time is made up by five days of eight and three quarter hours and one day (Saturday) of four and one-quarter. The curtailment of the day has been effected by striking off the before breakfast work, the day's labor beginning at a quarter of eight in the morning. The new arrangement will be in force experimentally for 12 months, and the results at the end of that time will guide the employers as to its permanence or otherwise. Should the reduction of hours not fulfil their expectations the firm hold themselves free to revert to the old system at the end of the period.

The newest type of ocean liner, the "Gigantic," which is about to be built for the White Star Line, at Belfast, Ireland, will have no masts, except a pole for signaling purposes.

A Sunshine Heating Apparatus.

It is said that a certain professor down in New England, which is credited with being a pretty cold part of the country, warms his house during the daytime in clear weather by the heat of the sun alone. A southern exposure of glass and a northern exposure of wall without windows, together with open fires for nights and cloudy days, is the primitive and, as reported, efficient means of securing a comfortable indoor temperature during the winter months. This original plan of house warming is not likely to interfere to any large extent with the trade in heating apparatus, for the curious design of the house, not to speak of the attention to grate fires made necessary by clouds and nightfall, would prevent the general adoption of the system. It is worth while to inquire, however, whether this ingenious householder has not secured by his sunshine apparatus the most agreeable and wholesome warmth that is possible under any conditions; or, to put the question in another way, is not the direct heat from the sun possessed of certain thermal qualities that neither stoves, steam nor hot water will give forth? The small boy who in early spring spreads himself out on a cellar door in the southern angle of the house is as thoroughly contented as a Chinaman in an opium joint. He is no warmer than he would be sitting on the parlor radiator—and the cellar door is a great deal harder than his feather bed—but he feels the sunshine soak into him and warm the very cockles of his heart—an effect that no artificial heat could give.

Properties of Sun Heat.

The boy knows nothing of the chemistry of heat, but nature has taught him without any study on his part that a patch of sunshine on a cellar door is worth more than all the radiator sections in the world so far as solid comfort is concerned. If when the boy grows up he takes a notion to study the little understood subject of heat he will learn that the sun's rays have certain chemical or life-giving properties that he will look for in vain in the heat that is radiated from a stove plate. If he wants proof of what the books tell him let him try to raise a pumpkin vine in a dark room heated by a steam coil, and then after his unsuccessful attempt, if he concludes that light and fresh air are all that are needed, let him repeat the experiment in a ventilated room, heated by the indirect method and brilliantly lighted with lamps or gas. After wasting a good deal of time and work he will come to the belief that he can't fool a pumpkin seed with artificial sunshine, and will give up indoor agriculture, unless he decides to go into the business of raising mushrooms. The New England professor may never have idled away a morning in springtime on the cellar door of his father's house, or wasted any of the springtime of youth in attempting to raise pumpkins in the dark; but in some way or other he must have learned how good a thing the sunshine, is for he has gone to no little bother to have it about him as fully as the clouds permit.

The Sale of Heating Boilers.

A mistake is often made by the manufacturers of heating boilers which injures their trade much more than can be recompensed by any profit realized on the sale. This mistake consists in selling a boiler without restriction to a man who has neither skill nor experience in the erection of steam or hot-water heating appliances, yet who, notwithstanding, purchases the boiler intending to set it himself, and to use it in carrying out some heating contract. Complete or partial failure is the result of the large majority of such attempts. Both the parties to the contract will then be dissatisfied. The unwise owner who has rashly given the contract to the incompetent fitter becomes impatient, then clamorous for the fulfillment of the guarantee. The contractor will not readily admit that failure has resulted from his want of knowledge and skill; but he immediately seeks to impress the owner that the boiler is insufficient. He is near at hand, while the manufacturer is at a distance. He has the ear of the owner, and ten to one will succeed in making the owner believe that the boiler is solely at fault.

An Opportunity.

Now comes along the expert salesman of a rival house. He is quick to perceive his opportunity. Without hesitation he confirms the contractor's statements with reference to the boiler that has been set, and guarantees success if the boiler he now offers for sale be substituted. At the same time he looks over the whole job; shows the contractor how to correct his mistakes; warns him that unless he makes the corrections the job will not work satisfactorily, even with a good boiler—of course, the one already set is pronounced not good—and sells his boiler on the condition that the alterations required be made. When the time arrives for the change to be made this salesman takes good care to drop around again, or have some one do so who knows, to see that mistakes are not repeated, and when the boiler is fired up, presto, the job works. Both the owner and the incompetent fitter are now ready to testify that the boiler thrown out is worthless, and just as ready to swear that the new one is the best boiler made, although with an equally fair trial the rejected one might prove the better of the two.

The Final Result.

The final result, commercially, is that the manufacturer, who sold his boiler to the incompetent fitter without restrictions or conditions as to the way the contract for which the boiler was to be used should be executed, has indirectly sold a, perhaps, inferior boiler for a rival house, and has got at least a locally bad reputation for that of his own make. Very likely he will refuse to have his boiler returned and will sue the party to whom it was sold for payment if, as is also very likely to have been the case, he did not sell it for cash. To recover the payment, even if he obtain a final judgment in his favor, his bother and expense will be more than the boiler is worth, and there are many chances that he will fail to recover at all, because both the owner and the contractor will pull together on the witness stand, and there are always unpleasant contingencies in this sort of litigation. In any event, he is sure to be convinced in the end that it was not good business policy to sell a boiler in this way; and yet, especially if he is endeavoring to introduce a boiler new to the market, the chances are he will repeat the blunder several times before he has burnt his fingers enough to teach him thereafter to keep them out of the fire.

The Recent Boston Fires.

It is rather curious that Boston, wherein the construction of slow-burning buildings, fire-proof buildings and fire insurance problems have been made subjects of investigation, study and debate, to an extent rivaled by perhaps no other city in the world, should, after all its efforts, still prove to be the city supplying the history of conflagration with some of its most startling and voluminous chapters. Edward Atkinson resides in Boston, and is known far and wide by his contributions to the literature of fire prevention and obstruction. Around him are gathered numerous disciples; and it must be admitted that the teachings of this school commend themselves to common sense and apparently accord with scientific principles. Yet, in Boston, fires are not less numerous nor less destructive of life and property in proportion to its size than in other towns not particularly noted for special attention to the subject of fire prevention. Indeed there are few cities that can furnish a record of two such fires as Boston has supplied this winter and spring. It seems from published ac-

counts of fires culled from various authoritative sources that metal studding and lathing supporting walls of ordinary lime and sand mortar affords one of the most resistant obstacles to the rapid and uncontrollable spread of fire known to modern builders. Presumably, as this innovation in its most approved methods of application is of comparatively recent date, the valuable buildings burnt in Boston were not constructed with such interior walls. This kind of partition is finding increasing favor, and the time may come when new buildings in city blocks will not be permitted to be erected without them.

The Atmosphere of Cities.

If city dwellers, and particularly those in the larger manufacturing centers, could witness under the microscope a sample of the impurities contained in the air they breathe, they would probably experience a similar shock to that felt by the teetotaler who once viewed at a church entertainment the stereopticon picture of a magnified drop of water with its various living denizens, and thereafter permanently abjured the internal use of that element to the great scandal of his temperance friends. The city dwellers aforesaid could not, however, take so short a course with the atmosphere, so long as they remain city dwellers. The air of large industrial centers of population, on account of natural causes, can never be anything but injurious to a considerable extent. The only thing that can be done toward mitigating the evil is to endeavor by all means in our power to remove, so far as possible, the causes which contribute most largely to the vitiation. Among these causes stands pre-eminent the volumes of smoke which, to a greater or lesser extent, pollute the atmosphere of all large cities. Even Paris, whose position in this respect has heretofore been very enviable, on account of the large use of wood in that city as fuel, is now, we learn from a French scientific journal, becoming dingier yearly as bituminous coal is more widely employed in factories and other industrial establishments. Although municipal regulations prescribe the use of smoke-preventing methods for these chimneys, it has been found impossible to enforce the law on account of no really efficient system of smoke prevention having yet been devised. The only remedy the journal referred to can for the moment suggest is that a fine should be imposed on all obstinately smoky chimneys, and a premium be awarded for those which do not smoke. By this means it is believed that owners will be driven to devise means for reducing the evil, by the use of clean flues, good fuel, and careful firing. This might bring some slight mitigation, but would be hardly a remedy.

Coal and Fogs.

The avoidance of coal which contains a large amount of sulphur is specially recommended. This substance it is which, almost more than anything else, works harm to the lungs of those breathing city air. The sulphur is given off in the smoke, and descends again in the form of sulphuric acid, mingled with rain and fogs, with the result, as has been strongly put, of absolutely "vitriolizing" all coal-consuming centers, with their surroundings. The "pea-soup fogs" of London, for instance, where soft coal if universally used, are unquestionably due to this cause. Hundreds of tons of unconsumed matter are daily thrown into the atmosphere with the smoke of the city. In the British capital, indeed, this nuisance has risen to a pitch happily inconceivable in our more favored cities. The harm to life and health wrought there by the fog fiend every winter has become so alarming that scientists are at their wits' end to devise some method of mitigating the evil. Meanwhile, the use of hard coal is being strongly advocated in some quarters as one mode of lessening the plague of fog.

Impurities in Dust.

The impurities discharged into the air we breathe by smoke are not, however, the only ones which penetrate the atmosphere of cities. The dust caused by traffic, street sweeping, and the general motion which is always going on, pours into the air a mass of deleterious organic matter, which is inhaled by those passing along the streets, and is blown into the houses. At the Observatory of Montsouris, in Paris, experiments of a most interesting nature have recently been made with the air and dust of that city. A sample of the latter, for example, weighing $\frac{1}{15}$ grain, taken from the third story of a house in one of the principal Paris streets, on being collected and analyzed, was found to contain lime, silica, plaster, coal, pulverized stone of various kinds, hairs and fibers, and vegetable debris of all descriptions, together with some 3,000,000 bacteria. Now, it has been found that a gramme, or 15½ grains, of ordinary Paris street dust contains about 130,000 bacteria.

Germs in House Dust.

The experiment therefore goes to prove that there are infinitely more of these germs in-doors than out of doors. This is explained by the fact that the dust which penetrates the interior of a building is generally divested of the heavy mineral atoms which form part of road dust and make it so much weightier. Consequently the cloud of dust which blows in one's face on a windy day is less harmful to breathe than the more subtle substance put in motion in our rooms by the broom or duster. A distinguished foreign authority on domestic hygiene has argued vigorously against the use of the broom or feather brush in-doors, as most unsanitary, in displacing dust charged with dangerous germs. He recommends the use of one of the modern carpet sweepers for the floor, and a rag or sponge for cleaning the remainder of the room and the furniture. The germs found in Paris dust by the observatory scientists have been cultivated and developed with the object of investigating their nature prior to devising means for their suppression. This matter is now occupying the time of a number of eminent French scientific experts.

According to the *Street Railway Journal*, the mileage of street railways in the United States at the close of 1892 was 11,665, and the number of cars operated on the same date was 37,399. Of these the electric roads aggregated 5,939 miles with about 13,400 cars, an increase during the year of 1878 miles, or nearly one-half the increase of the mileage of the steam railroads in the same time. The street railways now have several thousands more passenger cars than the steam railroads of the entire country possess.

Insurance Against Laboring Accidents in Germany.

It is about seven years since the German Government instituted a system of compulsory insurance for all those engaged in labor in that country. The report of the Central Insurance Bureau, which regulates the working of the entire system, has been recently presented to the Reichstag. It contains some interesting features in the tabulated results, shown for the first five years of the system, and the deductions drawn therefrom. It appears that at the end of 1890 64 workingmen's associations, organized under the insurance law, and comprising about 5,000,000 of workers, shared in grants and pensions for accidents. Of these perhaps the most important were the associations representing artisans in iron and steel and metal workers generally, which, we find, included 583,000, or 11 per cent. of the whole number of workers. When we come to consider, however, the amounts paid out for accidents, we find that this class absorbed more than 17 per cent. of the total disbursements for accidents in all classes of labor. Further, it is shown that, while the average proportion of individuals in all trades killed or injured while at work during the five years under review was 4.2 in 1000, the proportion in the metal industries was 6 in 1000. These figures clearly prove the fact that workers in metal run far greater risks than those engaged in other industries. To show how regular this proportion has been, we present the following figures for each of the five years under review:

Average of Accidents for 1000 *Individuals Insured.*

Years.	For all industries.	For metal working industries.
1886	2.83	3.64
1887	4.14	5.04
1888	4.35	5.85
1889	4.71	6.71
1890	5.34	7.44

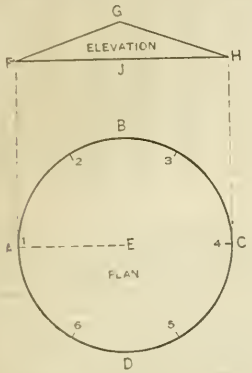
INCREASED NUMBER OF ACCIDENTS.

Another feature which cannot fail to strike the reader of the above figures is the steady increase in the number of accidents, which leads us to ask whether it is possible that one of the results of obligatory insurance is the multiplication of such fatalities, in consequence of less care being taken by the insured workman. Such a result was certainly not contemplated by the advocates of the system, and it gives food for thought as to whether the compulsory insurance of workers has proved a success or not. When we take the figures for German workmen in the metal industries who have survived after accidents, and have been indemnified or pensioned for them, we find the total number for the first year to have been 1521; in the following year 3363; while in 1890 it had attained the largely increased total of 11,853. As is very wisely remarked by *Le Génie Civil* of Paris, in contemplating these figures: "We think that the adoption of every means to prevent accidents should be carried out before arranging to repair the damages caused by them." And this we find is now being done by the insurance associations, for it is stated that an aggregate of $14,000,000 of profit which has accrued during the five years has been placed in the reserve fund, a considerable proportion of which is to be devoted to the organization of special means for the prevention of accidents.

THE TIN SHOP.

Pattern for Steamer Cover.

From H. J. B., *Milwaukee, Wis.*—There may be some of the apprentice or other readers of *The Metal Worker* who would like to see how the pattern for an ordinary steamer cover is obtained. In Fig. 1 let A B C D represent the plan of cover, which is struck from the center E. We will suppose the radius A E to be 6 inches. It is well known that the radius of a circle can be spaced about the circumference six



Pattern for Steam Cover.—Fig. 1.—Plan and Elevation.

times. This gives us a convenient method of obtaining the circumference of the circle when the radius used for obtaining the pattern is near that used for striking the plan, as is the case with a steamer cover. F G H is the elevation of cover, the distance J G being 2 inches. To obtain the pattern of cover from plan and elevation, set the compasses to the slant hight G H,

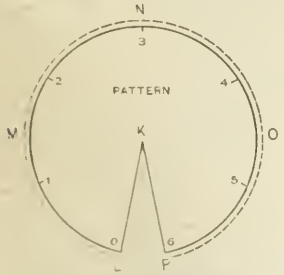


Fig. 2.—The Pattern Shape.

and with any point, as K in Fig. 2, as center, strike the arc L M N O P. Draw the line K L from the center K to end of arc L. With the compasses set to the radius A E of plan, Fig. 1, and starting from L in Fig. 2, space off six of these divisions about the arc L M N O P, as shown by the small figures. From the last point 6 draw a line to the center K, as shown by K P. Such allowances for edges as may be required can be made about the net pattern, as indicated by the dotted lines.

The pattern can be obtained by the use of the square and compasses, thus doing without the drawing of plan and elevation. In Fig. 3 let S R represent the half diameter of cover and S Q the hight. Set the compasses as indicated, with one point at R and the other at Q. With this radius and any point, as K of Fig. 2, as center

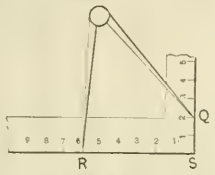

Fig. 3.—Obtaining Radius from Square.

strike the arc L M N O P, and from the center K draw the line K L. With the compasses set to the distance S R, the half diameter of cover, and starting from point L of pattern, space off six of these divisions, as shown. From the last point obtained draw a line to the center, as shown by P K, which completes the net pattern. The allowance for edges to be made as previously described.

Galvanized-Iron Vase.

We are indebted to W. A. Wittbecker, Lansing, Iowa, for a photograph of an interesting piece of sheet-metal work that he has completed. The following brief description is taken from his letter accompanying the photograph:

Galvanized Iron Vase.

I send you a photograph of a lawn vase I built during the dull days of winter, which may be of interest to some of the "boys." The total hight of the vase is 50 inches; diameter of base, 18 inches; diameter of top, 24 inches, with a tube running down inside the stand to drain off any surplus water. The vase is made of No. 26 galvanized iron, principally of scraps such as unfortunately accumulate in every tin shop. I believe that with a little study and application of odd hours that would otherwise be wasted, a great many ornamental and beautiful articles could be made in sheet metal at very small cost. The total weight of this vase is about 25 pounds, which makes it much easier to handle than a cast-iron vase of similar size.

Wash-Boiler Former.

A correspondent recently asked for a method of forming wash boilers, and in reply we received a circular from C. A. Wilbraham, Poquonock, Conn., of a device for the purpose which he manufactures. The article is illustrated in the accompanying cut, and consists of a bed

Wash-Boiler Former.

plate with a suitable peg on the underside to fit into a bench plate. There is also a former block with bands around it and a clamp operated by a screw crank for holding the body of the boiler to be formed against the bands. The desired width of the boiler is obtained by adding or removing the bands, as may be necessary.

It is a great mistake, says *Le Génie Civil*, of Paris, to employ acid for cleaning brass. It becomes dull again in a very short space of time. In order to polish it so that it will retain its luster, the brass should first be rubbed with a mixture of olive oil and fine rotten stone, or tripoli, and then washed with soap and water. When it is desired to "frost" an article of brass in order to give it a decorative appearance, it is well to boil it at first in potash, rinse it with fresh water, and then plunge it into nitric acid, after which it should be rinsed again with water, and finally dried in warm sawdust, and while the metal is still warm it should receive a coating of varnish.

Fourteen Austrian iron workers, bound to Joliet, Ill., were returned to Europe from this port last week, under the Contract Labor law.

The seven trunk-line railroads from the West which terminate at this port have contracted for over 1,000,000 bushels of grain, to be transferred by rail from Buffalo to New York on the opening of navigation, at 6 cents for wheat, 5½ cents for corn and 4 cents for oats. An effort by these railroads to avoid the severe cutting practiced last year appears to be in favor of the canals.

House Warming.—VII.

RELATIVE SOURCES OF HEAT.

Having now considered in an elementary manner the three sources of loss or diffusion of heat, it may be well to ascertain by comparison their relative effect in connection with our subject of house warming. As by conduction the transmission of heat is confined to solid and liquid bodies, it is impossible for it to have any direct influence upon the temperature of the atmosphere, although indirectly it is an important element in the calculation. For instance, if the material of which the heated body is composed were of so low a degree of conductivity as to transmit the heat through its thickness less rapidly than it is given off by the surface, it is manifest that the external surface must become cooled down below the temperature of the other side exposed to the source of heat, in proportion to the comparative rapidity of the conduction and surface loss. As an extreme case let us consider, by way of illustration, a plate, 1 foot square by 1 inch thick, of gray blotting paper, exposed on one side to a constant temperature of 100°, and the other side to the atmosphere at 60°, the difference, therefore, being 40°. By Table XII we find the conductivity to be 0.274 heat unit per square foot per hour for each degree of difference in temperature of the two sides; or, $0.274 \times 40 = 10.960$ heat units as the total conducted heat. Now, supposing the external surface to have been protected from loss of heat until the entire thickness had become uniformly heated to 100°, and the protection then removed. There would immediately occur a certain rate of loss by radiation and contact of air. Referring to Table XIII, we find the loss from radiation for paper to be 0 7706; and by Table XIV, by contact of air for any material, 0.5945 heat unit. Then, $0.7706 + 0.5945 = 1\ 3651 \times 40° = 54.604$ as the loss by the surface, against 10.96 transmitted by conduction under similar conditions, or almost exactly five times as much. In this instance it is clear that the loss or diffusion of heat must be calculated from the conductivity alone.

Now let us consider clean cast iron under the same conditions. Table XII gives the conductivity as 233 heat units for each degree, and $233 \times 40 = 9320$ total heat units per hour. By Table XIII the radiating power is 0.648; and Table XIV, contact of air, 0 5945. Then $(0.648 + 0.5945) \times 40° = 49\ 7$ heat units per hour as the total loss or diffusion by the external surface, against 9320 heat units conducted through the 1 inch thickness of metal to supply such loss. In this case there can manifestly be no reduction in temperature of the external surface. From this we see that it is always necessary to consider the conductivity of the material of which the heated body is composed, although so long as it is so greatly in excess of the surface loss it need not enter specifically into our calculations.

The comparison between the loss or diffusion by radiation and that by contact of air is important, in order to enable us to compare their relative efficiencies, as in some forms of heating apparatus there will be a predominance of one, and in others, the other source of diffusion. For instance, a grate fire heats by radiation only, a hot-air furnace by contact of air only, and a stove by both. It may also be important to know the relative amounts of diffusion from the stove, due to radiation and contact. By the tables (XIII and XIV) we find for cast iron a loss of 0 648 by radiation, and 0 5945 by contact of air, a difference of 0.0535, or but 8¼ per cent. less for the latter. For this material, then, they may be considered as of substantially the same efficiency. Any other material will, of course, give a different ratio. We may compare the two quantities for brick, plaster, &c., as they are important in being the materials of house construction. By Table XII we find the conductivity sufficiently in excess of surface loss that it need not be considered. Table XIII gives the radiation as 0.7358; and if we assume the case of a wall 10 feet high, we find, by Table XIV, that the loss by contact of air will average 0 4347. Here, then, we find considerable difference, the radiation being $0\ 7538 - 0.4347 = 0.3191$ units, or over 73 per cent. greater than the loss by contact. These two comparisons may be borne in mind, as they will be useful in connection with our later calculations.

LOSS FROM OUTSIDE WALLS.

In the foregoing consideration of this portion of our subject, reference has been made to "loss of heat" from the three sources, principally as a means of heating the air of rooms. It is clear, however, that the same data will apply equally to the losses by walls, windows and other exposed surfaces which operate against the maintenance of the desired atmospheric temperature. In the latter application—except in extreme cases—the simple rules and tables given will be sufficiently correct for all practical purposes. Where the difference in temperatures, however, exceeds from 20° to 30°—as in case of 70° in the room and zero or below outside, or between the heat of a grate fire or stove and that of air in the room—there are certain allowances necessary in order to obtain even approximately accurate results. But this is not the only cause for which corrections must be made.

It is shown as the result of experiments by Dulong, and also by Péclet, that the degree of temperature of the heated body, as well as the difference between it and the absorbent, has a very important effect on the rapidity of transmission of radiant heat, and that while at ordinary temperatures the loss may be considered as that due to the difference only, yet at high temperatures it greatly exceeds the amount by previous calculations, and by a constantly increasing ratio. At very high temperatures the ratio of increase of loss amounts to many times the quantities given for ordinary cases, and Péclet and Dulong have formulated rules by which the calculated ratios agree very closely with the results of their experiments. These rules, however, are too complicated for use in this connection, or for ordinary application, and for this reason Box has calculated, from the experiments and formulæ of Dulong, the following tables of the ratios of the increased loss at given temperatures, and differences between that of the heated and recipient bodies. In Tables XVIII, XIX and XX these ratios are given in the order named for radiant heat and contact of air, and for both at very high temperatures.

Table XVIII.—Ratio of Loss for Radiant Heat.

Difference of temperature between bodies Fahr.	Temperatures of the body receiving the radiant heat.

The use of Table XVIII is very simple. Knowing the temperature of the heated body and that of the absorbent or receiving body, we ascertain the difference between the two. Find the temperature nearest to this difference in left-hand column of table, and in the line of temperatures of recipient body, in top line, the one nearest that of the desired figure.

For instance, we wish to find the ratio for a difference of 200° and a recipient of 100°. By vertical column we find 198° to be the nearest to 200°, and in the horizontal line 104° is the nearest to 100. The ratio for these two numbers is 2 04, and as both numbers are very close to the actual temperatures, the slight variation may be disregarded. The ratio found is to be used by multiplying the decimal found in Table XIII for radiant heat, corresponding to the kind of surface of the radiant body in question. We have then only to multiply by the number of square feet of surface and the difference in temperature between the two bodies to ascertain the total loss from radiation in one hour.

For example, we may use the above temperatures, and assume both the surfaces to be black sheet iron, which we find by Table XIII to lose 0.5662 heat unit per square foot per hour for each degree of difference in the two temperatures. Then $0.5662 \times$ ratio number, $2.04 = 1.156$; and the difference of temperatures, as above, being 200°, we have $1.156 \times 200 = 231.2$ heat units per square foot per hour; and if there be, say, 100 square feet of surface, the total loss per hour will be 23,120 heat units. While the above applies to radiant heat only, it is known from the experiments of Dulong that the loss by contact of air increases more rapidly at high temperatures than would be due to merely the difference between the air and heated body, although not nearly to the extent as we have seen to be the case with radiant heat. This difference, as will be seen by reference to Table XX, is very marked at excessively high temperatures, but the increased ratio of loss by contact, even at temperatures within the range of our subject, is sufficiently large to make it an important element in our calculations.

In Table XIX these ratios are given for a range of temperatures sufficient for ordi-

nary purposes, while in Table XX are given those relating to extreme cases. The use of the ratios found in these tables is precisely the same as that described for ratios of Table XVIII.

Table XIX.—Ratios of Loss for Convection.

Difference in temperature of heated body and the air in contact.	Multiplier or ratio of heat.	Difference in temperature of heated body and the air in contact.	Multiplier or ratio of heat.

2580—White. ...	60	2520	4904 00	2.985

Box expresses some doubt as to the applicability of these formulæ of Dulong and Péclet to extremely high temperatures, and cites the ratio thus found (Table XX) for a white heat of 2580°, which is given as 4604, in confirmation. He suggests, however, in support of their correctness, that the great rapidity with which a white hot mass cools down to orange and red may fully agree with the ratio given.

If we suppose, for instance, a mass of white-hot iron, which at atmospheric temperature will measure 1 cubic foot (weighing say 480 pounds), it will contain at 2580° a certain number of heat units, calculated as follows: By Table IX we find the specific heat of wrought iron to be 0.11379, and for 480 pounds there will be 0 11379 × 480 = 54 6182 heat units for each degree of temperature. The difference in temperature between the iron and air at 60° is 2520°, and 54 6182 × 2520° = 137,638 heat units, total. Now we have seen that unless there be contact with some solid or liquid body there is no loss of heat by conduction, and that radiation and contact of air are the only sources of loss. Also, that such loss is directly proportionate to the amount of surface of the heated body. Let us say, then, that our cubic foot of iron is in the form of a plate 1 inch thick, 3 feet wide, and 4 feet long. The amount of surface, then, will be the two sides containing (4 × 3) × 2 = 24 square feet, and the edges 1 inch wide by (4 + 3) × 2 = 14 feet long, or 1⅓ square feet, making the total surface, say, 25 square feet. There is not much question but that such a plate—if placed vertically on end upon supports which permitted a free circulation of air—would cool down to a cherry red heat in say 6 minutes, or one-tenth of an hour. Assuming this to be true, we may easily calculate the ratio by which the loss would exceed that due to the calculation by the simple rules we have considered.

First, to ascertain the loss in one tenth hour from 2580° to cherry-red or 1500°. The difference is 1080°, which, multiplied by the loss per degree, as above found—say 54.62 heat units, = 58,989, or multiplied by 10 = 589,890 as the rate of loss per hour. Now, to find the calculated loss by the simple rules, we have for radiation (Table XIII), by sheet iron, a loss of 0.5662 · and by Table XIV, from contact of air, 0.4780 for 4 feet high, vertical plane. Adding these two quantities and multiplying by the number of square feet of surface, and by the average difference between the temperatures of the air and the iron, we have (0 5662 + 0.4780) × 25 square ft $\times \left[\left(\frac{2680^\circ + 1500^\circ}{2} \times 2090^\circ\right) - 60^\circ\right] =$ 52,993 heat units as the total loss per hour.

As we have calculated the actual loss to be 589,890 heat units per hour, it is as 11 3 to 1, which is the ratio of loss from the combined causes, due to the high temperature. By Table XX, however, we find that the calculated ratio for contact of air is but 2.985, as against 4604 for radiation, and therefore to ascertain the individual ratio for the latter we must eliminate the quantity of loss by contact of air—assuming that the ratio 2.985 is correct. The simplest method of doing this will be to multiply the actual loss—589,890—by 0.4780 and divide by 0.5662, and multiply this amount by the ratio. We have then $\frac{589,890 \times 0.4780}{0.5662} \times 2.985 =$ 148,551 total heat units lost by contact of air. And 589,890 — 148,551 = 441,339 heat units lost by radiation. As we have found the uncorrected loss by contact of air to be 24 258 heat units, we deduct that amount from the uncorrected total, and the difference will be the amount due to radiation, from which we may calculate the ratio. Then 52,993 — 24,258 = 28,765 heat units per hour, by radiation. And 441,339 ÷ 28,765 = 15.343 as the mean ratio of loss at the range of temperatures between 2680° and 1500°. As the average of this range, as above, is 2090°, and the table gives a ratio of 80 67 for 1500°, it would appear from the above calculation that there is a good reason for Mr. Box's doubts as to the rule holding good for such extreme temperatures. For such as are necessary to consider, strictly within the range of our subject, however, the ratios as given in the tables may be safely used, they being accepted as correct in ordinary practice.

(To be continued.)

August Miller, Burlington, Iowa, has been granted a patent on a new form of hot air pipe, the invention relating to double pipes to use in partitions. A special feature is that each section of the hollow pipe is so made as to be adapted easily to the next one, while at the same time the walls are so braced as to hold their shape and yet not interfere with the transmission of cold air between them.

A Polish statistician has recently published some interesting data in relation to the working days of various nations. The days in the year on which the different populations labor are given as follows: Interior Russia, 267; Canada, 278; Scotland, 275; England, 278; Portugal, 283; Russian Poland, 288; Spain, 290; Austria and the Russian Baltic Provinces, 295; Italy, 298; Bavaria, Belgium, Brazil and Luxembourg, 300; Saxony, France, Finland, Wurtemberg, Switzerland, Denmark and Norway, 302; Sweden, 304; Prussia and Ireland, 305; United States, 306; Holland, 308, and Hungary, 312.

Molding Sand.

A valuable tract of molding sand, writes a correspondent, has been discovered near Buffalo, N. Y., which, it is estimated, contains at least half a million cubic yards. Heretofore the fine sand beds in the vicinity of Albany, N. Y., have had almost a monopoly in supplying molding sand. Iron founders pay from $1.25 to $6 per cubic yard for sand in different grades, the rule being that the farther West the sand goes the higher the price. In Buffalo alone it is estimated that in the neighborhood of 50,000 cubic yards are used every year, the greater part of which comes from Albany. Buffalo has a fine location for distributing her newly-discovered sand, and bids fair to become a formidable rival of Albany in this industry. Manufacturers of car wheels, cast-iron pipes, structural iron, machinery, stoves, castings, and numerous other kinds of iron work, are all large consumers of this sand.

The important discovery was made some months ago, and arrangements are being made for working the beds. There are said to be all the grades of molding sand, which have a firm quality, adhesive and elastic, and must not contain over a certain percentage of lime. Lime burns the iron, and the less lime there is the better the sand. The sand is also said to contain considerable iron, a point in its favor. Professor Vandenburgh has made an analysis of it and found only 1½ per cent. of lime. The deposit lies between Buffalo and Tonawanda, not far from the New York Central & Hudson River Railroad. A stock company will be formed and a plant established. The projectors of the enterprise expect to open the tract in May and begin moving sand at once. They think it will be a benefit to Buffalo's industries and will bring new manufactories to that city. It is estimated that the deposit will last at least ten years.

A New Way to Treat Sewage.

One of the most recent plans, says an exchange, for treating sewage in a manner to conserve the public health is that described by Dr. Burghart before one of the English engineering societies. This is an electrical process, the active agent, iron, being derived from iron plates placed in cells, through which the sewage constantly flows; one set of cells is positive and the other negative. Only the positive plate is acted upon and dissolved upon its surface, hydrated ferrous oxide being produced by the action of the nascent oxygen—liberated by the decomposition of water at this pole—acting upon the metallic iron. This hydrated ferrous oxide, which is a solution, then acts upon the organic matter, becoming, first, hydrated ferric acid by absorption of oxygen from the air, giving up this oxygen again to the organic matter and becoming the lower oxide—the operation being repeated for a considerable time until the carbonaceous matters which are oxidizable have been oxidized, when no further reduction of the ferric hydrate can take place, and it remains insoluble and suspended in the effluent as a yellowish precipitate. In order to cause the plates to wear off or dissolve equally the poles are reversed on alternate days, a plate being positive on one day and negative on another day.

What is said to be the heaviest phosphor-bronze casting on record has recently been turned out by John Abbott & Co., Gateshead, England. It is a stern post, weighing 13 tons, for the Elswick Works of Armstrong, Mitchell & Co., the great English constructors.

WORLD'S FAIR NOTES.

English Schemes for Traveling Expenses.

English mechanics have evolved a novel scheme for visiting the fair. In many of the big factories of the Midland districts of England the employees are organizing lotteries for holiday trips to Chicago. The experiment was tried with success during the Paris Exhibition, but the distance being shorter clubs did not procure such wholesale reductions in rates as they will this summer.

Twenty or thirty operatives pay 1 shilling per week to a treasurer, who is chosen by ballot. These payments have been kept up during the winter and now amount to a considerable sum, to which has been added the forfeited subscriptions of those members who have been delinquent. About April 1, when a given sum has been attained, the club will open negotiations with some tourists' agency. The agent is told how much money is on hand, and is asked for estimates as to the number of persons who can be transported and cared for during the fair for the given amount. He may decide that the money in hand will suffice for six persons from Birmingham to the World's Fair, including, of course, hotel accommodations while in Chicago. Then the six men who are to make the journey are selected by drawings. Those who hold the lucky numbers are given certificates good for the trip, while those unlucky in drawing blanks must stay at home. The holder of such a certificate may dispose of it as he desires, as it is transferable. A great many have gone into such schemes as an investment and will sell their certificates if they draw prizes at an advance. Lottery schemes of all kinds take well in England, and it is reported that the World's Fair lottery projects are patronized to a great extent.

Of course this method does not mean travel *via* fast steamers and express trains. But a general good time is promised, and comfort and convenience so far as is possible has been guaranteed. More attention is paid to cheap excursions for workingmen in England than in any other country. There are many firms there who give very low rates to such parties and make money. These firms keep many agents abroad arranging special rates at hotels and boarding houses for excursionists. Their representatives have been in Chicago during the past month securing quarters in the second-class hotels for their patrons, and the indications are that during the summer many such visitors will enjoy the sights at Jackson Park.

Hotel Accommodations.

A recent count by a local journal disclosed the fact that up to that time work had begun on no less than 279 structures, containing about 34,000 rooms, in the World's Fair district, comprising the territory south of Fortieth street, north of Seventy fifth street, and east from the boundaries of the south parks and the Washington Park Club. In securing the totals no attention has been paid to any hotel projects which thus far exist solely on paper. Some of the latter will doubtless be built, but they are too uncertain to be considered in cold figures and tables. Nor have any hotels been included which will cater directly to World's Fair trade, but which were constructed prior to six months ago. It is immaterial for what purpose the buildings will be used after the fair. Some will be torn down and others given over to residences and flats. Just at present they are all hotels, and must be counted in when Chicago's capacity to entertain next summer's visitors is being computed. Private residences, where one or more rooms will be rented, and hotels built before the World's Fair period will increase the number of available rooms in the exposition district to nearly if not quite 50,000. Hotel men state that visitors will average two to a room. If this be correct, 100,000 people can walk to the exposition from the quarters provided for them and walk back in the evening. The total capacity of the hotels in the business district of Chicago has been more than duplicated in about six months in the immediate vicinity of the fair. It is claimed by the Chicago people that no World's Fair ever before made such ample preparation for the accommodation of visitors.

Sweden at the Fair.

Arthur Leffler, the chief commissioner of Sweden to the World's Columbian Exhibition at Chicago, and Axel Welin, assistant secretary to the Royal Swedish Commission for the Chicago fair, have arrived in this country. Being interviewed, they said that the Swedish exhibit would be one of the finest at the fair. Mr. Leffler said the Government had appropriated 350,000 crowns, or about $100,000, for the exhibit to be sent to Chicago, and that that amount, in proportion to the population of other countries, was the largest appropriation made by any European country. "The Swedish Government is taking more than ordinary interest in the fair," said Mr. Leffler, "and it has done something in the way of appropriating that no other country has thought of. In addition to the 350,000 crowns for the exhibit, the kingdom has appropriated 50,000 crowns to be used in sending the mechanical engineers of the country to the fair. Sweden regards the exposition as a great educational institution, and it wants its mechanical engineers to get the benefits of a visit to Chicago, and the 50,000 crowns is for the purpose of assisting them to get there. The exhibit left Sweden on March 2, and the articles will be in their place in our building at the fair grounds by April 1. The most prominent articles of the exhibit will be of iron and steel. The other articles will be in clay, cement, wood pulp, porcelain and wick. Our art exhibit will be comparatively small, but it will prove to be a surprise to the judges in the art department. There are only about 75 exhibitors in this department, but some of the most celebrated artists of Europe have contributed, and among the 200 works in oil, pastel and water colors some superior work will be seen. Two of our great sculptors, Kasselberg and Borjesson, have contributed some of their skill to the exhibit."

Europe at the Exposition.

Theodore Stanton, resident commissioner of the fair in France, has collected reports from the various European commissioners as to the part that their respective countries will take at the coming exposition. From these reports, Mr. Stanton says, "One is readily convinced that the artists, inventors, manufacturers and farmers of the Old World will carry off many and signal honors at Chicago." Germany, France, Russia and Denmark in particular will make a great showing at the fair, while Sir Henry T. Wood writes that while machinery will not be so good as in previous British sections, "it is expected that Great Britain will quite maintain the position she has always occupied at the international exhibitions," despite the fact of "a certain disinclination on the part of her manufacturers to take part in any more exhibitions." The collection of pictures will be "extremely good;" scarcely any of the best known artists will be unrepresented, and in view of the great exhibit Germany is preparing in manufactures, it is fair to presume that Great Britain, however averse some of her manufacturers may be to incur the expense, will be sufficiently awake to her commercial and manufacturing interests to make every effort to hold her own in Machinery Hall with a rival that has been pressing her close of late years. The markets of the world are open to the winners of the Columbian awards, a fact that every manufacturer fully appreciates, whether in Europe or in America. Supremacy in manufacturing, like supremacy in politics, in art, in literature, in everything in fact in life, is never conferred once for all. The prize medaliats of Paris in 1889 in commercial and manufactured articles must add to their record "Columbian Exposition, 1893," or make way for their latest and more enterprising competitors. Championship in every article of manufacture or art, like the championship in pugilism, can be held only on the ground of being able to hold the field against all comers.

There is no reason to fear, therefore, that in all the infinite variety of articles that enter into commerce between the different nations of the world, or in the higher realm of art and artistic manufacture, the progressive nations of the world will not be adequately represented. The eager demands for space in the various departments of the exposition long ago gave evidence of this interest in the fair, and if any further testimony were needed it is supplied by the reports of the commissioners of the respective countries of Europe.

The Canadian Pacific Exhibit.

Five of the finest cars manufactured by the Canadian Pacific Railroad were hauled into Jackson Park on the 15th and installed in the Transportation Building as the exhibit of that railway. Every car is of mahogany. The wood for the exterior comes from the foresta of Honduras and is polished to the smoothness of plate glass. The interior is of light mahogany known as prima vera. The engine which ran at the head of the train did not have steam up, as the exhibit was hauled by another engine. The train is 400 feet long. The entire display was manufactured at the Montreal shops.

General Passenger Agent McNicoll witnessed the installation of the cars and said:

"The train is not purely for exposition purposes. It is a perfect representation of the standard cars in service on the Canadian Pacific. All of our latest passenger coaches are of mahogany, and the engine is a type of half a dozen which are now employed on the line. This particular train will be run between Chicago and Montreal when the exposition closes."

The coaches will be landed on the track alongside the passenger train of the London & Northwestern of England. It was the intention of the Canadian Pacific to institute a comparison between the railroad accommodations on this side of the water and those furnished in Great Britain.

The baggage car is of the standard type, and its length is 63 feet 8 inches. It weighs 59,000 pounds, and has plate glass wherever glass is used. Its exterior finish is mahogany, the same as the coaches.

Next to it is a second-class car. It looks, however, as fine as the others. It is intended for sleeping purposes as well as being a day coach. The furnishings are of leather and the second-class passengers who ride in it—the capacity is 64—will be furnished with a smoking compartment as well as lavatory and other modern accessories.

Next to the second-class is a first-class coach. When it was run over the scale at Montreal, it weighed 32½ tons and has a capacity for 56 passengers. Here begins the work of E. Colona, the architect of

the company. He has designed the interior of the coach after the early Italian Renaissance and the furnishings are of copper red plush with white mahogany and old oak, upholstered with olive corduroy. To break the tunnel-like appearance of the interior of the average coach this one has two arches, giving an air of coziness and comparative seclusion. There is a smoking compartment at one end capable of accommodating six passengers, and at the other another compartment of like size for a sitting room.

In the dining car "Savoy," which is 70 feet 10 inches long, and weighs 42¾ tons, there is a capacity for 30 passengers. The Italian Renaissance prevails in the architecture, and the leather work is of yellow brown with carpets of old India rug pattern.

The last car in the train is a sleeper and bears the title "Satsuma." This is the heaviest coach of the lot and weighs 47 tons. Forty-four people may sleep in it. The plush trimmings are of sage green color. The ceiling is paneled and the interior architecture is of the Spanish Renaissance. The staterooms are *en suite*. Old bronze is the finishing of the metal work.

When the engine which heads the train is fired up it will be capable of hauling ten coaches at the rate of 60 miles an hour. The drivers are 5 feet 9 inches in diameter, and when the machine is loaded up with water and fuel it will weigh 106 tons. It has six drivers.

From one end of the train to the other there are mahogany bronze and brass finishings. It is vestibuled throughout, electrically lighted, steam heated, and has all the latest signal, brake and coupler devices. The cost of the exhibit is estimated at $70,000.

Mines and Mining Far Advanced.

The Mines Building, which will contain iron and steel products, is in the hands of exhibitors. Some of them moved in weeks ago and commenced to build the pavilions in which their metals will be shown, but the big crowd came last week. Seventeen States, seven foreign nations and dozens of individual exhibitors have laborers on the floor and in the gallery getting their shows ready. Chief Skiff says: "Every exhibit for this building will be in place before the opening of the fair. Most of the exhibitors have assured me that they will have all their work done by the middle of April—two weeks in advance of the opening. Some of them may be a little later. They may not get their displays arranged until a few days before the opening, but most of the States, nations and individual exhibitors will be ready before the required time. During the last few weeks we have received many requests for space in the Mines Building—in fact, as many as came in during the preceding three months. Many of them were very desirable displays, perhaps as good as we will have, but the space had all been assigned, every inch of it, and we could not take the late comers in."

Five of the greatest colleges of Germany have united in sending a collection from their mineral museums. "It is a superb exhibit," Mr. Skiff remarked, "perhaps the finest that has yet been sent to this country. We reserved 5000 square feet for it in the galleries."

An interesting display for the Mines Building that came last week was the model of a quicksilver mine from New Almaden, Cal. J. P. Randol, superintendent of the mines, made the model some time ago and gave it to the Government Museum. The managers loaned it to Mr. Skiff, to be shown in connection with the exhibit of mercury which is being prepared by Professor Christy of the University of California. By a system of glass panes, arranged carefully, the complete workings of the quicksilver mine are shown in this model.

The American Tin Plate Association have telegraphed Chief Skiff that a good showing would be made. The members have been given the entire south gallery for their exhibit, and are now arranging a division of the labor of putting the plate in attractive array.

An oil well supply company will make an extensive showing of all the machinery used in sinking oil and artesian wells. This will be in a special building near Machinery Hall, although a part of the mines show. The company propose to put their machinery to practical use, and during the fair it will sink a well 4500 feet deep.

West Virginia, Virginia, Utah and Montana have their pavilions well under way. Michigan and Missouri have been working nearly a month. The Ohio board have sent in several carloads of building stone recently to be used in the mineral house of the Buckeye State. All the Colorado displays are in the building.

Promenade on the Roof.

Around the lofty roof of the Manufactures' Building there is to be a promenade for visitors. An unsurpassed view of the grounds and buildings will be afforded and it will probably be the most extensive lofty promenade in the world. Up to the hight where the wall is to be is a distance of 250 feet. But when the sightseers have reached the landing it will not be to find themselves in a narrow coop but on a broad walk, and if the proposed plan is carried out the visitor can travel nearly one mile in rounding the roof of the building. The Hale Elevator company have been awarded the contract for four elevators to run to the roof, and a fee will be charged for the ride.

Feature of the Allis Exhibit.

The E. P. Allis Company of Milwaukee will have in their exhibit at the World's Fair a contract made by James Watt and his partner for the construction of an engine. In 1796, some years after Watt had built his first engine, the Birmingham Flour & Bread Company wanted an engine and the firm of Boulton & Watt, consisting of Matthew Boulton and James Watt, agreed to build it. A contract, as long and formal as a State document, was accordingly drawn up and signed and sealed. The contract, which has been carefully preserved, passed into the hands of Sir John Benjamin, a wealthy mill owner of Birmingham, Eng., who desired it to be exhibited at the World's Fair, and he loaned it to the Allis Company, in whose vaults it now is. It is insured for $2,500.

Items.

The exposition management has made arrangements to supply electric lights at night in all buildings where night work will be required to complete the installation in ample time for the opening May 1. Nothing will be permitted to interfere with the rapid progress of installation work, and the exposition will be opened as advertised, and as the act of Congress requires.

The exhibit from Funchal, Madeira, has arrived, and is being installed in the transportation exhibits department. It consists of a bullock car, yoke and tongue, sledge hack, mountain sled, hammock and two discodels.

Several steam yachts were received last week from the Gas Engine & Power Company of New York for installation in the transportation department. This firm are building two steam launches for the use of the Director General and Lieutenant Baker.

An "anthracite needle," which required two cars for its transportion, reached the Park last week. The only other needle known which compares with it in size is Cleopatra's. The anthracite column came from Pennsylvania as a sample from its hard coal mines.

Russia's exhibit was shipped March 11. That Government has abandoned its intention to erect a characteristic national house as headquarters. The house was entirely framed and set up in St. Petersburg, but the ice blockade in the River Neva prevented its being shipped in time to reach Chicago May 1.

Mr. Ferris is rushing rapidly skyward the construction of his big wheel on the Midway Plaisance. Four towers to be used as false work are completed, and their tops are 235 feet above the ground. The making of foundations has proved an unexpectedly difficult task. The foundation stones, or, rather, concrete, had to be placed 40 feet below the surface of the ground.

Peter Wright & Sons, an English firm, have sent 120 anvils for exhibit in the machinery department.

Laird Bros. of Birkenhead, who are among the leading shipbuilders of Great Britain, have sent to the fair 65 cases of models of ships, including sailers and steamers.

The price of admission to the grounds has been raised to 50 cents to discourage visitors, who have latterly grown so numerous as to impede the work of preparation.

The following table extracted from an article in the *Chautauquan* makes a showing of the world's yearly coal product, not all for the same year, but the nearest approximation obtainable:

	Tons.
Great Britain (1891)	185,479,126
United States (1891)	168,566,669
Germany (1891)	84,347,156
France (1891)	26,199,645
Belgium (1891)	19,865,345
Austria (1889)	8,592,873
Russia (1889)	6,307,800
Sweden (1888)	300,000
Spain (1891)	1,314,147
Italy (1889)	390,320
Total	501,263,081

It may be added that, of the amount given above for the United States, 50,665,431 tons were anthracite mined in Pennsylvania. The total value of the coal output of this country for 1891 is estimated at $191,092,718.

W. H. Preece, the chief electrician of the British general post office, and one of the greatest authorities upon all matters connected with electricity, delivered a deeply interesting inaugural address as president of the Institution of Electrical Engineers of Great Britain, on January 26. He spoke at length upon electric lighting, and predicted a great future for this means of illumination. Some of his statements were remarkable. It would be possible, under certain conditions, he averred, to produce electrical energy at a price equal to coal gas at four cents per 1000 feet. The patent of glow-lamps, or as they are more frequently termed, incandescent lamps, will be "out" in a very short period, and they would then cost about 25 cents as compared with 90 cents, the present price. As regards telephones (the first practical pair of which Mr. Preece himself brought from the United States in 1877), he declared that there was no theoretical reason whatever why we should not converse between London and every capital in Europe, while it was not impossible to speak even across the Atlantic. Heating and cooking apparatus worked by electricity had not, he said, a very favorable outlook.

THE LETTER BOX.

Corroded Lead Tank Lining.

From P. F., *Atlantic Highlands, N.J.*—Last June I lined a tank with 6-pound sheet lead, and now the lead is just like a honeycomb, especially in the bottom. I would like to know if any of the readers of *The Metal Worker* can enlighten me as to the cause of it.

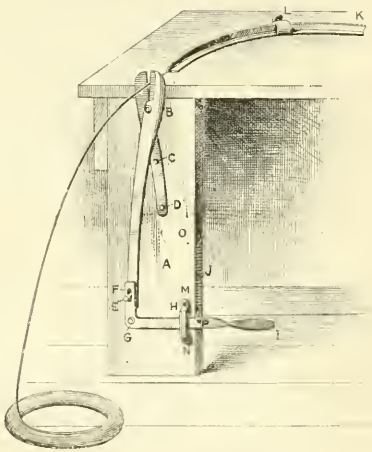
Note.—This is a matter that has been discussed in former issues, and it is an accident, if we may so term it, that sometimes occurs with sheet lead. If any of our readers can throw any further light on the matter, describing the cause and suggesting a remedy, it would be a favor to many.

Better Education of Tinner Apprentices.

From J. D., *St. Louis, Mo.*—I think something should be done to better the standard of the tinner as a mechanic. I find it impossible to get a tinner who understands his business thoroughly. One reason for this is that they do not take an interest in the trade and try to learn while serving as apprentices, but simply work at it for the few dollars a week they get for a year or so and then apply for jobs as tinners. In fact, it seems to be the ambition of the young men in the trade to learn to be helpers, and not to be tinners. If something could be done to change this, I think it would be to the advantage of the tinners, as well as of their employers

From C. N., *La Crosse, Wis.*—It would be wrong to hold each boy individually responsible for lack of interest in his work. It is his surroundings or associates that makes him thus. The average journeyman gives him little or no assistance. Indeed, many would prefer not to have the boy learn, for if he did he would, in many cases, soon know more than his instructor. Under the present apprentice system there are no mechanics made (unless it be in the training schools). The only mechanics we now produce are born. I have many times suggested to enthusiastic union men that they make their organization at the same time a kind of training school, where they could learn and practice drawing and the most approved methods of laying out work. But the real union workers seem to have no time for that, and the better class of mechanics generally do not take much interest in such an institution, as they have little to gain by it. The high wages that incompetent men are asking for their services, and especially the apprentice boys, makes it utterly impossible for an employer or his foreman to spend any of his valuable time in giving them technical instruction. In order to have him earn his wages, he is put and kept at laborious work where he needs little instruction, as helper for a journeyman, getting little or no training, he remains always a helper, and when his three years have been served he is not even a good apprentice, and certainly most of them are incompetent to go as journeymen.

Note.—Complaints of the dearth of good tinners are very general from the west; and our correspondents above quoted are not singular in their experiences in this respect. The cry for better training of apprentices is, indeed, almost universal throughout the country, and this want is to a certain extent being met, in some of the Eastern cities, by the trades schools recently established. A more extended application of the system throughout the cities and towns of the country seems to be the most promising way of raising the standard of the mechanic in all branches of trade, tinning included. As our La Crosse correspondent justly remarks, the fault does not lie altogether with the boys themselves. Their environment, together with lack of opportunity for obtaining competent instruction, takes away all ambition from those who are not "born" mechanics. They have no incentives to push on, and consequently are content to remain helpers.



The Common Sense Wire Cutter.

The Common Sense Wire Cutter.

From J. B Schneider, *Buffalo, N. Y.*—The wire cutter, of which a description is given below, is the best in the world. This may be a broad claim, but nevertheless true, as the writer knows of what he speaks, having had over 20 years' experience in tin and general sheet metal work and as foreman in some of the large tinware factories. This cutter has numerous advantages, the most important feature being fast cutting, the jaws always being open and in such a position as to enable the operator to use both hands for controlling the wire, so he can cut as fast as the foot can work the treadle. A lively boy can cut from 75 to 100 gross of two-quart bucket bails in a day. The machine will cut any size of wire up to No. 6 with ease. If heavier wire is to be cut, larger shears should be used for the machine. It will be seen from an inspection of the engraving that the cutter is a very cheap one to construct, for the reason that in most any tin shop that has been in business a number of years can be found a pair of old stock shears that can be used for the purpose. Any country blacksmith can do the iron work.

To construct the wire cutter. Fasten a piece of 2 x 12 plank, as shown at A, to the end of an ordinary work bench, and secure firmly to the end of bench and floor. Take an old pair of stock shears and cut the blades off, leaving them about 2 inches long. Care must be taken, if they are heated before cutting, that the temper is not injured. The safest way is to cut through the iron while cold, then place in the vice and strike on the steel side with a heavy hammer, thus breaking off the ends. The rough edges can be ground on an emery wheel. Next cut the handles off, leaving the one to be attached to the lever 6 inches longer than the other. Put a $\frac{1}{2}$-inch steel pin in the longer handle, letting it project $1\frac{1}{2}$ inches, as shown at E. The shears B are to be fastened to the plank A by two $\frac{1}{2}$-inch bolts, through holes in handle at C and D. Take a piece of $\frac{1}{2}$ x $1\frac{1}{2}$-inch iron 26 inches long and bend off 6 inches at right angles, as shown. Then cut a slot at F in end $\frac{5}{8}$ x $1\frac{1}{2}$ inches to receive the steel-pin E. Flatten out the other end, as shown at I, for a foot piece. Drill a hole at G for a $\frac{3}{4}$-inch bolt, which secures treadle to plank A. The guard H is made from a piece of $\frac{1}{4}$ x 1-inch iron, bent as shown, and secured to the plank A by means of screws or bolts at M and N. J is a spring made of No. 8 spring wire, and when finished should be 9 inches long and $1\frac{1}{2}$ inches in diameter. It is secured to plank by a screw at O, the other end being turned over so as to pass through the opening in treadle at P. The wire-holder K can be made of $1\frac{1}{2}$ x $1\frac{1}{2}$ angle iron, and bent to the required curve while hot, or it can be made of cast iron. The length of holder K will depend upon length of wire to be cut. The gauge L, which slides on the holder K, is provided with a set screw for securing it in any desired position.

Cleaning Copper for Retinning.

From J. T. H., *Washington, D. C.*—I would like to know the best method of cleaning and retinning copper ware, such as is used in hotels and restaurants. I wish you would submit the inquiry to the readers of *The Metal Worker*. I am doing work of this kind, and sometimes a vessel is exceptionally hard to clean, so that the tin will not readily adhere. There may be some of your readers who know of an acid, or a combination of acids, that may put the roughest of copper ware in condition to be tinned without great labor.

Note.—We would suggest that probably good results may be obtained in cleaning copper ware by the use of hydrochloric, or, as it is commercially known, muriatic acid. We wish our readers who have had experience in this line of work, however, would furnish us with their views.

Aluminum.

From L. A. M., *Mayfield, Ky.*—Please explain the composition of aluminum metal through the columns of *The Metal Worker*.

Answer.—We do not exactly understand our correspondent's inquiry. If he refers to the metal aluminum, we would explain that this is a primary metal and is not a composition of other metals. There are, however, various alloys and mixtures into which aluminum enters, but many of these are trade secrets of the manufacturers. Some ingredients of alloys of aluminum are, we believe, tin, zinc, nickel and lead. We must not omit to mention, however, the aluminum bronzes, in which aluminum plays an important part.

Forming Wash Boilers.

From ON THE ROAD.—In *The Metal Worker* of March 11 "O. J. B." of Troy, Ind., desires to know the quickest way to form up wash boilers. As I have had experience in tin and furnace work in seven different States since I commenced my business 25 years ago, and have made thousands of wash boilers, covers and all, at 20 cents apiece, I will offer a few remarks which may not be without interest to the correspondent named. In the first place, take the band iron which usually comes around Russia iron, or any band iron which is flat and about ⅛ inch thick by 1 inch wide, and cut one piece the length of the circle of the middle of the boiler it is desired to form. It will be the same length as the circle of one end of the bottom of the boiler where it is double seamed. Cut another piece of band iron just as long as the first piece, and flatten the ends down to a thin edge, using either a hammer or file for the purpose. Lay off the body of the boiler and make a mark where the circle is to commence. Raise the upper roller of the former so that the wired edge of the boiler and the short piece of iron will slip between the upper and lower rolls. Then adjust the back roll as nearly as is possible by guesswork, and hold the band of iron on top of the work. Turn the crank and feed the boiler and short iron band into and through the rolls until the short piece has passed through and formed half of the circle on one end. When the short piece of band iron drops off push the body of the boiler through to the mark on it where the middle circle commences. Place the long band iron on top of the wire edge of the boiler at the mark and feed through the same as before. Next, take the short piece and repeat the operation, forming up the last half at the end. "O. J. B." may not obtain a good form on his first boiler, but after he has formed a few he will catch on, so to speak, and find it easy enough. Once get the rollers set right, then do not touch the thumbscrews again. After they are once set, a hundred or more boilers can be set without further adjustment. Oil or grease the top side of the irons so that they will not feed through faster than the boiler. Always break the tin before locking. Run three to five sheets through the roller at a time so as to prevent kinks in the ware when forming up after wiring. Of course, the bottom side of the boiler will not form as exactly as the wire edge, but that does not matter. He can draw the circle down over a stake and true it up, if he wishes, though this is not necessary.

I used to take out six dozen boilers at a time when working in New York City and many times have formed the whole lot in an hour, though I always had to go over them when fitting covers. In order to make covers fit both ways is a knack. Never put a boiler on a stake for the purpose of truening it up. Set it on the floor, take a raising hammer in the left hand, holding it in the inside or outside of the circle, as the case may be, stand over the boiler and with the mallet give it a sharp tap which will shorten or lengthen the circles as may be required. The position of standing over a boiler permits the eye to take in the vital spot which needs a rap of the mallet. This may not interest "O. J. B.," but I tried all ways and could make more boilers this way than any man I ever saw by a different method. I have made 24 boilers and covers in ten hours and my covers fitted either way, and my brother tinners know what that means. Thanks to *The Metal Worker*, however, I answered, ten years ago, a want in the Labor Exchange, and secured a position on the road where I now am, though I still read *The Metal Worker* as eagerly as ever.

Cincinnati Industrial Assembly.

The third of the series of industrial assemblies instituted by the Merchants' and Manufacturers' Association of Cincinnati was held at the Gibson House in that city on the evening of March 14, in the interests of the metal trades.

An informal congress beforehand in the corridor of the hotel served to bring about introductions, and later the march was taken to the dining hall, where the gentlemen took seats.

President Stewart Shillito of the Association sat at the center of the main table, while at his left was President-elect W. T. Perkins of the Manufacturers' Association and Archer Brown at his right.

At the table were President Thomas P. Egan of the J. A. Fay & Egan Company, George M. Verity of American Roofing Company, John Crowther of the Globe Machine Works, John B. Morris of the J. B. Morris Foundry Company, G. M. Morris of the same company, G. C. Witt of the Witt Cornice Company and Harker Mfg. Company, Charles E. Witt of Witt & Brown, while at the other tables were C. W. Magill of W. W. Magill & Sons, D. B. Bayless, F. H. Lawson of F. H. Lawson & Co., W. S. Dickinson of W. S. Dickinson & Co., H. B. Wells and Charles Walter Bell of the Cincinnati Tin & Japan Company W. W. Tyler of Union Axle Company, Myer Ottinger of Isaac Fallers' Sons & Co., E. W. Vanduzen of the Vanduzen & Tifft Company, W. T. Johnston of Crowley & Johnston, J. C. Hobart of Triumph Compound Engine Company, Chris. Kiechler, President of the Kiechler Mfg. Company, Thomas J. Bell of Thos. J. Bell & Co., J. A. Jones of Robert Jones & Co., Col. J. A. Andrews of the Newport Rolling Mills Company, F. H. Osborn of Osborn, Hutchins & Hunt, Ervin Maxwell and Walter H. Maxwell of the Emery and Palace Hotels, F. B. Lotze of A. Lotze's Sons & Co., W. E. Ward, J. R. Stewart of the Bradford Milling Company, W. L. Clements of Clements & Co., H. J. Yosiger of the Eureka Yeast Company, James A. Sebastian of Mitchell, Tranter & Co., L. P. Phipps of the Globe Rolling Mill Company, A. C. Jones of the Jones Bros. Electric Company, Chas. Davis of the Lodge & Davis Machine Tool Company, O. D. Bryant, of the Crane & Breed Manufacturing Company, Chas. F. Thompson of the Lane & Podley Company, James Powell, President of the Wm. Powell Company, G. H. Merkel of Merkel Bros., H. H. Suydam of the Cincinnati Mfg. Company, J. S. Chambers of the Cincinnati Mfg. Company, George M. Clark of the Mitchell-Tranter Company, P. G. March, E. P. Wilson, Earl W. Stimson of the Geo. W. McAlpin Company, Chas. J. Steru of Strauss & Stern.

When the collation had been fully attended to, introductory remarks were made by chairman Shillito, after which he introduced W. T. Perkins, chairman of the Entertainment Committee, who announced that the next assembly would be held at the Hotel Emery, and would be for the wholesale grocery, spice and drug trade.

Among the speakers of the evening were: Thomas P. Egan, president of the J. A. Fay & Egan Company; F. H. Lawson of F. H. Lawson & Co., H. D. Wells of the Cincinnati Tin and Japan Company, Col. J. A. Andrews of the Newport Rolling Mills Company, Charles F. Thompson of Lane & Bodley, Charles Davis of the Lodge & Davis Company, and Joseph Jones of Robert Jones & Co. The topics most prominently touched upon were the Iron, Copper, Brass and Tin interests. Each assembly has shown an increase in numbers and interest over the first.

NEW PUBLICATIONS.

THE CONNECTICUT STEAM USERS' DIRECTORY, 1893. L. F. Middlebrook, Hartford, Conn.

A little work has been compiled with the object of supplying the steam-using public of Connecticut with a convenient book of mutual reference, and the general public with a medium of information to assist in soliciting business, sending circulars, &c. The book supplies the names, location and business of all users of steam in the State, alphabetically arranged under the various cities and towns, as well as a purchaser's guide, containing a list of manufacturers and dealers in other States who supply the necessities of mill owners. The directory should be a useful handbook for those doing business in or with the State of Connecticut.

The paper by Professor N. S. Hele-Shaw on the strength of small chains, an abstract of which was printed in *The Metal Worker*, did not refer to the makers of the American "Triumph" chain, to the extraordinary strength of which he calls attention. We may state, therefore, that the Triumph chain is manufactured by the Bridgeport Chain Company of Bridgeport, Conn., of which George C. Edwards is president and treasurer, and Charles L. Slide, secretary.

The only contracts for power at the great cataract which have been let up to date are with the Niagara Paper Company, who have contracted for 3000 horse power at the rate of $24,000 a year, and the Contract Electric Company of Buffalo, who have contracted for 10,000 horse power, to be delivered at the northern boundary of the city. There have been many other applicants for power, but purchasers seem to be holding back until the first trial is made, in order to see if it is entirely successful.

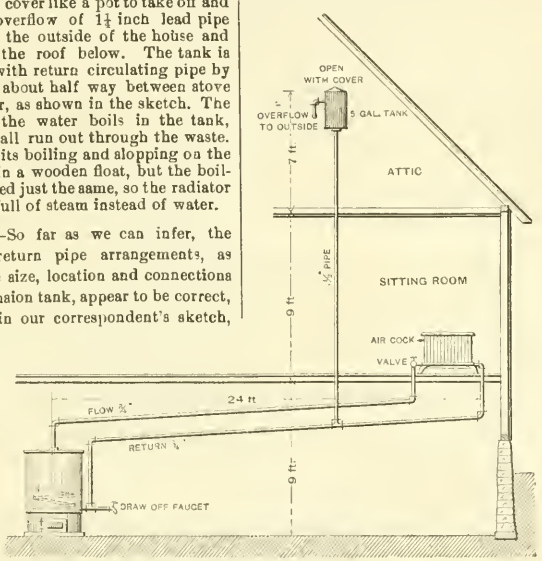
A report from San Francisco says that Claus Spreckles, the sugar operator, proposes to transfer four steamers owned by him and employed on the Australian route and start an opposition line from San Francisco to Panama.

STEAM AND HOT WATER.

Difficulty with Hot-Water Heating.

From R. B., *Massachusetts.*—I have had trouble with a small job of hot-water heating, and would like some information with regard to its working. The stove is an ordinary cylinder stove with sheet iron body and 16 inch fire pot. It is located on the first floor. A coil of ¾ inch iron pipe makes two circuits around the top of the fire pot. The flow and return pipes are ¾ inch, running 24 feet with 8 inch rise on the run to the radiator in second story. A 5-gallon expansion tank of galvanized iron is in the attic with open top and has a common tin cover like a pot to take off and fill. The overflow of 1¼ inch lead pipe leads out to the outside of the house and wastes on the roof below. The tank is connected with return circulating pipe by ¾ inch pipe about half way between stove and radiator, as shown in the sketch. The trouble is the water boils in the tank, making it all run out through the waste. To prevent its boiling and slopping on the floor I put in a wooden float, but the boiling continued just the same, so the radiator would get full of steam instead of water.

Answer.—So far as we can infer, the flow and return pipe arrangements, as well as the size, location and connections to the expansion tank, appear to be correct, as shown in our correspondent's sketch, which we reproduce. The difficulty apparently exists in the coil in the fire pot. In the first place, the coil may absorb more heat than the surface in radiator will give off, and the surplus thus absorbed will convert the water into steam, which in turn will blow the water out of the system. It is not improbable that if the surface in the coil in fire box were reduced the overflowing at expansion tank will be stopped. As our correspondent does not state the quantity of surface in the radiator we can only surmise the cause of the difficulty. If the surface in the radiator is large relatively to the coil in pot, then the overflowing may be due to want of inclination in the fire-pot coil, tending to form a partial trap in which steam may be produced, and by which the water is forced out through pipe to expansion tank. Should this be the case, it will be well to use a 1¼-inch pipe in coil in place of a ¾-inch pipe, and with a regular inclination it will be found to work satisfactorily.



Difficulty with Hot-Water Heating.

Factory Heating by the Blower System.

By Walter B Snow.

VARIETY IN APPLICATIONS.

There is diversity in the manner of application of the blower system as great as the diversity in buildings in which it is applied. Disregarding the higher classes of buildings, such as theaters, churches, halls, office and school buildings, there still remains that extensive class known as factories, as various in their design and construction as in their uses. From extended one story buildings to the many-storied mill; from the iron works to the cotton mill, and the blacksmith shop to the tool room, there is an ever-changing set of conditions and requirements.

The foundry, with its warm castings generally remaining over night, is easily heated, as compared with the granite cutters' shed. The machine shop, with its large masses of cold iron and with little heat generated by the friction of moving machinery, requires vastly more heat than the spinning room of a textile mill, with its thousands of revolving spindles and immense amount of shafting and belting.

The planing mill, with its capacious exhausters, removing not only the chips and shavings, but large quantities of warm air, is, like the picker room of a cotton mill, a much more difficult place to heat than a well built and tightly closed machine shop.

Furthermore, the boiler maker, molder or blacksmith, who has to work in a temperature that would be barely comfortable to an employee in a watch factory, will certainly complain of the excessive heat.

All these, and a thousand other points, have to be considered in satisfactorily heating a factory. Too often, however, it seems to be merely a question of cubic contents and exposure, with scarcely a hint as to character of construction, or the uses to which the building is to be put.

ONE-STORY BUILDINGS.

Of all open-storied buildings the most difficult to heat for a given cubic contents are, as a rule, those of one story, having, as they do, the largest amount of exposure per unit of volume, and when of considerable hight requiring special care in the distribution of the air. Whenever there is a ceiling beneath the roof timbers, rapid cooling is prevented and the air is given an opportunity to roll along this surface. The most satisfactory, but necessarily the most expensive, application of the blower system in a one story building consists in conveying the heated air from the hot-blast apparatus around the entire building through horizontal pipes inside the building as near the eaves as possible, and discharging downward therefrom through branch pipes extending nearly to the floor. There is thus provided a warm barrier of air close to the walls around the entire building. By the cooling action of the walls and the windows this air falls to the floor, passes to the center of the building and escapes through cracks in the monitor or else continues at the ceiling to pass back to the walls and there unite with more fresh warm air.

With this arrangement the fan and heater is frequently placed overhead on the roof trusses in the center of the building. Whenever it is not desired to provide fresh air the movement of the air already described is accelerated so far as the upward movement is concerned, and it is readily drawn back into the heater to be reheated. In the ordinary shop the matter of heating has very decided precedence to ventilating, and it is seldom that fresh air is taken directly from out of doors. With direct heating there is in a factory practically no entrance of fresh air except by leakage, but with the blower system such a pressure is created within the building that although the air may be continually passed through the heater there is always a slight outward leakage at some points and a corresponding, although almost imperceptible, inward leakage at other points.

The economy of reusing the air is marked and self-evident. For, suppose that the air discharged from the distribution pipes must be at a temperature of 140° to satisfactorily heat the building, with outdoor air at 0°, it clearly makes a difference whether air must be raised from 0° to 140°, or from the temperature inside the building—say 60° or 70°—up to 140°. That it is expensive to thoroughly ventilate must be admitted, and this, above all others, is the reason why the factories of the present day are so far from perfect in this respect.

To return to the heating of one-story buildings: many are satisfactorily heated by the placing of a single hot air pipe

down the center, discharging at an angle downward toward the walls and floor.

SINGLE APPARATUS.

The simplest arrangement conceivable where any piping whatever is to be used is that illustrated in Fig. 1, where, in a shop 80 feet wide and 400 feet long, a single cross pipe at one end is provided with one outlet under the monitor and one under each of the sides from which air is discharged, the entire length of the building.

The popular form of machine shop, familiarly known as the "galley shop," can be treated in this manner under certain circumstances. The traveling crane, which always forms a part of such a construction, prevents the carrying of any pipes directly across the building, except at the extreme ends.

Fig. 1.—One-Story Building, Heated by Single Apparatus.

Several methods have been successfully adopted for the heating of such buildings. One of the earliest was to place a fan and heater upon the first or ground floor midway of the length of the building and near one of the side walls. From the fan brick ducts were run along each of the walls beneath the floor level, connecting with the one on the opposite side of the shop, being made through a brick underground duct. At suitable distances and between the windows galvanized iron risers were provided, each having outlet openings on the first floor and the gallery floor, so arranged as to blow along the walls, no air whatever being discharged toward the center of the building. The natural circulation of the air, however, caused it to rapidly distribute itself throughout the entire building, creating a remarkably uniform temperature.

USE OF TWO HEATERS.

Whenever the building is large enough to warrant the introduction of two apparatus they may be very satisfactorily arranged as shown in Fig. 2, whereby all crossing of the center space is readily avoided. Here the air is discharged toward the outer walls, the larger volume beneath the gallery, from pipes as indicated. These pipes extend the entire length of the building.

By the introduction of a fan and heater at each end of the building and an arrangement similar to that in Fig. 1, a volume of air may be forced from each end toward the center. Care should, however, be taken that with this arrangement the end walls are sufficiently protected by volumes of warm air.

In all these arrangements the air from the shop can be readily taken back through the apparatus and reheated.

BUILDINGS OF MORE THAN ONE STORY.

In buildings of more than one story there should always be opportunity to place the apparatus on the lowest floor or in the basement, and as near the center of the building as possible. Very few factory buildings are square, by far the larger proportion being in length from two to four times the width. Hence, while in a square building a single sheet iron pipe extending from the apparatus vertically up through building at its center and discharging the air toward all four sides will prove very effectual and economical of distributing pipe, in a rectangular building, on the other hand, these stand pipes will have to be duplicated and connections to their bases made directly from the apparatus.

The general application in such a building is shown in Fig. 3, and probably forms one of the most common arrangements adopted in wooden factories or buildings not primarily designed with a view to the introduction of the hot-blast system. This arrangement is sometimes varied by carrying up a single riser at the center of the building and extending therefrom toward the ends horizontal pipes on each floor—in all cases these pipes being close up to the ceiling, so as not to interfere with belting or shafting. The distance these pipes have to be carried toward the ends, and likewise the number of the risers with the other arrangement, must depend on the distance the air can be forced and still do effectual heating—this in turn depending on the smoothness of the ceiling and the cooling character of the walls, as well as the relative width of the building. In a certain building in which the floors are carried upon the regular floor joist about 12 inches apart, these joists being at right angles to the direction of the air current, the serious breaking up of the currents which thereby resulted was almost entirely obviated by tacking to these joists a few lengths of galvanized iron of standard width, extending in the same direction as the current, so as to form a smooth surface along which the air could slide or roll. This was far cheaper than to make pipe to convey the air the same distance.

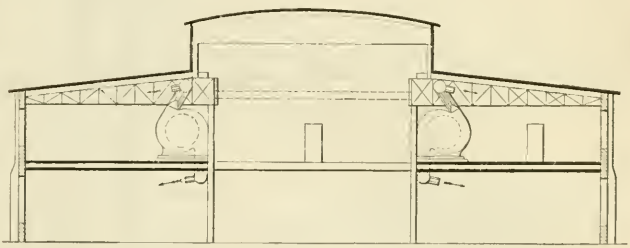


Fig. 2.—One-Story Building, Gallery Type, Heated by Two Apparatus.

Fig. 3.—Four-Story Building, Heated by Vertical Risers.

FACTORY HEATING BY THE BLOWER SYSTEM.

Sometimes when the central space in the building is extremely valuable, the pipe may be made rectangular and carried up between the windows.

As the blower system becomes better known, the builders of new factories more and more take it into consideration in their original designs. This is particularly true of the textile mills. All the prominent mill architects of New England are conversant with the merits of the system for cotton-mill work, and in their original designs, almost without exception, make suitable provision for the introduction of the system.

MILL HEATING.

The prevailing custom in this line of mill work—but applicable to all brick buildings—is to carry the heated air up on the outside of the building in special brick pilasters at proper distances apart, between the windows. The general character of such pilaster flues is indicated in Fig. 4, which shows one of the best construction, with air spaces in outside walls and with specially designed dampers at each floor. The area of the flue is decreased, as it ascends, in proportion to the area of the outlets to the various floors.

Such pilasters are usually placed 50 to 75 feet apart along one side of the mill and discharge directly across it, even if 125 feet wide. The large amount of moving machinery in a textile mill serves to thoroughly disperse the air and equally heat the rooms throughout.

Connection to the bases of the various flues is usually made by a duct from the fan running along the side wall of the shape shown or with flat top covered with plaster on wire lathing, blue stone, brick on tee irons; or quadrant in shape, spring-

ng in a quarter circle from the basement floor over to the wall.

As such mills are generally of considerable size, the fan wheel is seldom less than 6 feet in diameter, and almost, of necessity, is inclosed in a three quarter housing of sheet iron, the lower portion of the fan casing being formed in the brick foundation. A special shape of fan, rendered necessary by the existing circumstances, is represented in the cut.

Obviously, under such an arrangement of flues and ducts the heating apparatus may be either within or without the building. In large plants particularly, where there are several buildings to be heated, it is quite generally the practice to erect a special building for the apparatus.

Ventilating or outlet flues are never necessary in ordinary mill heating where the air supply is sufficient only to change the air in the building every 15 minutes. Such outward leakage as does take place is almost equally divided among all the windows with their numerous leaks and some of it even takes place through the porous walls.

SPECIAL ADVANTAGES IN TEXTILE MILLS.

In the textile mill the blower system adds still another to its advantages. The necessity of an atmosphere of stated and constant humidity for the proper working of fine yarns is well known, and many endeavors with expensive apparatus have been made to produce that moist condition of the atmosphere most conducive to success in spinning. In a certain mill such an outfit cost $2500. When the blower system was introduced in another mill of almost the same size and owned by the same corporation, the moistening system consisted simply of a rose spraying nozzle on the end of a 1 inch pipe introduced into the duct at the outlet of the fan. The cost of this outfit may be compared with that in the first mill with considerable to the credit of outfit No. 2.

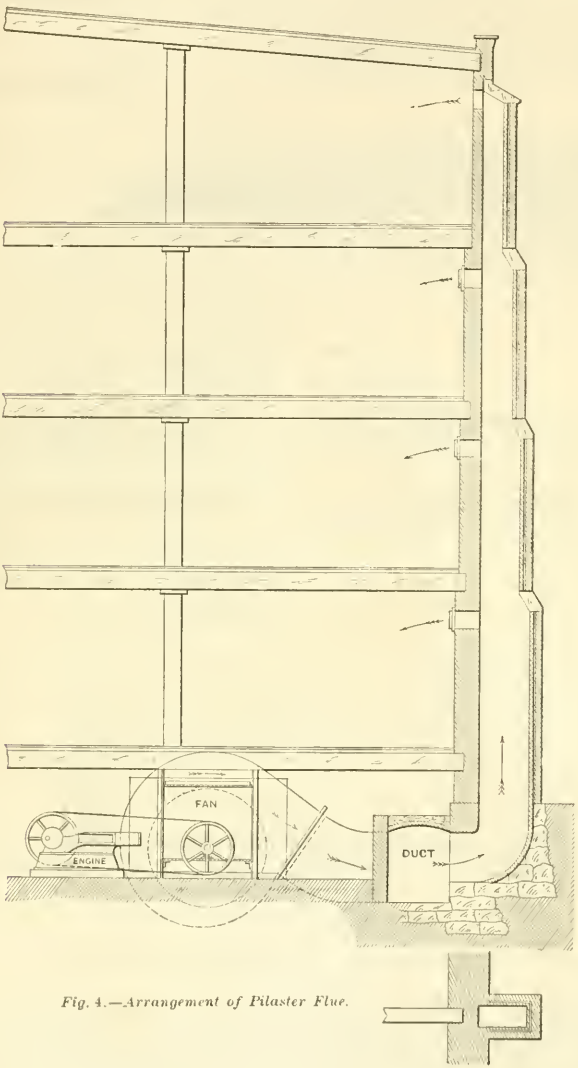

Fig. 4.—Arrangement of Pilaster Flue.

FACTORY HEATING BY THE BLOWER SYSTEM.

It was remarked of this same mill by a State inspector that, notwithstanding that no direct supply of fresh air was taken from out of doors, yet the atmosphere was far purer than in many of the public halls of the State.

In many cases, where from humanitarian or even from mercenary motives the air supply is taken from out of doors—particularly in shoe shops—the increased healthfulness of the operatives is noticeable. And the fact is further appreciated, that more and better work can be done in a pure and comfortable atmosphere than in the almost proverbially "stuffy" atmosphere of the ordinary factory.

IMPROVED VENTILATION.

The attention that is being given to this matter in the legislative action of our progressive States is at the present time noticeable to a marked degree, and goes hand in hand with the provision of safeguards against accident to the employee.

In some factories certain apartments require much more thorough ventilation than others. This is noticeably true of match factories, where, with the introduction of the blower system the air change in the rooms where fumes of sulphur and phosphorus are prominent is limited to five minutes while 20 minutes is the limit for the remainder of the building. If air of the same temperature were forced to all apartments alike, serious overheating would result in the rapid change portions. To obviate this, the apparatus is so designed that the air to the various apartments is properly tempered by mixing it with the requisite volume of cold air which has not passed through the heater.

While the presence of moist air in the textile mill is an advantage, a similar atmospheric condition in a machine shop with much bright work in progress would be a serious injury.

Fortunately the process of heating is such as to render the air leaving the ordinary apparatus (without moistening device) very avaricious for moisture and machine manufacturers have remarked on the absence of "sweating" on their bright work wherever the blower system is used.

In the lumber mill the same apparatus may be employed to heat the mill and dry the lumber. In small planing mills, furniture factories and the like, this is of great advantage. New adaptations of the flower system in factory heating are daily coming to view; manufacturers in certain specific lines are leaving its special adaptability to their particular line; the system, its operations and advantages are becoming better understood and its rapidly increasing adoption is a certainty of the future.

HEATING NOTES.

THE HERENDEEN MFG. COMPANY, Geneva, N. Y., send out postal cards directing attention to the Furman boiler of their manufacture, the merits of which are briefly alluded to.

IN AN ARTICLE in *The Metal Worker* of March 11, entitled, "Ventilation of Public Schools," the number of units of heat required to raise 1,080,000 cubic feet of air from zero to 65° F. were wrong, as stated. Cubic feet instead of pounds of air, were used in the calculation. The number of units of heat required to raise the quantity of air to 65° F. should have been 1,348,303. The weight of air is taken at 32° F., or about a mean between zero and 65° F.

THE MICHIGAN ASSOCIATION of Steam and Hot Water Fitters was organized March 16 at Detroit, Mich. This organization was the result of action taken by several prominent Michigan firms to bring about closer relations between the members of the trade in all parts of the State. Secretary Reynolds of the National Associa

tion of Master Steam and Hot Water Fitters, who was present at the meeting, spoke of the necessity of organizing to protect themselves against the manufacturers selling direct to consumers. The officers elected for the Michigan Association were as follows: President, Robert S. Sproul, Grand Rapids; vice-president, J. H. Crumley, Detroit; secretary, W. C. Weatherby, Grand Rapids; treasurer, James Meathe, Detroit; executive committee, T. F. Hertzel, Ann Arbor; C. W. Light, East Saginaw; J. A. Wheeler, Kalamazoo.

THE NASHVILLE MACHINE COMPANY, Nashville, Tenn., issue an illustrated catalague of the G. & J. R. Bolton Improved Hot Water Heater, which they manufacture. This heater is fully illustrated in the pages of the pamphlet, general and sectional views being presented, as well as full descriptive particulars. The main features of the heater and its advantages are also alluded to, and a table given of sizes, weights, and other particulars, including prices. At the close is a list of names of some of the users of these heaters.

F. P. HAMILTON, for a number of years superintendent for Dewstoe & Schneider of Cleveland, has connected himself with the Capitol Heater Company of Detroit. He will represent that company in Northeastern Ohio, North western Pennsylvania and Western New York, selling the Capitol and Bolton hot water heaters.

THE HERBERT STEAM HEATER COMPANY have purchased a piece of vacant ground on Shields avenue, 150 x 150 feet, near Thirty-third street, Chicago, on which they will begin at once the construction of a large plant for the manufacture of heating boilers. The ground is on the line of the Pittsburgh, Fort Wayne & Chicago Railroad. The company is composed of M. E Herbert, formerly of Chicago, but who has been successfully engaged in manufacturing at St. Joseph, Mo., for 15 years, C. J. Herbert and Louis Plath. The capital stock is $50,000. Plans for the first building to be erected have already been prepared, and construction will be commenced at once with a view to its completion by May 1. The building will be 50 x 125 feet in dimensions and a story and a half high, the section containing the offices being two stories high. It will be constructed of brick and stone, and temporary walls will be put in at one end, so that it can be easily extended as the growth of the business warrants.

THE MONITOR STEAM GENERATOR MFG. COMPANY of Landisville, Pa., report business brisk. They are makers of the Monitor Instantaneous Steam Generator and Positive Hot-Water Circulator, and their business is principally with the trade, they only taking contracts for heating in sections where the services of a practical fitter are unattainable. Their capacity is from two to three finished boilers per day, furnishing employment for about 45 hands.

THE ANTHRACITE BRASS WORKS of Tamaqua, Pa., have started a factory for the manufacture of stop cocks, brass castings and other goods. They also deal in plumbers' goods, and undertake steam heating. As a specialty, they are turning out large quantities of wrought-iron nipples and long screws, which they claim to be able to put upon the market at exceptionally low prices.

THE MODEL HEATING COMPANY, Stewart Building, New York, issue an elaborate pamphlet entitled, "Circulation at the American Institute Fair." The publication contains some 30 pages, and presents in an interesting way the exhibit of the company at the American Institute Fair, showing the circulation of hot-water through radiators and pipes in various positions. There is also a description given of the Novelty Circulator, models of which operated the radiators and pipes at the exhibit. The cuts are well executed and the publication is an interesting example of trade literature. Tables of dimensions, ratings, prices, &c. of the Novelty Circulator are likewise presented.

Errors of Experts.

In the course of a recent lecture before the British Institute of Marine Engineers at Cardiff Joseph Williams gave some striking instances of erroneous opinions expressed by experts, from which we extract a few of the most emphatic as examples of how even the greatest minds are not always able to grasp the full possibilities in their own particular branch of science or study:

James Watt, it is said, attempted to get an Act of Parliament passed to prevent the further introduction of Trevithick's high pressure engines, and for the latter's continued advocacy of the use of high-pressure steam, the mild Caledonian philosopher forgot himself so far as to say openly that the great Cornish man deserved hanging. It is an instructive commentary on the prescience displayed by such a great engineering authority, to observe that it is not uncommon to find steam engines of the present day working with a steam pressure five times greater than Trevithick adopted to work the first railway engine at the Penydarran Iron Works 26 years before the advent of George Stephenson's famous "Rocket" at the Rainhill competition. There can be little doubt that from Trevithick's achievements Stephenson drew the inspiration which his genius and industry elaborated into his magnificent success.

Reference to the "Rocket" reminds one of another rather strongly expressed opinion concerning the conditions which were formulated to govern the celebrated engine trials at Rainhill. Mr. P. Ewarts, who, though not so distinguished as the others, is said to have been a gentleman of some eminence in Liverpool, and to have subsequently filled the office of Government Inspector of Post Office Steam Packets, declared that only a parcel of charlatans would ever have issued such a set of conditions; that it had been proved to be impossible to make a locomotive engine go at 10 miles an hour; but if it ever was done he would eat a stewed engine wheel for his breakfast. About the same time a writer in the *Quarterly Review* remarked: "What can be more palpably absurd and ridiculous than the prospect held out of locomotives traveling twice as fast as stage coaches? We would as soon expect the people of Woolwich to suffer themselves to be fired off upon one of Congreve's ricochet rockets as trust themselves to the mercy of such a machine going at such a rate."

A speed of 60 miles an hour is now regarded with equanimity, and it has been satisfactorily demonstrated that upward of 80 miles an hour is possible.

When that grand old mechanic, William Murdoch, among his many other useful inventions, discovered the utility of coal gas, and advocated its general use as an illuminating agent, his idea was ridiculed by the most eminent scientific experts of his day, the foremost among them being Sir Humphry Davy, who sarcastically suggested the idea of using the dome of St. Paul's for a gas meter, but "facts before philosophers" was found to be true in this instance as in that of innumerable others, and Murdoch's experiment with the bowl of a tobacco pipe filled with small coal was the germ which eventually developed into one of the vastest industries of our time, which now furnishes daily employment to hundreds of thousands of workmen and creates an annual demand for millions of tons of coal.

Robert Stephenson (who unlike his great father) had received the benefits of a liberal scientific education, and who occupied a place as an expert in the very foremost rank of modern engineers, thus expressed himself in the House of Commons with regard to the project for cutting a canal through the isthmus of the Suez: "I have surveyed the line, I have traveled the whole distance on foot, and I declare there is no fall between the two seas. Honorable members talk about a canal. A canal is impossible—the thing would only be a ditch."

The Suez Canal has since become one of the greatest commercial highways between the nations of the world.

That eminent scholar and scientist, the late Dr. Lardner, pronounced dogmatically in 1835, that any attempt to send a steamboat across the Atlantic would prove an absurd delusion; but on subsequently modifying his views, he fixed the ultimate size and power of Atlantic steamers at 800 tons and 200 horse-power. The inaccuracy of both these predictions was demonstrated within a period of three years from their utterance, by the crossing of the paddle steamer "Great Western" of 1340 tons and 440 horse-power.

The great ocean "greyhounds," "New York" and "Paris," which have recently been added to the mercantile navy of the United States, possess 10,500 gross tonnage, with 18,000 indicated horse power, and the end is not yet. These figures are both to be overtopped by the last new liners now being fitted out for transatlantic service.

Numbers of other instances of similar miscalculations might be quoted, as showing that no man, however great his intellect, is infallible or omniscient. Science has constant surprises on hand, and what is deemed impossible to-day may to-morrow be placed in the catalogue of achievements.

The Supreme Court of Tennessee recently rendered a decision which is of very broad and general application in the principles it involves. It appears that the Wholesale Grocers' Association of Nashville had bound its members not to buy from any importer or manufacturer who sold to retail merchants. The plaintiff, a retail grocer, brought suit against the association for $25,000, alleging that this combination of wholesale grocers had damaged his business, diminished his profits, and subjected him to great inconvenience and trouble, and that the compact made and enforced by the wholesale grocers was in restraint of trade, and therefore against public policy and unlawful. The trial judge charged the jury that such an organization was illegal, and that the plaintiff was entitled to recover any actual damage he had suffered by reason of such combination. In sustaining the decision on these points the Supreme Court went further, and held that if such an agreement was found to exist and the plaintiff had suffered from it he was entitled to a verdict or nominal damages which would carry with it the costs of the action.

William R. England, Chicago, Ill., has been granted a patent on a pipe coupling, consisting of one member provided with a longitudinally corrugated spigot and another member having an interiorally longitudinally corrugated bell. The corrugated portion of the spigot and bell interfit with each other, and an annular chamber for packing is provided.

The companies in the northern part of New York engaged in producing mineral pulp are to be consolidated in one corporation having a capital of $2,000,000.

PLUMBING AND GAS FITTING.

Organizing a Health Board.

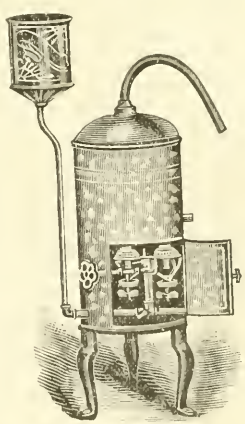
From C. A. B., *Pennsylvania.*—Please inform me through the columns of *The Metal Worker* how a town of 3000 inhabitants can go about it to secure a health board. Are sanitary inspectors usually appointed by the boards of health and are these officers usually paid anything? Where must a plumber apply for a license and examination, and what is the cost?

Answer.—Through the efforts of the Master Plumbers' Association of Philadelphia a bill was passed in the Pennsylvania Legislature in 1885 authorizing boards of health in cities of the first class throughout the State to present rules and regulations for the construction of house drainage, the registration of master plumbers and the construction of cesspools. The act consists of only three sections—one defining the general scope and purpose of the act, another conferring the power of supervising plumbing and house drainage on the respective boards; the sanitary inspectors to be paid such compensation as the councils of these cities shall approve, while the third provides the penalties for refusing or neglecting the requirements of the sanitary rules when promulgated. The bill, though intended only to apply to cities of the first-class, is held to be permissive so far as smaller places are concerned, the formation of local boards of health being vested in most instances in the local council or governing board. When the Board of Health is formed, if there is a sufficient number of plumbers in the town or district, rules can be formulated under which sanitary inspectors may qualify for position and plumbers prove by examination their fitness to conduct a plumbing business. As the Health Act of 1885 is in better working order in Philadelphia than in other cities in the State, owing to the good work of the Association of Master Plumbers, we give the methods in vogue in that city for the enforcement of the provisions of the act as follows: Under Section 1 authority is given "to provide for the registration of master plumbers and persons engaged in the plumbing business in said city." Before such registration can be effected the applicant must undergo an examination as to his fitness. The Registration Committee of the Master Plumbers' Association co-operate with the Health Department in the matter; but the examination of the applicant must be made by the chief officer of the Drainage Department of the Board of Health. A schedule of questions on the practical and scientific character of the work of plumbing and drainage is presented to the applicant, and if his correct answers fall under 70 per cent. he will not receive a certificate of registry, nor be permitted to engage in business in Philadelphia. Failure at the first examination does not deprive him of another trial, which, however, is deferred for three months, but if the second examination results in failure then he is laid off indefinitely. If successful he obtains his certificate, but whether there is any fee attached to the issuance of the license or otherwise, we are not in a position to state. There does not appear to be any fee called for in the rules promulgated by the Health Board in February, 1886, but refusal or neglect to comply with the rules is mentioned in the statute and subjects the offending plumber to "a fine of not more than one hundred ($100) dollars or to undergo an imprisonment not exceeding one year or both, in the discretion of the court." The sanitary inspectors in Philadelphia are appointed under the act by the Board of Health (*vide* Sec. 2), and are paid a salary of $1200 per annum.

It should be borne in mind that the act of the Legislature of June 30, 1885, applies to the entire State, and not to any particular location or city.

The Surprise Gasoline Portable Bath Heater.

The accompanying cut illustrates a portable bath heater adapted to use gasoline as a fuel that has been brought out



Surprise Gasoline Portable Bath Heater.

by McCahan & Co., 8 North Central avenue, Baltimore, Md. The gasoline heater is made the same as the gas heater of the firm, except that it has longer legs and a gasoline tank. A twin burner, operated with one crank, is attached to the case. The water inlet is near the bottom of the steel boiler, and hot water is delivered through goose neck at the top. The boiler, we understand, will resist any ordinary water pressure, and can be connected with any water supply, either by hose or iron pipe. Where connected by iron pipe permanently the hose and goose neck are not necessary, and the cost of the apparatus is less.

Range Boiler Emptied Through Relief Pipe.

From W. T., *New York.*—As well as can be judged from the sketch presented in *The Metal Worker* of May 18, the displacement of the hot water in the boiler through the relief or expansion pipe and the substitution of cold water therefor, as explained by your correspondent, "C. Q. A.," are due, in my opinion, to two causes, each more or less identified with the other—viz., the insufficient altitude of the tank above the boiler, and the use of a relief pipe, which is, consequently, too limited in hight to avoid being mixed up in the trouble. Your correspondent, I note, has fallen into an error in the first instance in attributing the effects he complains of to the fact that the water will syphon back into the supply tank through the vent pipe. This is an impossibility when the respective position of the two vessels are taken into consideration, as syphonage cannot take place where a liquid has to be drawn from a lower vessel into a higher one. In the illustration, as it appeared, the range boiler is the lower vessel, the supply tank the higher, and if syphonage had to be brought into operation as a means of transferring water from one to another of these vessels, the long leg of the syphon should be inserted in the boiler instead of in the supply tank. It is, therefore, clear that some other cause than syphonage must be made responsible for the emptying of the lower vessel, viz., the boiler, into the higher one, the tank. Now, as to the cause of the trouble. It is shown by the explanation appended to illustration that the tank said to contain 27 barrels of water —say, 810 gallons—is set on a level with the top of the boiler. The measurements of the tank are not given, but probably, judging by its alleged capacity, 6 feet in length, 4½ feet in width and 4 feet in hight, would suffice. From the top of the boiler an expansion or relief pipe is carried down to and under the floor and again upward to above the tank, where it is finished with a return bend. Through this pipe the emptying process complained of takes place—the water in the boiler as soon as heated commencing to discharge into the tank, its place being, of course, taken by the cold water. The agency through which this undesirable effect is accomplished is not, in my opinion, difficult to find out. It should be remembered that water is at its greatest density at 40° F.—that is, the greatest quantity can be stored in a given space at that temperature. If a boiler is filled with water at this density, and the water afterward be heated, expansion will take place—that is, the heated water will increase in bulk, and if there is no other relief afforded it will seek it through the cold-water supply pipe. If, as in the case cited by "C. Q. A.," a relief pipe is supplied, the expansion will naturally be through that pipe, and the question then comes up, what is the storage capacity of that pipe for the amount of water displaced by the expansion process? Hot water, as we understand the term, expands about 1 gallon in every 24—that is, there must be some receptacle provided equal in space to the duty of storing that amount of water after it is forced out of the boiler. If the boiler, as illustrated, is of the capacity of 40 or 50 gallons, the increased space necessary will be for the storage of either 1⅔ or 2 gallons, as the case may be. Is it not, therefore, fair to assume that

considering that "C. Q. A.'s" tank is on a level with the top of the boiler, the necessarily short expansion pipe is not able to store all of the water displaced in the heating process—that it is forced out in this way into the tank until the expansion is checked by the resultant inflow of cold water and the reduction of the temperature in the boiler? This is the view I take of it, and I do not see how the defect can be remedied unless, first, raising the tank sufficiently high to give the necessary lengthening of the relief pipe; second, extending the relief pipe as much above the tank as possible; and, third, doing away with the relief pipe altogether and letting the expansion find its own relief through the supply pipe. If the boiler were supplied from street pressure, "C. Q. A." could not use a relief pipe unless he carried it above the roof, which would not be a likely thing, and he would consequently have to dispense with its use. It is probable that this view of the cause of the trouble will be questioned, and that it will be urged that, as water exercises a pressure equally on all sides, it does not follow that the increase by expansion should seek an outlet in one direction only—that is, by the top of the boiler into the relief pipe. To this objection, if urged, I would say in advance, that the tendency in hot water is to rise, and that in my opinion, in obedience to this natural law it will seek the needed relief in that direction while there is no resistance, in preference to maintaining an unnecessary struggle with the body of cold water at the bottom of the boiler. As a proof that an expansion pipe can be dispensed with without danger, I may point to hundreds of houses in this city where no such pipe is in use.

Alleged Errors in Plumbing.

From H. S. P., *Paterson, N. J.*—I notice among the "Errors in Plumbing Practice," which are set forth in *The Metal Worker* of March 18, breaking joints and using quarter bends on horizontal lines are placed on the condemned list. I cannot understand why, and I write for information. I am a builder and take contracts in their entirety, which includes the plumbing work, and as I have to rely on the plumber to whom I give the work, and who constantly commits these alleged errors, I will be glad to learn something that I do not know. Let us suppose that I have a cellar bottom through which the house drain is to run under the floor and to get out to the sewer through a certain point. In digging the trench we strike a "snag" in the shape of a rock which we cannot displace, but which we can get around by breaking the joints, as you call it, in four or five lengths of pipe, by which means we get the required deviation and can get around the obstruction. Is this a better or worse plan than using a couple of quarter bends so as to get around the "snag" aforesaid? It seems to me a better and in fact the only one advisable, because by the other alternative the use of the quarter bends will not be as efficient. What would be your suggestion? Would you use offsets instead of the quarter bends? Or how would you get over the difficulty?

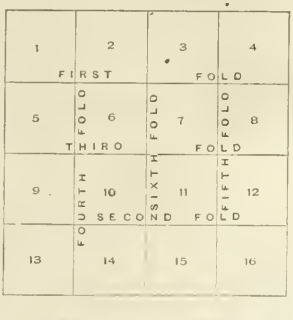
Answer.—It is a difficult thing at all times to give a definite reply to a hypothetical question, but we will endeavor to satisfy our correspondent. Three methods appear to be open by which the breaking of joints can be avoided: First, the plumber should thoroughly study the situation, and see if he could not, by the use of eighth bends, effect the necessary deviation—for instance, the drain pipe should be laid in a straight line to a given point. An eighth bend and a length of pipe, more or less, inserted at the proper place, would bring the drain in such a direction as to clear the obstruction, when the insertion of another eighth bend would throw the drain into a straight line again. A second plan would be to use a Y-branch on the line at such a point that an eighth bend inserted in the branch would bring it into line outside the obstruction, the mouth of the Y being meantime plugged up. This would avoid the breaking of joints or use of quarter bends. A third plan, the one of last resort, would be, if compelled to use quarter bends, or an offset, to use, instead, two one-eighth bends in place of one quarter bend, or four one-eighth bends in all, to curve the pipe so as to bring it around the obstruction. In theory the two quarter bends should be the same as the four one-eighth bends: but in practice, the latter make a much rounder joint or bend, and there is no sharp angle to interfere with the flow of the sewage.

Any of these three methods would be preferable to the broken-joint plan, by which the smoothness of the interior of the pipe would be completely destroyed. A portion of the spigot end of each length of pipe protruding inward at an angle would present an obstruction to the passage of the sewage. It also prevents the even calking of joints all round.

How to Make a Plumber's Wiping Cloth.

From A. D. E., *New York.*—Will *The Metal Worker* kindly afford some light on the proper method of making a plumber's wiping cloth, the material to be used and how it should be folded?

Answer.—The material used is strong ticking, of which sixteen folds are necessary for a good cloth. The appended diagram will enable our correspondent to make the folds, which must be evenly done. The size of the cloth when made up, as our correspondent knows, varies according to the use to be made of the completed article, varying from 2 to 6 inches square. As the latter is most used, we will select it by way of illustration. A piece of ticking 24 inches square, in order to serve the purpose, is marked out in imaginary squares of 6 inches. The first folding operation is to fold the portion represented by 1 to 4, inclusive, over that marked 5 to 8. The next fold places that portion represented by 13 to 16, over Nos. 9 to 12. These two double folds are again placed together, and the result so far is one long strip of four folds. The folding of this strip by first turning over the extreme ends, and then one other fold, completes the operation and gives a square of ticking of 16 folds, 6 x 6 inches, ready to be sewed carefully at the ends in such a manner that the stitches will not come in contact with the solder. The folded cloth is then thoroughly soaked in tallow, when it becomes a plumber's wiping cloth. It should be stated here that the first soaking is not sufficient; the process must be constantly repeated.



How to Make a Plumber's Wiping Cloth.

Setting Range Boiler.

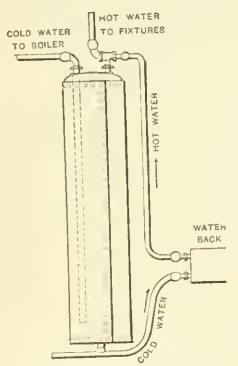
From W. H. S., *Bayfield, Wis.*—I noticed in the plumbing department of the issue of January 7, 1893, an article from "Young Mechanic," on the correct way of connecting range boilers to water fronts. I have connected quite a number of range boilers all in a similar manner, as shown by Fig. 2, and have never had a pipe burst at the bend B, shown in sketch, and of which "Young Mechanic" complains. I use the highest boiler stands made by a prominent manufacturer. As a general thing the cold-water supply pipe from the boiler has a rise of 2 or 3 inches to the water front. If Fig. 1 is the correct way and better results are obtained from it, why don't manufacturers of boiler stands make them high enough so that the boiler can be set as Fig. 1 shows, and not have "Young Mechanic," or any other plumber making wooden boxes to set the stand on in order to have the pipes in the correct position? It seems very strange to me that all the boilers I have seen set up by master plumbers should be wrong as regards the position of cold-water pipes from the boiler. "W. F. T.," in the issue of January 14, says the only defect in the sketches submitted by "Young Mechanic" is the sharp bend at B, Fig. 2. The usual couplings sent with a boiler are four. One of these is straight for the bottom and the other three are short right-angle bends. This, I infer from "W. F. T.'s" letter, interferes with or impedes the circulation in the hot-water pipe. I would like to know what kind of couplings "W. F. T." uses on the side of a boiler other than bent couplings sent with the boiler?

Answer.—Replying to our correspondent's questions, beginning with the last one, it is often advisable to discard the bent coupling and to use a straight one to which the lead pipe can be joined, a gradual bend in the lead pipe being preferable to the sharp sudden bend offered by the right-angle couplings our correspondent mentions. Although the position and manner of connecting a boiler shown in Fig. 1 and submitted by "Young Mechanic" we regard as an ideal arrangement, we are constrained to admit that most boilers are not (owing to the conditions of each case) connected in this manner. The standard sizes of boiler stands are 18 and 21 inches in hight. It can easily be seen why it would be impossible to have a stand of just the right hight to meet the requirements of every individual case owing to the fact that ranges are of so many different hights. Another point is that in city flats, as in the city of Chicago, range boilers are often connected and used in kitchens as high up as the second or even the fourth story. Very often the pressure of water from the city mains is not of sufficient power to force the water to the fifth story. This consideration makes it necessary to have the top of the boiler as low down as possible; therefore the lowest stand one can put under it must be used. The methods shown by Fig. 2 (if the pipes, connections and the water back are proportionate to the boiler) will give fairly

good results providing the pressure of the cold-water feed from the boiler is ample to raise the water so as to fill the water back and connection to the boiler and fixtures throughout the house.

Kitchen Boiler Connection.

From N. S. P., *New York.*—I do not quite agree with conclusions in your reply to "C. C.," Chicago, in *The Metal Worker* of February 25, as to the proper point of connection of the return (hot-water) pipe from water back, because of personal experience in that direction which agrees with that of the Milwaukee Gas Stove Company, as published in your issue of March 11. At the same time I must dispute the correctness of the claim presented by the last-named company, that the idea of connecting the hot-water return pipe at top of boiler originated with them three years ago, because I have been experiencing the benefits of that method of connection for more than ten years. When I purchased my house about that time the boiler was in position but failed to give satisfaction, as no hot water could be drawn from it for a considerable



Kitchen Boiler Connection.

time after the fire would be lighted in the morning. My plumber, who is well known as one of the leading members of the Master Plumbers' Association, at once undertook to remove the cause of dissatisfaction and made changes which were certainly new to me. He took out the hot-water return pipe from the usual side opening in boiler, which he had plugged up, and carried the pipe upward to top of boiler, where he had inserted a T, to one branch of which he connected it. From the other branch of the T he took his hot-water supply pipe for the fixtures through the house, and I can state positively that since he made the change there has not been a particle of trouble with the hot-water supply. He does not claim originality for his method, as it was well known at the time as the Creque method of connection. He maintains, however, that the water in the boiler will heat more rapidly by having the hot-water return pipe connected at top instead of side of boiler, and as he has given me satisfactory proof that he is correct, it is only right that I should concur in his opinion. I inclose diagram of boiler connection.

New York Gas Companies.

As illustrating the immensity of the gas interests of "Greater New York" a map published by the *Progressive Age*, with its issue of March 15, is of very considerable interest. The map, which has been gotten up with great care, shows the location of the different gas works and holders of the New York and Brooklyn gas companies, representing a total annual output reaching the enormous figure of 14,779,000,000 cubic feet. To the gas engineer the map should be of great value in giving him a perfect knowledge of existing conditions in the important industry of gas manufacture and supply in the metropolis. The map takes in the whole of Manhattan Island, with Brooklyn and a considerable portion of Long Island; embracing the territories of 16 gas companies which supply the cities and suburbs of New York and Brooklyn. From the details furnished by our contemporary we learn that an aggregate capital of $77,993,000 is invested in the gas manufacturing corporations of New York. Of these, the Consolidated Gas Company alone—a combination of a number of concerns, including the Municipal, the New York, and the Manhattan—hold an estimated capital of $39,000,000. This company, who stand first in importance, have an annual output of 8,000,000,000 cubic feet, and a largest daily output of 40,000,000 cubic feet. The next greatest concern is the Equitable, with a yearly send-out of 1,500,000,000 cubic feet of gas; the remainder all falling short of ten figures. The growth of the gas business in New York, despite the increasing use of electric lighting, is said to be rapid; and consolidation of all these vast interests is regarded as looming in the future.

Plumbers' Soil.

From R. L. S., *New Haven, Conn.*—Can you give me information as to how plumbers' soil is made, what the ingredients are and in what proportions they are used?

Answer.—The materials for making plumbers' soil are glue water and lampblack. Make a thin solution of the glue by boiling it slowly in water until entirely dissolved Then stir in lampblack sufficient to make the mass of the consistency of paint, simmering the compound over a slow fire for about a quarter of an hour. The testing of the article is done by applying it with a brush to a piece of lead and allowing it to get cool. The lead is next bent backward and forward in the hand in order to judge of its adhesiveness. If it cracks while the lead is undergoing the bending process, it is found to have too large a proportion of glue and is condemned. If it does not crack and adheres to the lead, it is considered all right.

Latrines of the East.

In a recent illustrated article published in the *American Architect*, of which we present an abstract, Edward S. Morse describes at length the ways of the people in Eastern lands in disposing of human excreta and the conveniences used by them. In most of these countries sanitary science is as yet almost wholly unknown, and their system of latrines is, to put it mildly, very primitive, not to say filthy in the extreme. That cholera should take its origin in China, Eastern Russia, and other parts of the Asiatic continent, is not surprising when we contemplate the methods pursued by the teeming millions of the East in the matter of sewage disposal, and its relation to drinking water, as detailed by Professor Morse and other authorities.

CHINESE METHODS.

The Chinese are, with the possible exception of the Russians, thought to be the most depraved of people in this respect. Their cities are said to be the filthiest places imaginable. In the better class of houses each room is provided with a covered wooden bucket for latrine purposes. These buckets are emptied each day by men who come round for the purpose, and the ordure is removed in open pails through the streets, being dumped into boats on the canals. These boats on being filled are towed away to the rice fields, where the material is spread over the earth for manure. It is said that much of the filth goes into the canal, through careless handling, and as this canal has no tide the result is that it mixes with what is generally the only source of drinking water. Moreover, the night soil manure on the rice fields is to a large extent washed into the canals by rains. Earthen jars imbedded in the ground are also used in the yards of some houses in China. These are covered by a low frame work of wood similar, as Professor Morse observes, to "the primitive simplicity of similar conveniences all over this country;" and these are periodically emptied. These jars sunk in the loose soil soon pollute the ground and, finally, the water supply. In Canton the latrines are public. Wooden buckets are used in the house by the women, but the men use the public places, which are to be seen in all quarters. These are described as a row of stalls in the filthiest condition imaginable, closed by doors. A deep stone gutter runs the length of the place, close to the wall. Across this in each stall are secured two narrow planks, and just in front a narrow gutter runs to carry away the urine. Widely distributed through the city are earthen jars imbedded in the ground, which are the public urinals. In Corea, a traveler has recorded that he saw women washing clothes in a stream, and "though the stream was low, and its bed served as a dung heap, water was also being carried away from it for household uses, and there was evidence on every side that, according to all rules of sanitation, the population should by right have ceased to exist."

JAPANESE CLEANLINESS.

Japan forms a striking contrast to China and Corea in these matters. Not only does every house have its privy, but there are public latrines as well, and the conveniences and general arrangements are scrupulously cleanly. In the country one often sees, in the neighborhood of the poorer class of houses, a covered place closed by a low door. Receptacles in the form of large jars or buckets are found near the rice fields. The Japanese are very careful to preserve the material for fertilizing purposes, and it is all transferred into the country, leaving the shores of a city absolutely pure. The general features of a Japanese privy are described by Professor Morse as follows: "The receptacle consists of a large earthen jar or the half of an oil barrel. This is sunk in the ground and emptied every few days by means of a long-handled bucket from the outside. The men who are engaged in this work have their regular routes and pay for the privilege. It seems incredible that a large city like Tokio, with its million of inhabitants, has this service performed in the most thorough manner. Indeed, so valuable is this substance that in Hiroshima, I was informed, in the renting of the poorer houses, if three persons occupied a room together the value of this product paid for the rent of one, and if five occupied the room no rent was charged."

In many places the privies might properly be called cabinets, so exquisitely clean and beautiful is the wood work inside and out. Some doors are inlaid in designs of different colored woods, the whole affair being a dainty bit of cabinet work.

The urinal is usually of wood, though porcelain ones are often seen. The wooden ones are in the form of a tapering box secured against the wall of the closet. Sometimes sprays of a sweet-scented shrub are placed in these and often replaced. The refinement of the Japanese in these matters is shown by the various names applied by them to the privy, such as *Setsuin*, snow-hide, *Chodzu-ba*, place to wash hands, *Ben-jo* and *Yo-ba*, place for business, *Koka*, back frame, &c.

OTHER EASTERN SYSTEMS.

On the Malay Penisula a few closed privies are seen among the natives. By those living over the water (as many of

these people do live) a shelter, removed from the house, and supported on poles, is provided. The floor of the convenience is constructed of a few boards, with wide interspaces between. On dry land a hole is excavated, and sometimes an earthen jar imbedded, in the ground, over which a few boards are placed.

In Siam the privy is usually erected on a frame work over running water, being a mere staging without covering. This custom seems to prevail among all the people of those parts from Bangkok to Singapore. Unfortunately, however, the water in which the excreta is emptied is usually the source from which the household water is drawn. The dissemination of disease is thus encouraged in these regions. The natives of Sumatra and Java follow the same general principles in erecting their conveniences over running water.

In parts of India, not immediately under British influence, gardens and open lots form the only convenience, pigs acting as scavengers. In Ceylon, the wealthier classes have latrines near the house, but the poorer classes resort to the garden or retreat to the underbrush near by. In many of our Southern and Western States, outside the larger towns, and in Central and South America, the same custom prevails.

RUSSIAN CONDITIONS.

In Northern Russia the habits of the natives are very filthy, and no conveniences of any kind are used. In Southern Russia, on the contrary, little houses are constructed in basket-work fashion and of basket material—roof, door and all. Within is a circular opening, or a wide interspace between the planks forming the floor. If anything would warrant a rigid quarantine against the Russian emigrant, the account given by Mr. Morse of the state of Russian towns, and especially of inns and public places, would certainly justify such an attitude. Unfortunately, the whole description is too long to quote in this article; suffice it to say that the interior of the public establishments "displays an inexhaustible store of disgusting foulness, eloquent signs and specimens of which cover the walls, the windows, the tables, the floors and the kitchen. The whole place is permeated with abominable smells and venomous exhalations." The unpaved yards of these places are merely great dung heaps, spreading disease germs broadcast. A native Russian writer in a European journal says in this connection: "The hygienic condition of yards, streets and public places is on a level with that of private dwellings, and the excreted refuse of houses, which, in European towns, is made to disappear as rapidly, opportunely and mysteriously as a suspected subject of the Czar's, is left as inviolate as if it were a sacrifice to the unclean gods. 'Even in our two capitals, the method of removing refuse and impurities is so antediluvian that it would be an abuse of terms to allude to it as sanitation. In the most favorable cases, the "system" consists in digging a big hole in the yard of every house and throwing into it all the garbage, offal, &c., and leaving it undisturbed for months, and for longer terms than months, until at last it is carted off in boxes and barrels to some place outside the city. It is easy to imagine to what extent the soil is permeated with filth and the atmosphere vitiated with miasms, and in what an Eldorado the microbes of infectious diseases revel. And it must be noted that even this "system," defective as it is, is followed only in favorable cases—*i. e.*, when private houses are provided with closets. As to the "system" pursued when there are no water pipes and water is dear, it is better not to speak of it. It is a horror.'"

In other parts of Russia, we are told, "cesspools are constructed under the floors of the houses; the river banks consist of solid filth, sprinkled over the top with sand; the cities are saturated with filth, excreted impurities oozing into the rivers, in which carcases of dogs and cats float; foul sewage is thrown into the streets," and such like tales of horror, showing indescribably bad sanitary conditions to exist to-day in the dominions of the Czar.

CUSTOMS OF VARIOUS PEOPLES.

The Greeks are stated to be almost as vile in their habits as the Russians, though the hot climate tempers their offense somewhat. The Tartars do not remain long in one place; they are obliged to keep moving to avoid the accumulations of filth that take place where they encamp. Various Siberian tribes are similarly circumstanced. In Egypt the natives resort to the desert, where the sun, aided by swarms of insects, soon obliterates all traces. In Turkey, latrines are common in houses. They consist of a large slab of stone or marble, with a hole in the center and grooved channels for running water inclined toward the hole. No seats are provided, but buckets of water stand by for the purpose of flushing the latrine. These conveniences are usually placed over large barrels, which are periodically emptied. Cleanliness in this matter is specially enjoined by the Moslem religion, and is usually pursued.

In the cities of European Turkey modern systems of drainage are being generally adopted. The natives of New Zealand are said to provide regular privies for every two or three houses; while those of the Marquesas Islands follow the primitive and wholesome custom of digging a hole in the earth or sand in order to bury their ordure. It is almost inconceivable that no privies existed in Madrid prior to 1760, the filth being thrown out of the windows after night-fall. Edinburgh was long notorious for this disgusting practice. In ancient Rome there were public latrines, but no private conveniences. Privies in houses were adopted in Paris in 1513, and in London toward the end of that century.

TRAPS AND VENTS.

W. N. McKENNA & Co., plumbers and contractors, 60 Anderson street, Boston, have finished the plumbing of the Massachusetts Building at the World's Fair. The Sanitas fixtures were exclusively used.

AS AN INDICATION of the prosperous condition of the plumbing trade in Chicago and vicinity, J. B. Clow & Son, manufacturers and dealers in plumbers' supplies, Lake and Franklin streets, state that their city trade for the present month has been twice that of the corresponding month of last year.

THE MICHIGAN STATE ASSOCIATION OF MASTER PLUMBERS, after several preliminary meetings, were organized March 16, at Detroit, Mich., with the following officers: President, Thomas Meathe, Detroit; vice-president, S. J. Wirtz, Jackson; secretary, F. C. Bennett, Lansing; treasurer, J. A. Wheeler, Kalamazoo. Executive Committee: J. H. Crumley, Detroit; W. C. Weatherby, Grand Rapids, and John Bradley, Port Huron. The next meeting of the association was appointed for May 5.

HERMAN C. STIFEL, St. Louis, and Francis J. Torrance and Oscar F. Grant, Allegheny, Pa., have secured a patent on an improvement in bathtubs, the principal feature of which is means for keeping the inner surface of the walls clean without the necessity of scrubbing. The invention consists in the combination with the bathtub of a hollow metallic rim for use as a water conduit, taking its supply from the hot and cold water supply adjacent to the tub and conveying the water to the interior through small jet openings against the sides.

THOMAS KELLY & BROTHERS, 123 Franklin street, Chicago, Ill., issue an 1893 illustrated catalogue of permanent plumbing goods which they manufacture and upon which they own the patents. The publication of 50 pages contains illustrations of a large variety of water closets, including the Kelly self-acting wash out: the Kelly self-acting frost proof after flush: the Kelly syphon: Kelly self-acting, &c. There is also a varied assortment of special articles, such as anti-freezing hopper cocks, lock pulls, poor water supply remedy, water cushions and many other goods. At the close attention is directed to the Kelly lavatory and sanitary syphon wash basin, the advantages of which are pointed out.

E. ASPINALL, 98 and 100 Beekman street, New York, has been made the sole agent in this country for the sale of lavatory basins made by T. W. Twyford, Cliffe Vale Pottery, Hanley, England, said to be one of the largest in Great Britain. The basins are made in 12 styles, aggregating 28 sizes, any of which can be furnished in white or marble finish. These goods are adapted to a variety of locations, whether in corners or flat against a wall, while the fronts are of various shapes, affording a good assortment to select from.

THE PLUMBERS' SUPPLY STORE of Dixon & Ballou, at Buffalo, N. Y., was destroyed by fire March 10. The enterprising firm have already rented another store and ordered a new stock of goods. They will be ready to continue business in a few days.

New York's Water Supply.

Governor Flower has signed a bill empowering the Commissioner of Public Works of New York city to purchase such lands in the Croton watershed as he thinks proper to secure the purity of the city's water supply. By the terms of the bill the sum of $1,500,000 is to be applied to this purpose at the rate of $500,000 yearly for three years. The Governor, in signing the bill, filed a memorandum stating that, while there is no practical objection to the enactment, he would recommend that if there is any doubt whatever as to the sufficiency of the measure for the sanitary protection of the watershed, "the Legislature should not hesitate to remove the doubt by the enactment of a supplementary measure suitably comprehensive in its terms." The Croton Aqueduct Commission filed a memorial recommending the rescinding of the three yearly clause in order that no delay may be incurred on account of limited funds, while the New York Academy of Medicine recommended that the work be confided to a commission of sanitary experts, with plenary powers.

A Washington dispatch says the President wishes it to be known that in the appointment of consuls, particularly those to places in South America and Central America, he will be guided largely by the adaptability of candidates for business. These consuls are to be persons of experience in all trade matters, so that they can readily recognize whether a port is capable of becoming a good market for American goods.

There is a strong probability that the Argentine railways enjoying the national guarantee will eventually revert to the Government on account of their increasing indebtedness. The Minister of the Interior states that the total advances to the end of their concession will approach $100,000,000. Therefore, to enforce its claim, the only method would seem to be to take possession of the property.

While the consumption in the United States of such articles as sugar, beer and tobacco has increased with enormous rapidity of late years, there appears to be comparatively little gain in the demand for wheat, tea and coffee.

ROOFING AND CORNICE.

Laying Zinc Roofs Abroad.

The roofing trade in this country have always felt a great deal of interest in the use of zinc for the covering of buildings, but no appreciable advance has been made in the application of the material. We often receive letters from roofers asking how it should be applied and why it has not come into use here to some extent. We would like to have the subject of zinc roofs discussed in the columns of *The Metal Worker*, and we think there must be many of our readers who have had early experience in the use of the roof abroad and could tell us of the methods there followed in laying this metal. We print below an interesting account of one style of laying zinc roof as furnished by J. B. Marold, Saquache, Col., who furnishes some particulars of the construction, as well as illustrations of the method of applying the metal. In the early part of his letter he discusses the question of applying the material in this country.

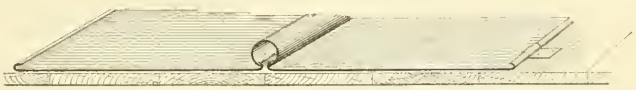


Fig. 1.—Method of Laying Zinc on Small Roofs.

Fig. 2.—Roof Patten.

Fig. 5.—Perspective View of Sheets Laid with Patten.

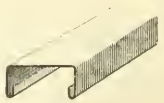

Fig. 4.—Cap with Lock.

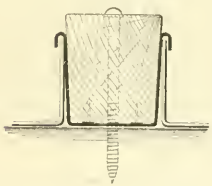

Fig. 3.—Patten with Cleats.

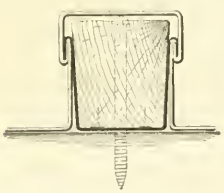

Fig. 6.—Section through Patten and Cap.

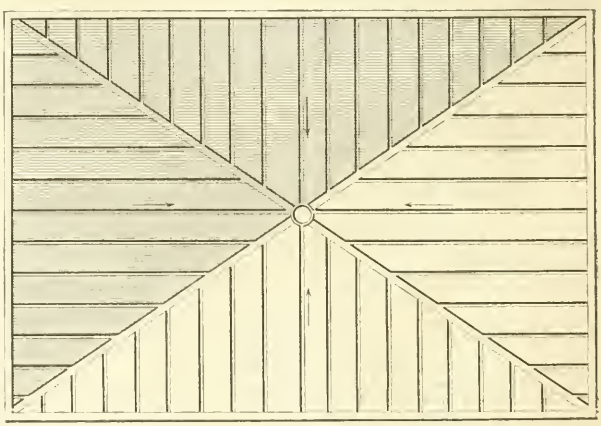

Fig. 7.—Roof Draining to Center.

LAYING ZINC ROOFS ABROAD.

He writes: "Concerning zinc roofs, I believe that the American climate, with its great variation of heat and cold and sudden changes, moves the metal more than the more temperate and even climate of Europe. Even there, however, I noticed that zinc had to be treated differently from tin. Standing seams, for instance, would not hold one year. In order to get space for contraction and expansion, we employed different methods, but in no case did we put the sheets together in long rolls, but laid each one down separately. The cross seams were located and soldered and fastened down with cleats. On very small roofs it is customary to make a wide lock on the sheet lengthwise, fasten it down with cleats and draw a cap, like an open round pipe over the adjoining edges. This style of roofing is shown in Fig. 1.

"The most common way, however, and one that always gave good results, was with the use of pattens or strips, which are screwed on to the roof between the sheets. Fig. 2 is a sectional view through one of these strips. On the bottom of the patten a strip of tin 5¼ inches long and about 2 inches wide was nailed, as shown in Fig. 3, the strips serving the double purpose of holding the sheets and securing the cap that fitted over the top of the patten. These pattens were generally 16 feet long,

2 inches high, 1¼ inches wide at the bottom and 1½ inches wide on the top. When the sheets were laid and the patten screwed on the sheeting, the strip of tin referred to was bent about the patten and over the edges of the tin, as shown in Fig. 3, holding it securely down, but leaving room, however, for the moving and working of the metal. After the roof was laid no little annoyance and possible damage by the dripping in the interior of the structure. This arises from the fact that warm air holds in suspension more moisture than cold air. The warm air of the interior of the building coming in contact with the cold corrugated iron of the roof is chilled, and, as a result, deposits a portion of the moisture on the under side of the iron. When the quantity is sufficient this will drip, resulting in not only great inconvenience, but serious loss, depending, of course, upon the kind of work that is being carried on in the building. With a view to overcoming this difficulty, the Berlin Iron Bridge Company of East Berlin, Conn., have introduced a form of roof construction which is manufactured under patents controlled by them. Upon the purlins of the roof trusses is first tightly stretched galvanized iron wire netting. Upon this, as a foundation, are placed two layers of asbestos paper, well lapped and smoothly laid, the edges of each sheet overlapping its neighbor about three inches, while each layer protects the joints of the next layer. Above this, in turn, and laid in exactly the same manner, are two layers of tarred paper, with tar between, or asphalt or Neponset paper, as may be most convenient, put on with broken joints, smooth and flat. On top of this composition is laid the corrugated iron in the usual way. We understand that roofs put on in this manner are guaranteed not to condense moisture on the under side. These roofs, we are told, have now been in use for about five years, through different seasons, and in no case has there been any signs of condensing moisture on the under side. In Fig. 1 is shown a plan view of a portion of a roof covered as above described, while in Fig. 2 is represented a section. The different materials of which the roof is composed are clearly indicated by the fine lettering at the right. In Fig. 3 is shown one of the buildings covered by the company with this anti-condensation corrugated iron roof, it being a foundry building for S. F. Hodge & Co., Detroit, Mich. A number of structures have recently been covered by the Berlin Iron Bridge Company with their patent roof, among the number being a dynamo room for the Elmira Illuminating Company, Elmira, N. Y.; boiler house for Cheney Bros., South Manchester, Conn.; dynamo rooms for the U. S. Electric Company, at Washington, D. C., and for the Pawtucket Gas Company, at Pawtucket, R. I., as well as an engine room for the Narragansett Electric Company, at Providence, R. I.

Anti-Condensation Corrugated-Iron Roofs.

It is very well known that when corrugated iron is exposed directly as a roof covering for buildings, for whatever purpose they may be employed, moisture is apt to condense on the under side during the colder months of the year, and cause

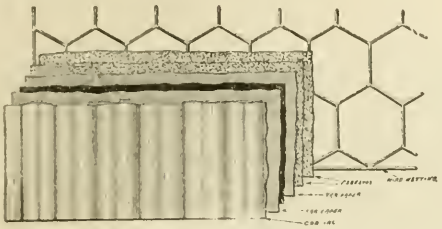

Fig. 1.—Plan View of a Portion of Roof.

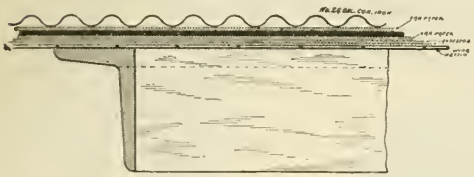

Fig. 2.—Cross Section through Roof.

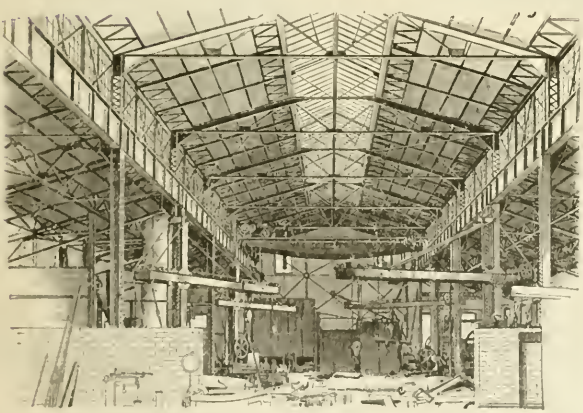

Fig 3.—Interior of Foundry Covered with Anti-Condensation Corrugated-Iron Roof.

ANTI-CONDENSATION CORRUGATED-IRON ROOFS.

a machine-made zinc cap, Fig. 4, was drawn over the pattens, as shown in Fig. 5. Fig. 6 is a sectional view through patten, showing the way the zinc cap was locked down by the cleats.

"I saw a curious variation of this style of roof on a royal castle, in which, instead of raised pattens, there were grooves sunk in the sheeting. The valley rafters also pitched toward the center of the roof, where there was a large receiver, from whence the water was carried to the sewer. A plan view of this roof is shown in Fig. 7."

FLASHINGS.

The Columbia Roofing Company of Canton, Ohio, favor us with a catalogue relating to the line of goods which they are prepared to furnish the trade. This roofing is said to be made of the best quality of steel, and is thoroughly plated on both sides. It is put up in rolls 50 feet long by 26¾ inches wide, and will lay one square of surface. Every sheet is inspected before painting, and the manufacturers state that the utmost care is taken to see that all sheets are free from holes, splits, or other defects. A list of the tools which the company furnish for use in applying the roofing is given, together with suggestions of general interest to the trade. Illustrations are presented of V-crimped roofing, pressed standing seam roofing, beaded iron siding and ceiling, corrugated iron, imperial pressed steel brick siding made of sheet steel and painted, patent rock face brick siding and patent slip joint eave trough.

The Caldwell & Peterson Mfg. Company of Wheeling, W. Va., issue an illustrated pamphlet descriptive of their patent metal ceilings, which are recommended for their simplicity of construction and economy of erection. Each panel is composed of a metal sheet, mounted complete, on a tongue and grooved wood frame. The wood frames fit into the adjoining panels as flooring boards fit into each other. The joined frames are then covered with metal moldings and rosettes, which, with nails, &c., are furnished by the company, so that a complete ceiling can be shipped without delay, ready for placing. The panels and fittings are made in various patterns, shown in the

circular. Attention is also called to the metal wainscoting, steel roofing and steel lath manufactured by the concern.

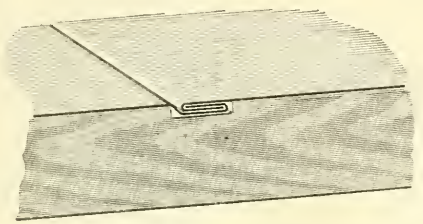
ROBLEY & BRUNDAGE, 142 Chambers street, New York, are agents for the Prentice patent metallic hip shingle, made by the Metallic Hip Shingle Company of Toledo, Ohio. A circular is issued by the agents illustrating the appearance and application of the metallic hip shingle, pointing out its merits and giving a number of testimonial letters.

AT THE ANNUAL MEETING of the Metallic Roofing Company of Canada, Limited, E. Samuel was re elected president, A. D. Benjamin, vice-president, and J. O. Thorn, secretary. The company are making arrangements to start a branch factory in Montreal.

Improved Seam for Tin Roofing.

We have received from John S. Brooks, 235 Fifth avenue, Brooklyn, N. Y., the following account of a new method which he has devised of laying cross seams:

The manner of laying flat seam roofing shown by the sketch given appears to answer two important purposes. It will facilitate soldering, as the solder first enters the seam in a downward course



Improved Seam for Tin Roofing.

to enable it to penetrate into the folds, and it leaves the surface of the roof flat on its upper side and solid on the roof boards. As the seam consists of four layers of metal, quite a hollow space is left near it on its upper side when put on in the usual way, and, so far at least as the cross seams are concerned, this ends in letting the tin sink to the roof boards and leaving a ridge at every cross seam to hold water. By an experiment it was found that a large goblet of water emptied on a roof slowly only reached the third course of tin below it, being held in the depressions mentioned. It is only a simple piece of work, coating next to nothing to run a tool similar to a joiner's grooving plane across the roof. After one cut is made that can be used as a guide for a gauge to run in to form all of the other grooves, and the plane should be so made that it will also level off any inequalities in the thickness of the roof boards at the same time. It is not necessary to sink the up and down seams. Observation shows that nearly all the leaks in tin roofs occur at the cross seams. They are more difficult to solder and are the only ones that hold back the water after a rain or in the damp weather, when heavy dew settles on them. If any one will look down on a tin roof that has been used, as all are at times, to walk upon, they will see at once the depressions mentioned, and find them holding water if rainy, or filled with dust when it is dry. The operation of hammering down the seams beds the tin into this groove, and if paper is used under the tin it will not interfere in the least with the work. Roofing leats should be used with this method.

Immigration Resumed.

The enforced suspension of immigration from Europe, which followed Treasury orders imposing a rigorous inspection at quarantine, is no longer operative. For awhile, and perhaps until the spring has well advanced, there is not likely to be any necessity for excluding immigrants of the better class, as a measure to bar out infectious disease. Cholera is known to be prevalent in parts of Russia and there are indications of its presence at points in other parts of Europe contiguous to regions whence much of our immigration is derived. Therefore all quarantine officials, whether at home or on foreign stations, will be on the alert to observe the first threatening symptoms and take measures to arrest the danger. These facts being understood, it is not surprising that the usual spring immigration from the Old World has already commenced in full volume. The immigrant landing at Ellis Island, deserted all winter, is again thronged with new arrivals and the customary troops of persons of foreign mien, encumbered with worldly possessions, are seen *in transitu* for their destination, usually in the far West. Indeed, it is evident that the temporary check to this movement only served to dam the current, which, being released, now moves forward with renewed impetus. We may reasonably anticipate, therefore, the addition of something like another half a million of people from over the seas before the expiration of the year. The peculiar political, social and industrial conditions of Europe at the present time, contrasted with the comparative affluence of the United States, the prosperity of trade, abundance of food and exemption from war alarms, all contribute to excite a feeling of unrest that can be satisfied only when a ticket is bought guaranteeing transportation to that far-famed elysium beyond the setting sun.

The question to be immediately considered by the national and State quarantine authorities with reference to this subject is the necessity of adopting such measures as shall secure uniform regulations along the entire coast and harmony of action in enforcing these regulations during the coming summer. To this end an important conference was held at Washington during the past week, in which the health officers and port physicians of all the seaboard States participated. The conference was called by the Secretary of the Treasury at the solicitation of Supervising Surgeon-General Wyman of the Marine Hospital Service, who had framed a system of rules applicable to all the ports, to serve as a basis for deliberation. The regulations define the equipment of stations, state what vessels should be inspected, how they shall be treated if diseases are found aboard, the mode of treatment of specific diseases, the proper mode of disinfection, &c. Special rules are made with reference to quarantine for cholera and yellow fever.

In the form finally agreed upon, these regulations will be sanctioned and promulgated by the Treasury Department. At the same time, American consuls abroad will exercise due vigilance and care that every needed precaution is taken by port officials and steamship companies to prevent the spread of infectious disease. Every vessel must be fumigated, every emigrant examined, and no bill of health given until all requirements are literally complied with. Hamburg suffered severely last season from neglect of sanitary precautions, likewise the steamship companies, which were driven from the trade as a consequence, so that the strongest motives of self-interest prompt to fidelity in the performance of duty on the part of all concerned. Thus with a double line of defense, as above defined—port officers and consuls co-operating with steamship companies—we may entertain a reasonable hope that the danger that threatened last summer will be warded off no less successfully should pestilence again menace our shores. As amended by the Secretary of the Treasury, steam vessels from a suspected or infected port may be allowed to enter after fumigation at quarantine and five days' subsequent detention.

The Western Pipe Consolidation.

The consolidation of the Western and Southern cast-iron pipe foundries, to which reference was made earlier in the year, is getting into shape. The companies represented at a meeting at Buffalo last week were Addyston Pipe & Steel Company, Addyston, Ohio; South Pittsburgh, Tenn., Pipe Works; Shickle, Harrison & Howard Company, St. Louis; Howard-Harrison Iron Company, Bessemer, Ala.; Lake Shore Foundry Company, Cleveland, Ohio; Radford Pipe & Foundry Company, two plants, one at Radford, Va., and the other at Anniston, Ala.; Dennis Long Company, Louisville; Chattanooga Foundry & Pipe Company, Chattanooga & Ohio Pipe Company, Columbus, Ohio.

There are not included, therefore, a number of small concerns, like the Hercules Foundry Company, Pell City, Ala.; New Birmingham Pipe Works, New Birmingham, Ala.; Rusk Pipe Works, Rusk, Texas; Cleveland Pipe Works Company, New Philadelphia, Pa.; Massac Iron Company, Metropolis, Ill.; Detroit Pipe & Foundry Company, Detroit; West Superior Iron & Steel Company, West Superior, Wis., and the South St. Louis Foundry at St. Louis.

It is proposed to call the consolidated company the American Pipe & Foundry Company, with headquarters at Chicago. Gen. Samuel Thomas of the Union Trust Building, New York, is expected to place a part of the new capital with Eastern investors.

One of the causes that has led to long delay has been the contest for the presidency of the new company. As a compromise between the different parties, O. C. Barber of Chicago will probably be chosen.

The great double track tunnel in process of excavation through the Palisades near Weehawken in New Jersey is making rapid progress and will be completed before the end of December. It will be one mile in length, and extends from the meadows to the tracks of the New York, Susquehanna & Western Railroad at Little Ferry Station, in whose interests the work is supposed to be. At the eastern mouth of the tunnel, piers, coal sheds and freight warehouses will be erected the coming summer.

Under the law of 1891, authorizing the President to set apart as a reservation any public land covered with trees, about 12,000,000 acres have been recovered from the woodman's axe. The principal tracts are in Utah, New Mexico, Colorado, Minnesota, California, Oregon and Washington.

"The Metal Worker" Competition in Skylight Pattern Cutting.

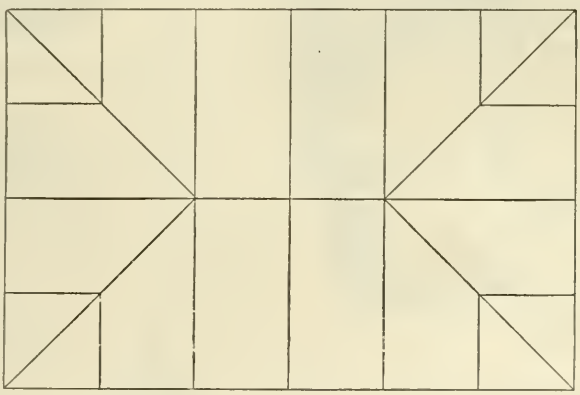
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight, and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desired pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

COPPERSMITHING.

ART OF COPPERSMITHING.

XLI.*

DOME AND PAN COPPERS.

Dome and pan coppers are a combination of the other two coppers we have steam generated in the copper into the liquor which may have been placed in the pan to be heated. It will be seen that the pan bottom is made separate, and when formed ready the inner edge is fitted to the sides, with the edge of the dome crown (except when the dome is in one copper. At the upper end of the inlet pipes and on the inside of the pan bottom is bolted a screw valve, Fig. 462, which is secured to its place by the same bolts that hold the pipe flange to the pan bottom. When the pan bottom and crown (if the dome is made in pieces) have been

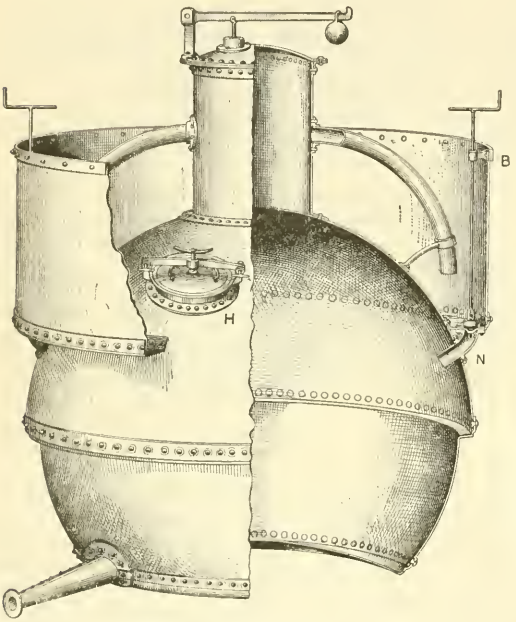


Fig. 461.—*Dome and Pan Copper.*

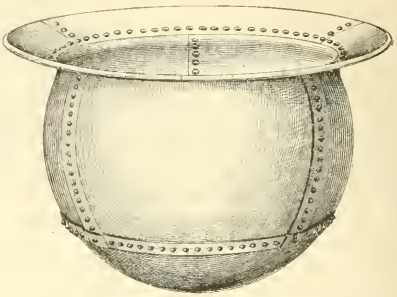

Fig. 463.—*Broad-Brim Tallow Copper.*

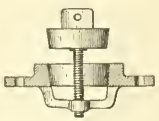

Fig. 462.—*Screw Valve.*

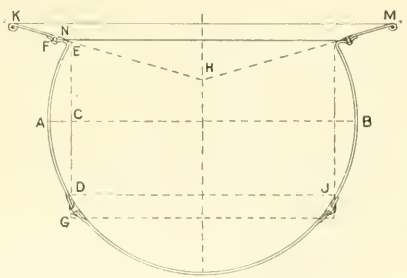

Fig. 464.—*Section through Broad-Brim Tallow Copper.*

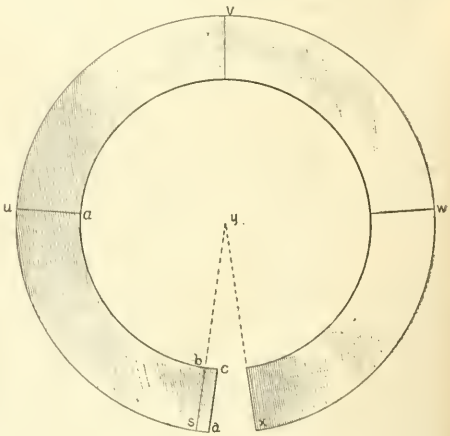

Fig. 465.—*Pattern of Brim.*

been treating of, combined in one apparatus with some few additions, such as the valves at the top of the chimney and the two side pipes to convey the overflow into the pan should the liquor in the copper tend to boil over ; also to convey the piece, when the pan would be worked on the dome as shown in Fig. 461), and then all three are riveted secure, and the rivets scrubbed up so that the heads are all smooth and even with the inner side. The inlet pipes are made of a suitable size, as in N, and connected by flanges with the pan bottom and the side of the worked in, the manhole H, Fig. 461, and the inlet pipes also completed, then the sides of the pan may be put up into position and the rivets worked in. The screw valves are now applied with a rod and T-handle, with which to open and close them, the rod being held in position by a bracket, B, bolted to the side of the pan.

*Copyrighted 1880, by JOHN FULLER, Sr.

Any good workman who has made a large open or dome copper should be competent, after studying the preceding pages and the accompanying illustrations, to build a dome and pan successfully. I shall therefore let the directions given for the building of the other two styles suffice for that of a dome and pan, and thus avoid repetition as much as possible.

TALLOW COPPERS.

In Fig. 463 is shown a tallow copper. These vessels were made for and used by tallow chandlers, whose principal use for them at one time was in manufacturing tallow candles. Tallow coppers are an extra good job, because of the greater care necessary to make them sound—that is to say, perfectly tight and not liable to leak. These coppers were at one time in great demand, when all England burned candles much more so than now. But there is yet an occasional demand for one, because tallow is still used for many other purposes besides that of making candles, and the shape of this copper is better adapted for the use of rendering out tallow than any other, as the curve or spherical shape of the sides tend to throw the fat that boils up the sides toward the center, which partly accounts for its peculiar shape, as compared with coppers for some other purposes. This copper has a wide brim, so that any slopping or drainings may be conveyed back into the copper by it. They are made sometimes with narrow brims, in which case the broad brim is substituted by one made of lead, covering the whole of the brick work on its top surface about the brim, and turning down over it on the inside of the copper from 2 to 3 inches, which, in some cases, is preferable, because, then, none of the tallow can penetrate the brick work from the top.

Let us make one of these broad-brimmed tallow coppers, and let the sides be made from a sheet of, say, 35-pound plate, or about $\frac{1}{8}$ inch in thickness, to hold 200 gallons, and let its sides be in three pieces and the bottom in one. It will be noticed that this vessel, Fig. 463, is spherical in form, the body being made up of the middle zone and the bottom segment, the other or top segment being absent to form the brim or copper mouth. Now, the first thing we must do is to find the size of a vessel of this shape that will hold 200 gallons, which we will now proceed to do as follows: It is well known that a spherical inch is represented by 0.5236, but the copper is a sphere with a segment cut off equal in hight to one quarter of the diameter of the sphere (see Fig. 464), and the value of this segment cut off is 0 08181; therefore $0.5236 - 0.08181 = 0.4417$. Now there are 277.274 inches in a gallon (English measure), therefore $277.274 \times 200 = 55,454.80$ cubic inches, and $\frac{55,454.80}{0.4417} = 125,548$; when, extracting the cube root of 125,548, we get 50 inches as the diameter A B of the middle zone of the copper when ready for the bottom. If Fig. 464 be drawn to a scale of $\frac{1}{4}$ inch to a foot, it will be found that from C to B is 47 inches, from D to E is 25, from F to E is 4 inches, and from D to G 3 inches. Adding these last three dimensions together, we have $25 + 4 + 3 = 32$ inches for the depth of the sides before working, and the diameter C B 47 inches, when $47 \times 3\ 1416 = 147.6552$, and 147.6552 divided by 0.03, the number of sides to be used, we have 49 2184, or 49¼ inches. To this we add 2 inches to each piece for seams, when we get 51¼ inches for the length of each side, including edges, and 32 inches deep, including brim and lap for the bottom seam. Now we find the size the disk should be for the bottom before hollowing as follows: It was stated in a former chapter that the surface of a sphere is equal to its circumscribed cylinder, and therefore the surface of any segment of a sphere is equal to the diameter of the sphere multiplied by the hight of the segment, multiplied by 3.1416; or the surface of a sphere is equal to four disks, whose diameter is equal to the diameter of the sphere. From which we get $50 \times 12.5 \times 4 = 2500$, and extracting the square root we get 50 inches for the diameter of the disk to form the bottom before hollowing, or $\sqrt{50 \times 12.5 \times 4} = 50$. Now we have the sides and bottom, and require the broad brim, which is obtained as follows: The brim when completed with a ¾-inch wire in the outer edge should measure 10 inches or thereabouts from E to K, Fig 464. Now the wiring edge at K will take 1½ inches, and will reach and lap at N 2 inches, which will make the brim before working 10½ inches wide. Then the diameter of the brim from K to M when complete before wiring is 66 inches, and forms a frustrum of a cone, the slant hight of which is H M, or 34 5; that is, *x y*, Fig. 465. With the radius *y x* from *y* as center describe the circle *x w v u s*, making the distance around it from *x* to *s* equal to the circumference of a circle whose diameter is K M, or 66 inches. Now $66 \times 3.1416 = 207.24$ and $69 \times 3.1416 = 216.66$ and $216.66 - 207\ 24 = 9.42$, or 9¼ inches nearly; that is to say, the segment *s y x* from *s* to *x*, which would be taken out, is equal to 9¼ inches nearly. The brim may be put on in any number of pieces. In this case let there be four; then *s u a b* is one section of the brim bare: adding 2 inches on for riveting edge, the pattern is complete and will measure from *u* to *d* 56.16, and from *a* to *c* 38.09, and from *c* to *d* 10.5 inches. Here we have all the patterns and will now begin to put them in shape: First, the bottom, by taking it to a hollowing tub, and with suitable mauls sink it in the tub until it is hollowed enough; that is, until it measures across it 46 inches. Then mark the rivet holes for about No. 1 or No. 2 wrought copper rivets, and space the holes so that the edges of the rivet heads are about ¼ inch apart. The sides are next in order. These will be put together with No. 3 or 4 rivets, and the heads about ⅝ inch apart and reaching to within ¼ inch of the lap edge. When the sides have been punched bend them into shape and put in a few temporary rivets; take a racer and divide the depth into three spaces and proceed to raze in both ends; the bottom end right out to the end, the top end to within ¼ inches, making the lower end fit into the bottom about 3½ inches, and drawing the top end out until it measures 43 inches at 4 inches from the end, when the brim is thrown back for the additional wide brim. While the two ends are being worked in the sides are put on the tub at the end of each course, and hollowed out to complete the spherical curve of the body. Now we form the brim by putting the four pieces together and wiring the edge with a ¾-inch iron ring. The workmen may now select which is more convenient to him, and first put on the brim or the bottom. If the brim is first put on, carefully scrub the rivets and make the surface smooth about the rivet heads, and work the seam edge carefully down close, then the same with the bottom. It is usual to rub the seam well with white lead and oil on the inside after the job is finished.

NOTE.—In this connection some piece work prices for coppersmiths' work paid in London will be of interest:

Brewing coppers, 3½ cents per pound for men; one-half the price for boys.

Niches for planishing general, 2 cents for men; one-half the price for boys.

Four-inch worms, 4 cents per pound for man and boy.

Retorts, 6 cents per pound for man and boy.

Stills, 3½ cents per pound, metal as well.

Middle pieces, 4 cents per pound for brazed seams.

Four-inch tee-pieces, $1 each for men; 50 cents for boys.

Three-inch tee-pieces, 75 cents each for men; 37½ cents for boys.

Four-inch bend complete, 83 cents each for men; 41½ cents for boys.

Three and one-half-inch bend complete, 64 cents each for men; 32 cents for boys.

Three-inch bend complete, 50 cents each for men, 25 cents for boys.

Two-inch bend complete, 37½ cents each for men, 18 cents for boys.

Worms, when two men work at them, 8 cents; when a man and boy work them, 6 cents.

The time usually consumed putting up sides into bottom of a 300-barrel copper by two men inside and three outside, two and one-half days. Punching holes, in bout, three men inside and two outside, one and one-half days each.

Setting-to 195 holes, two men one day. Setting-to 20 holes in seam and working in 20 No. 2 nails, with one man inside and two outside, three hours.

Working one seam of 20 nails, three men, one day. Working one bout of 15 nails, No. 1, three men, one day.

Time consumed taking off old bottom from a dyer's copper and putting on new one, the new bottom weighing 140 pounds, 38 inches in diameter and 8 inches deep. Cutting out old bottom and annealing sides and planishing, ten hours. Planishing new bottom, seven hours. Putting up block, punching holes, bolting together and working in 40 No. 4 nails, nine hours. Scrubbing up new bottom, eight hours. Total time for job, three days four hours.

Andrew Morton, 191 East Third street, New York, is making a standard cork bath mat, which is offered as a superior article for this purpose. The dimensions are about 18 x 27 inches outside and nearly 1 inch high. Cork blocks 3 inches square are strung flat on nickel plated steel bars and then mounted in a solid hardwood frame. All screws and metal attachments are plated to prevent corrosion. An advantage claimed is the warm, smooth velvety surface, obviating the risk of cold or chills after the bath, always maintaining a uniform temperature. E. Aspinall, 98–100 Beekman street, this city, has these goods on sale.

The first theater in Europe to use the electric iron curtain as a safeguard from fire is the Comédie Francaise, in Paris. This curtain was put up by the Edison Electric Light Company, assisted by the chief machinist of the theater, and has now been in successful operation for some weeks. The curtain is hung by four steel wire ropes, which run over pulleys driven by an electric motor. The total weight of the curtain is about 880 pounds, and is balanced by a counterweight held by a cord. The speed at which the wheels run is 1800 revolutions a minute, the motor being of 2 horse-power. The curtain can be lowered or raised at the maximum speed of 5 feet per second, the minimum speed being 2½ feet per second.

The London *Plumber and Decorator* gives the following recipes for two cements, which have been found of considerable value in calking iron pipes: 1. Two parts of ordinary well-dried powdered loam and one part of borax are kneaded with sufficient water to a smooth dough, which must at once be applied to the joints. After exposure to heat the cement adheres even to smooth surfaces so firmly that it can only be removed with a chisel. 2. Mix 430 parts by weight of white lead, 520 parts of powdered slate, 5 parts of chopped hemp and 45 parts of linseed oil. The two powders and the hemp, cut into lengths of ¼ inch, are mixed intimately, the linseed oil gradually added, and the mass is then kneaded until it has attained a uniform consistency.

The daily product of pins in Birmingham, England, alone, is stated to be 37,000,000. And still the question as to what becomes of all the pins is an unsolved mystery.

George I. Holdship, Allegheny, Pa., is the patentee of an apparatus for beading and curving sheet-metal machines. The object is to provide a machine by which both these steps may be performed at one operation.

Prize Competitions

$25.00.

IN ORDER to obtain information which will be of practical service to our readers we hereby announce

Prize Competition No. 17.

SUBJECT:

How Merchants Should Treat Traveling Salesmen.

In view of the fact that traveling salesmen occupy an exceedingly important place in securing orders, the manner in which they should be treated is a question deserving the careful consideration of the trade. This competition is intended to call out suggestions on this subject, and may naturally touch upon such points as the following:

The courtesy which should be shown to traveling salesmen;

The extent to which it is advisable for the merchant to give attention to all salesmen offering goods in his line;

The disadvantages of discourtesy;

The information which may be received by the merchant;

Legitimate methods of securing the lowest prices;

The advisability of purchasing from comparatively few or from a larger number of travelers;

To what extent the merchant should ask quotations on each article or leave the price to the salesman;

The advantages and disadvantages of holding orders for favorite travelers;

Treatment of travelers' broken promises and misrepresentation;

Practices justifying a discontinuance of buying from them;

The faults of merchants in the treatment of travelers;

The faults of travelers in the treatment of merchants.

This competition will remain open until April 15, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than April 15, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.

Prize Competition No. 17.

The committee to whom the contributions in Prize Competition No. 3 were referred have awarded the prizes as follows:

First Prize to W. T. WARSOP, Fairport, N. Y.

Second Prize to H. C. WISEMAN, Springfield, Ohio.

Third Prize to G. B. KORBETT, New York.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 14. Closing March 25.

Suggestions Regarding the Sale of Spring and Summer Goods.

No. 15. Closing April 1.

Suggestions in Regard to the Sale of Athletic and Sporting Goods.

No. 16. Closing April 8.

Three or More Rules to be Observed in Buying.

No. 17. Closing April 15.

How Merchants Should Treat Traveling Salesmen.

Another subject will be announced in our next issue.

An exchange says: A good plan for preserving tools from rusting is the simple preparation employed by Professor Olmstead of Yale College for the preservation of scientific apparatus, and which he long ago published for the general good, declining to have it patented. It is made by the slow melting together of six or eight parts of lard to one of rosin, stirring till cool. This remains semi fluid, ready for use, the rosin preventing rancidity and supplying an air-tight film. Rubbed on a bright surface ever so thinly, it protects and preserves the polish effectually, and it can be wiped off nearly clean, if ever desired, as from a knife blade; or it may be thinned with coal oil and benzine.

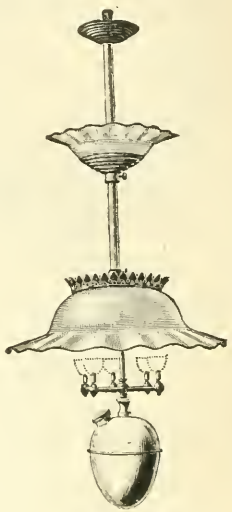
A French inventor has attached a tiny incandescent lamp to an ordinary pencil for use by reporters and others having to take notes at night. The battery is carried in the pocket, the wires passing down the sleeve.

The largest steam hammer in France has been erected at the works of Marrel Frères, Rives de-Gier. It is of 100 tons and has a fall of 19 feet. The anvil weighs 760 tons, the face being in one piece of 125 tons. The hammer is served by a traveling crane capable of lifting 120 tons, and two radiating cranes, one of which can lift as much as 180 tons.

The largest anvil in the world is supposed to be one now in use in the Royal Arsenal at Woolwich, England. It weighs 60 tons. The anvil block upon which it rests weighs 103 tons. Altogether, 600 tons of iron were used in the anvil, the block and the foundation work.

The Boston Gas Lamp.

In the accompanying illustration we present a general view of what is known as the Boston Gas Lamp, which is being offered the trade by G. H. Gregory of Boston, Mass. The illustration so clearly shows the general arrangement of the device that very little description is necessary. The depending bulb below the burners is a reservoir or receiver filled with kerosene or crystallized naphthaline. The fuel which is supplied to the burners may be either city gas or natural gas, as most convenient. The gas passes down the pipe to the receiver, from which is generated a rich gas which, mixing with the inflowing vapor and passing to the burners, produces a flame of high candle power. The manufacturer claims that



The Boston Gas Lamp.

this arrangement gives a very bright light at small expense and that the illuminating power of the gas used in the lamp is increased over 70 per cent.

The Pacific Northwest, lying north of California, promises commercial importance as a fruit-growing country. Prune culture is especially remunerative. East of the Cascades and west of the Rockies lies an immense region, known as the Inland Empire, mostly rolling upland, but portions produce choice fruit, as at the Dalles, close to the Cascades, at Walla Walla and in the Palouse. A very interesting fact in connection with that region is that the river cañons of the Columbia and Snake rivers and their tributaries, all of which have cut down through alluvial uplands, sometimes thousands of feet, produce fruits not grown in the coast valleys and not possible on the adjoining uplands. There is very little of these river lands, but where some stream or cañon debouches there may be a sandy loam spot where fruits can grow, or on the lower benches of the hills. The Columbia comes south from British Columbia for 300 miles, to its junction with Snake River, which rises in the mountains of Utah and Idaho; through all their course, draining 10° of latitude, these cañons and river shores produce all the fruits of the region and many grown in California.

THE RETAIL STORE.

Standard Hardware Lists.*

The second edition of *The Iron Age* Standard Hardware Lists, revised and enlarged, has been published and contains a number of lists not before issued in this form. The lists are intended to be cut out and inserted in price books and for this purpose are printed on thin and tough paper of the best quality, and on only one side of the paper. The pamphlet includes the following lists:

Auger Bits.
Augers.
Bells, Hand.
Belting, Leather and Rubber.
Boilers, Round.
Bolts, Carriage, Common.
Bolts, Carriage, Norway Iron.
Bolts, Carriage, Philadelphia Pattern.
Bolts, Machine.
Bolts, Plow.
Bolts, Stove.
Bolts, Tire.
Bowls, Scotch and Yankee.
Brads.
Butts, Brass.
Butts, Cast.
Butts, Wrought.
Cartridges.
Casters.
Chains, German.
Chain, Jack.
Chain, Safety.
Chisels.
Cocks, Brass.
Compasses.
Dividers, Wing.
Files.
Freezers, Ice Cream.
Gimlets.
Glass, Window.
Gouges.
Griddles.
Hasps and Staples.
Hinges, Strap and T.
Hoes, Eye.
Hoes, Field, Mortar, &c.
Hoes, Planters' and Cotton.
Hollow Ware, Stove.
Hooks, Awning.
Hooks, S.
Hooks and Staples.
Iron List, Eastern.
Iron List, Western.
Kettles, Brass.
Kettles, Cast Iron.
Kettles, Maslin.
Knives, Drawing.
Mattocks.
Mowers, Lawn.
Nail Card, Cut.
Nail Card, Wire.
Nails, Horseshoe.
Nails, Miscellaneous.
Nails, Wire, in Packages.
Nuts.
Oilers, Machine.
Paper, Sand and Emery.
Picks.
Pipe, Wrought Iron.
Plane Irons.
Points, Glaziers', &c.
Pots, Cast Iron.
Pots, Glue.
Rakes, Garden.
Rasps, Horse, &c.
Rings, Trap Door.
Rivets.
Rivets and Burrs.
Sauce Pans.
Screw Drivers.
Screws, Brass and Bronze.
Screws, Iron Wood.
Screws, Coach or Lag.
Shells.
Slicks, Carpenters'
Spiders.
Staples.
Squares, Iron and Steel.
Stocks and Dies.
Tacks.
Tacks, Carpet.
Trimmers, Bent and Straight.
Vises, Solid Box.
Washers.
Wire.
Wire Goods, Bright.
Wrenches.

The former edition was received with so much favor by the trade that it manifestly met a want, and our advices from Hardwaremen indicate that these lists have been found exceedingly convenient for the purpose for which they are intended. The labor of writing list prices in price-books and the amount of space occupied have deterred many from keeping price books as thoroughly and systematically as is desirable, and it has been found that lists taken from printed catalogues are not usually sufficiently compact in form to make them suitable for this use. It may also be said that the lists issued by manufacturers and jobbers are not infrequently incorrect, and in the compilation of these lists especial care has been taken to give the standard list prices representing the best usage of the trade. The lists comprised in this collection have been prepared with especial view to compactness of arrangement and convenience of reference, the aim being to present each list in the smallest space consistent with clearness and convenience of use. No effort has been made to give the lists in a uniform size or shape, but simply in such a way as will make them occupy as little room as possible in the price book. The precise manner in which this is done must obviously be left to the merchants, who will adopt such methods as are most consistent with their views, the size and character of the price book kept, &c. Some of the small lists will most appropriately be gummed on some vacant space on the page where the prices of these goods are kept; but some of the larger lists may conveniently be inserted as a separate leaf between the pages of the book. Some of the lists are given in more than one arrangement, thus permitting a choice of such form as is best adapted to the use to which it is put, as, for example, the cards for Cut and Wire Nails, which are printed in two forms, one of which would run up and down the page and the other across the page. Some of the lists may be cut down so as to show only the goods which are carried in stock, or on which the merchant cares to keep prices, and room can thus be economized. These lists have been prepared with great care to insure their correctness, and it is believed that they will be found a convenience to merchants for the purpose intended. As a compact and convenient collection of standard lists covering a large variety of goods they will also be of service for reference in the form in which they are presented.

* Published by David Williams, 96-102 Reade street, New York. Price 25 cents.

The Hardware Club of New York.

The annual meeting of the Hardware Club of New York was held on Saturday, March 18, at 3 p.m., in the parlors of the Cosmopolitan Hotel, corner Chambers street and West Broadway. There was a goodly representation of the membership, and harmony and enthusiasm characterized the gathering. The meeting was called to order by the president, William H. Williams, who submitted a report on behalf of the Board of Governors, in which he referred to the history and plans of the club, reporting a membership of 228 resident members and 61 non-resident members. After referring to the contract recently entered into with the Postal Telegraph Cable Company for a ten years' lease of the top floor of the new building now being erected on the corner of Broadway and Murray street, the president's report continued:

It is expected that these rooms will be ready for occupancy by November 1 next. Favorable arrangements have been made with the Postal Telegraph Cable Company for putting in the permanent fixtures that will be required for the use of the club.

As announced in a former circular, the building is exceptionally well located for the convenience of the Hardware trade of New York, and in its general appointments it will have no superior in the city.

The amount which will be received from initiation fees of members will be sufficient, the board thinks, to enable it to fit up the rooms in a suitable and elegant manner, which will make the club what it was designed to be, a pleasant and useful meeting place for its members.

Next to securing permanent quarters, the principal event in the history of the club during the past year was the fifth annual dinner of the Hardware and Metal trades, celebrated under the auspices of this club at Sherry's, on the evening of February 21 last. The success of the meeting, socially, intellectually and gastronomically, amply justifies the efforts of those who had it in charge, and confirms the wisdom of having at least once each year meetings of a similar character of the trade in which we are engaged and those allied to it.

Reports were also submitted by J. L. Varick, secretary, and Thomas F. Keating, treasurer. The following nominations for Board of Governors, which had been duly made and posted by the Committee on Nominations, in accordance with the requirements of the constitution, were then reported to the meeting, and the gentlemen named were unanimously elected:

BRACE HAYDEN.
M. C. OGDEN.
CHARLES DALY.
THOMAS F. KEATING.
R. R. WILLIAMS.
J. H. KENNEDY.
R. H. SWAYZE.
E. C. VAN GLAHN.
A. G. SHERMAN.
W. R. WALKLEY.
W. H. WILLIAMS.
J. L. VARICK.
PETER MCCARTEE.
EUGENE BISSELL.
A. D. CLINCH.

It was then, on motion of William A. Graham,

Resolved, That it is the sense of this meeting that the action of the Board of Governors in leasing from the Postal Telegraph Cable Company rooms for the use of this club, as reported to this meeting by the president, meets with the approval of the members of this club.

The following resolution was then moved by A. W. Milligan and unanimously adopted:

Resolved, That it is the sense of this meeting that the treasurer of the club should call upon the members now for their initiation fees, in order that he may be in funds to meet the demands upon him as security for rent or fitting up the new rooms.

The meeting then adjourned. In accordance with the requirements of the constitution, the newly elected Board of Governors will, during the present week, assemble to be divided into three classes, holding office for one, two and three years respectively, and for the election of officers of the club.

Keeping Dates of Invoices.

An inquiry for a successful method, entailing a small amount of labor, of keeping in sight the dates on which invoices become due, so as to avoid being drawn on, or the loss of discounts, has elicited a number of replies.

The accompanying cuts are reproductions of plans in successful operation, and are of particular interest because of their variety.

Case & Uehren, Aurora, Ill., have for some years used a block calendar, as shown in Fig. 1, and find it very convenient for making memoranda of bills payable,

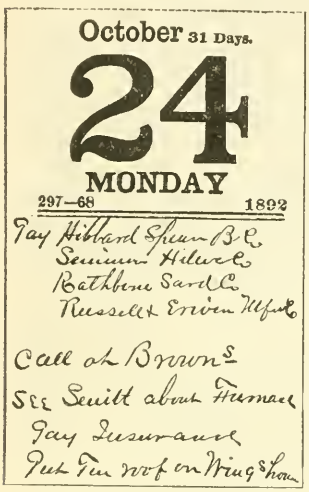


Fig. 1.—Case & Uehren's Use of the Calendar.

and of matters requiring attention on particular dates.

The plan of G. L. Phillips, Bethany, Mo., as shown in Fig. 2, gives a page to each month, and is ruled by himself. It gives the page on which the bill is entered, name of the firm, the date when each bill was paid, amount of the invoice, its date, time to run, date due, cash discount, and the amount of discount. In addition to this it is a record of the amount of goods purchased each month, and the total amount of discount for the month. By adding these monthly amounts together the total for the year is soon arrived at.

Day & Holt, Catskill, N. Y., use a well-bound four-quire record book, and rule it as shown in Fig. 3. When an invoice has been checked and footings and prices found correct, it is entered under the proper month, the date on which it becomes due. The dates near the left-hand corner of the page are in red ink and represent the Sundays in the month. Having these dates in sight, if an invoice should be dated September 1, based on ten days' payment, it is seen that it is due on the 11th, which is Sunday, and, therefore, it would be entered as payable on the 10th. It is the custom of the firm to pay on Monday such bills as become due during the current week, and stamp "Paid" in the column provided for that purpose. They find this plan answers the purpose, and is convenient, as at a glance they can tell how much they are owing. This they suggest tends to prevent careless buying at such times as a merchant might think he had small liabilities coming due, had he not some guide of this kind to show just where he stands.

When paying bills Day & Holt use the remittance blank with voucher, or blank receipt attached as shown in Fig. 4. This secures uniformity in size of receipts for filing, while the voucher number corresponds to the number of the invoice, for ready reference.

Sommer Bros , Portsmouth, Ohio, use a form much the same as shown in Fig. 2. They utilize pages in their ledger, the headings extending across both pages as follows: Date of invoice, month, received, name of firm, location, amount of invoice, freight, overcharges, freight rebate, rate of discount, amount of discount, amount of check, number of check, date about 3000 bills. The publisher explains the system as follows:

The bill-registering book shows the date of bill, amount of bill, the different rates of discount to which the bill is subject when it is due, the rate and amount of discount taken, the amount of cash paid and the date of payment, making a complete record of the bill from the time it is received until it is disposed of. It also makes a complete merchandise, discount and cash account, dispensing with the use of ledger accounts for bills payable. So far as the merchandise is concerned it enables the mer

chant to see at a glance which bills are paid and what are unpaid, and at what time he can pay them to save the greatest amount of discount. It also enables him at any time to see just the amount of merchandise bought, the amount returned, what shortages, claims or rebates stand charged against the bill, the amount of discount saved, and the amount of the actual net cash the merchandise has cost him. Each bill being numbered to correspond with number on register and filed consecutively, the bill file becomes paged like a book, and any invoice can then be very quickly and easily found.

paid, time and when due. They refer to this memorandum, being kept in their ledger, as avoiding the necessity of devoting a separate ledger page to each firm from whom they buy goods.

In answer to an inquiry, T. M. Clark, Bloomington, Ill., sends a sample sheet of Robb's Bill Register, published by him, of which Fig. 5 is a reproduction, reduced in size. The 150 pages in this book are each 8½ x 14 inches in size, properly indexed and paged, and will accommodate several years, advise us that they find it the most perfect system they have ever used, and as soon as one book is filled they order another. Referring to their manner of using the book, they remark:

We keep no other account of our purchases than in this book; the whole of each transaction is complete, and we are able to refer to it in a moment at any time, and it need not go on the journal at all.

In connection with this register a remittance blank is published, together form-

ing, it is stated, as nearly as possible, a barrier against mistakes; as a cashier receiving such remittance has an exact transcript of the register, and if incorrect, errors can be immediately detected.

Discount for Cash.

The English retail merchant as a rule extends longer credit to customers than is usual in this country. From the accompanying card, taken from a London paper devoted to the interests of the Hardware trade, it will be seen that there is a tendency to encourage a cash

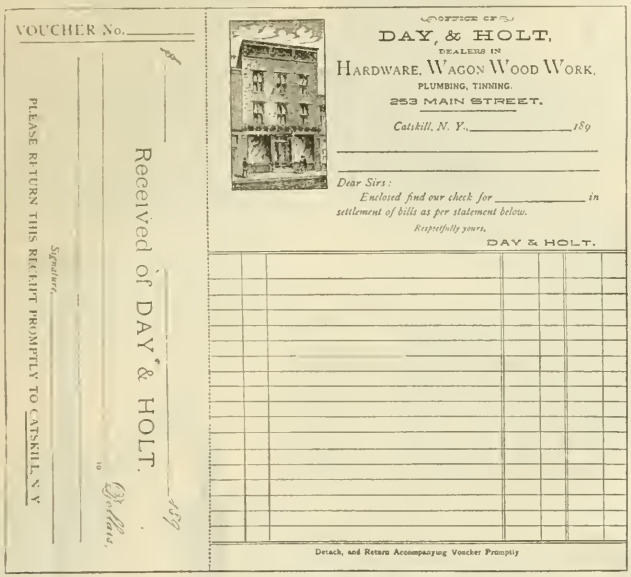

Fig. 4.—Convenient Remittance Blank (Reduced Size).

business. The card, which is about 3 x 4½ inches in size, reads as follows:

1D. in the 1S.

From All Goods paid for at the time of purchase at

TOLLIT'S

IRONMONGERY ESTABLISHMENT,

46, High Street,

ST. JOHN'S WOOD.

The cash discount which is offered, of one penny on every shilling's worth of goods, is equivalent to about 8 per cent. The card was extensively distributed by Mr. Tollit throughout the district tributary to his store. He has found the plan successful, as it has brought new customers, as well as pleased some of those who were in the habit of asking for credit. The suggestion this offers may be of service to merchants who are doing a part credit and part cash business, and who are desirous of educating their customers to pay cash for their goods. Whether the credit part of a business yields any considerable profit, is a question deserving consideration.

Cash or Credit.

The matter of cash or credit business is thus touched upon by a Hardwareman in Ohio:

It goes without saying that every retail merchant believes that a store run on cash principles is the ideal of business. Yet it is considered difficult in some lines to place one's sales on a strictly cash basis. Take for instance a Hardware store, where the sales are half cash and half credit, with the book accounts gradually getting the upper hand, it would seem that something ought to be done to turn the balance of sales on the cash side. There is no matter so disastrous to retail merchants as that of extending credit without proper discretion. The cost of keeping the books, collecting bills and loss of bad debts oftentimes equals the profit on credit sales. The man who wishes to pay cash and get full value for his money prefers to trade where his money goes furthest.

The dealer can afford to sell cheaper, since he has his goods or their equivalent always on hand, and is in a position to make money for his customers by discounting his own bills, thereby reducing the cost to his customer. We believe the time has come when the careful public will give preference to the cash store, and have therefore decided that on and after January 1 we will sell strictly for cash or its equivalent. Our prices at all times will be as low as is consistent with good goods and a fair margin of profit. We shall not try to make you believe we sell below cost, because the man who does is usually deceiving you, but we will aim at all times to please and give you full value for your money.

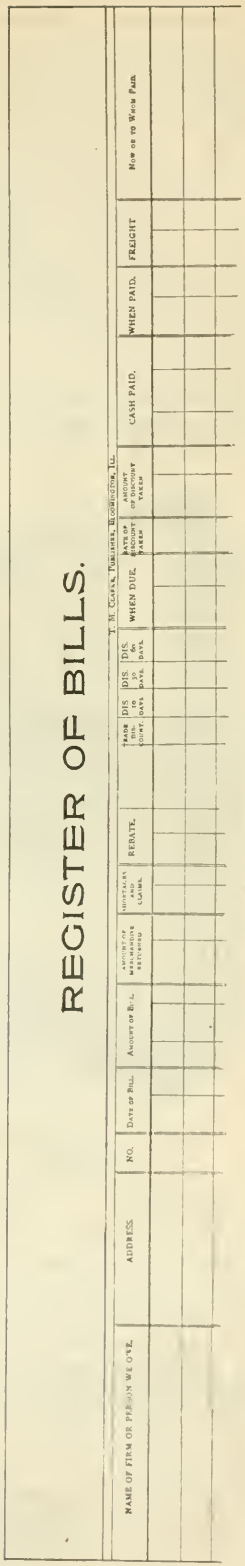

Fig. 5.—Robb's Bill Register.

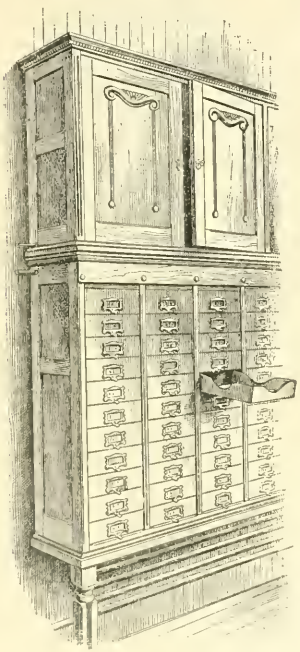
Catalogue File Case.

We are indebted to the W. Bingham Company, Cleveland, Ohio, for photographs of their catalogue file case, reproductions of which are given herewith. The cabinet is located in the buyers' office, and is used for filing pamphlet catalogues, lists, circulars, quotations, &c., of the various goods in the lines they carry. The filing case is 10 feet 10 inches long and 4 feet high and consists of 11 tiers of 11 compartments each. In front of each compartment is a slide, which when raised discloses a neat tray 12 inches long, 10½ inches wide and 3 inches deep, with sides and ends slashed to facilitate getting at its contents. The index used is practically that of *The Iron Age* Multiple Index Price Book E, and indeed it was this index that first suggested the idea of the cabinet, as it occurred to H. S.

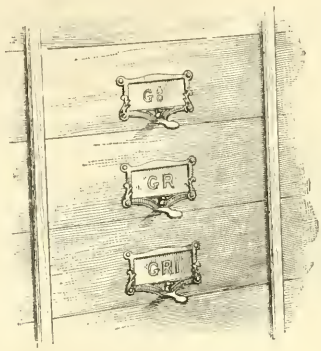


Catalogue File Case of the W. Bingham Company.

Blossom, the secretary of the company, upon examining this book, that a file, with this index would settle the vexed question as to how to conveniently care for the many small lists, &c., that it is necessary to have for reference. The index first put on the case was identically the same as that of Price Book E, but it was later found necessary to modify it, in order to relieve some trays that were too full, which was done by adding "Bells," "Locks," "Machines," "Pumps," "Refrigerators," "Tinware," "Tools," and "Wire Goods."

The whole is locked by simply turning a handle or fixed key at one end, and can only be unlocked by a key in the possession of Mr. Blossom's assistant, thus securing absolute privacy as to its contents.

As each list is filed under the name of the article listed, it is entered upon an index book under the name of the firm issuing it, the tray into which it is put being noted, so that it is but the work of a moment to find either the lists of any particular firm or all the lists of the makers of any particular article. There could hardly be an arrangement more complete or convenient, and the cabinet referred to is as satisfactory as a file as the Price Book E is as a register of quotations.



Enlarged View of Index.

On the top of the file is a cupboard 2 feet 9 inches high and 10 feet 10 inches long containing one shelf, and inclosed by six carved oak doors. This is used for large catalogues. The whole is mounted on legs 24 inches high, making the entire hight 8 feet 9 inches, the depth of the case being a trifle over 14 inches.

Eclipse Self-Measuring Oil Tank.

Wayne Oil Tank Company, Fort Wayne, Ind., are offering the self-measuring device shown in the accompanying illustration. The plunger rod of the pump is attached to a half circle connection, to which the lever is fastened, the object of this arrangement being to enable it to respond with greater ease and better results than a direct movement. The half circle contains the adjustments, which are made by means of thumb screws, as shown in the cut It is explained that the small nuts may be raised or lowered to suit the locality, and that the quart stop is made bysimply turning the handle without removing the handle from the lever. It is remarked that the measuring tanks can be made square as well as round, and that the pump cylinder is of seamless brass tubing, the valves of brass, ground air tight, and that all drippings return to the tank. When tanks are made square they are incased in a cabinet. If desired the tank can be placed in the cellar, and the measuring device on the first floor of the store. The point is made that no lamp is needed when drawing oil at night.

Eclipse Self-Measuring Oil Tank.

Steel Trowel and Weeder.

A. M. Ross & Co., Ilion, N. Y., are introducing these articles, as illustrated herewith. The garden trowel shown in Fig. 1 is made of steel, and is referred to as of good form, strong and durable. The steel weeder, Fig. 2, allows a person to stand erect when working. By inserting the tapered, half round steel blade into the earth beside a dock, thistle, planten, daisy or other weed, and then giving the hand a quarter turn, it is claimed the weeds and roots may be lifted out clean. The tool is designed for lawn, meadow or garden use.

Fig. 1.—Steel Garden Trowel.

Fig. 2.—Steel Weeder.

MEMORANDA.

THE HARDWARE BUSINESS of William Millspaugh & Sons, on West Main street, Middletown, N. Y., has been organized into a stock company under the name of the Millspaugh Hardware Company, the members of which are William Millspaugh and his sons, George M. and William M. Millspaugh.

THE BINGHAMTON HOUSE FURNISHING COMPANY have succeeded McElroy & Fancher of Binghamton, N. Y. In connection with the furnishing departments they have opened a handsome stove store, and will carry a full line of Fuller & Warren Company's rangea and heating stoves.

REYNOLDSON & METCALF, Primghar, Iowa, having outgrown their store accommodations, have erected a new two-story structure 43 x 123 feet of brick, with the lower rooms finished throughout with hard pine and metal ceiling. The Hard-

ware department is 23 x 60 feet; in the rear of which is a Tin shop, 15 x 30 feet. The Harness and Miscellaneous department is 23 x 60, with a Harness shop in the rear 15 x 15 feet. An implement sample room, 36 x 40, completes the lower story. The second floor is occupied as a carriage repository, in one room, 43 x 123 feet, reached by an elevator, 8 x 10 feet, upon which vehicles can be taken up and down.

SINCE TAKING the agency for the goods made by the Corning Stove Company of Corning, N. Y., some months ago, C. K. Converse, the Wellsboro, Pa., hardware dealer, has disposed of 125 stoves and ranges.

W. H. CRANE & SON, successors of Crane & Parker, stove dealers of Binghamton, N. Y., have refitted their store at 14 Court street, and have an elegant line of stoves and ranges. The new firm have a bright prospect.

THE PARTNERSHIP heretofore existing between E. J. Troxel and P. A. Martin in the Hardware business at Minonk, Ill., has been dissolved. Mr Troxel has retired and Mr. Martin will hereafter carry on the business alone.

Monarch Broiler and Odorless Fry Pan Combined.

Maltby, Henley & Co., Rocky Hill, Conn., are introducing this household utensil, as illustrated herewith. As shown in Fig. 1, the lug on the lower edge of the pan fits into the slot of the casting, and when the pan is in place over the casting, holds it in position as the pieces are

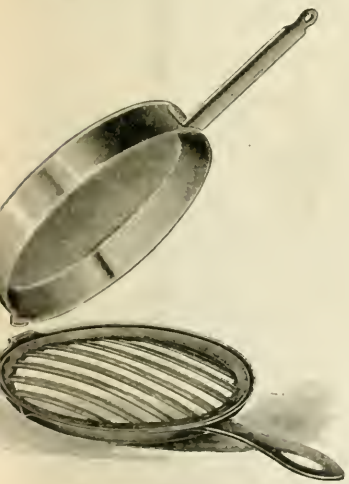


Fig. 1.—The Monarch Broiler.

reversed, or serves as a hinge when the pan is raised at right angles to the casting, and holds it in position. In Fig. 2 the broiler and pan are in position for broiling the steak, while in Fig. 3 is shown the pan as used with a cover, which accompanies every broiler or pan. The arrow indicates the opening through which the odors and smoke are sent up the chimney, when used with the stove lid removed; or when used on the top of the stove, the odors and smoke are designed to be almost wholly absorbed in the heated jacket underneath. It is remarked that the combination is a simple one; that its merits are quickly seen and explained, and that it covers many points that please. It is explained that the pan is made in one piece from Swedish steel, smoothly ground and polished inside with the riveting all on the outside piece, obviating any chance for leaks or disfigurement on the inside. The points of excellence are enumerated as follows: A complete broiler and fry pan are combined, avoiding the smoke and odor in both; an ordinary fire doing good work, not being checked while broiling; the whole outside of the cooking part is exposed to the fire, it heats quickly and holds the heat when the pan is removed; the pan rests on the beaded rim, preventing wear on the bottom, and is not easily turned over. It is claimed that the fry pan or broiler can be used with great satisfaction over gas or oil stoves, and that because of the peculiar construction of the pan it not only fits any stove hole, but catches the flame on oil and gas stoves, so that it heats quickly and evenly and absorbs the smoke and odors arising from cooking.

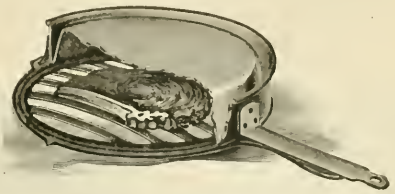

Fig. 2.—Broiler in Position for Use.

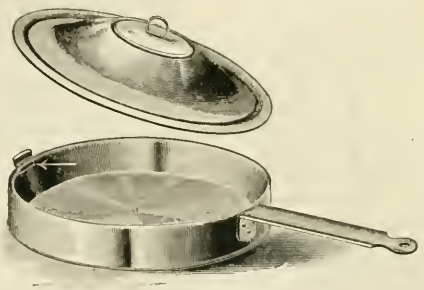

Fig. 3.—Used as an Odorless Fry Pan.

The Buckeye Churn.

The Bukeye Churn Company, Sidney, Ohio, are offering the form of churn as illustrated in Figs. 1 and 2, embodying the principle of concussion to produce

Fig. 1.—The Buckeye Churn.

desired results. In alluding to its construction and operation, the manufacturers state that it requires but one fourth the power crank or dash churns do, as by rocking the churn backward and forward the barrel is thrown on an inclined plane alternately from one end to the other, thus dashing the contents by its own weight into spray, and that the rebound or reaction, in connection with the mechanical fact that the fulcrum at the bottom of rockers changes from one to the other in accordance with the change in weight, balances the weight in its motion, thereby saving three-fourths of the labor required with other devices. The manufacturers claim that the apparatus does not heat by exercise; that it has no rim of cork to leak or get sour; that it is always open to admit air and prevent accumulation of gases, and that there are no cogs or journals to get out of order. The point is made that

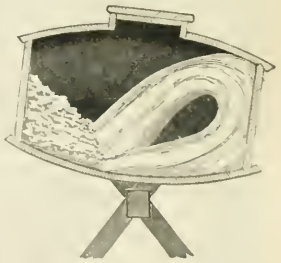

Fig. 2.—Showing its Operation.

the barrel is made of selected white oak staves thoroughly seasoned, varnished in natural wood, strongly and substantially put together.

A mechanic arts building will be erected in New York at a cost of $200,000, through the munificence of a lady who presents that amount to the Teachers' College.

A number of small storage battery electric steamers are to be built at Tacoma to ply between that point and all Puget Sound routes, as the entire shore line is settling up rapidly, and the new boats will in effect be extensions of the city car lines. These boats are 56 feet long and calculated to make 15 miles an hour.

STOVE TRADE NOTES.

The Stove Convention.

The meetings of stove manufacturers, held in Chicago last week, were of a special character, called to consider a subject which was not deemed by them of public interest, and therefore did not receive the attention from the trade press which is always accorded the annual stove conventions. The object of the gathering, however, was of sufficient importance to be considered of great interest to the public. Anything which directly concerns such a prominent industry as the manufacture of stoves, enlists the attention of the public. We have, therefore, endeavored to secure more extended details of the transactions than were published last week, but have been forced to be content with merely a brief report of the result accomplished.

The general meeting of stove manufacturers on Friday, which followed that of the Stove Defense Association on Thursday, was the first general meeting of stove manufacturers held in 15 years. Invitations to attend it had been sent to every manufacturer in the United States, and in no way was it connected either with the National Association of Stove Manufacturers or the National Defense Association, except as it might be considered as an advisory body to the latter. Every section of the country was represented in the attendance except New England. Letters from the New England manufacturers, however, as well as from large numbers of other manufacturers unable to attend, were received, in which strong ground was taken against an advance in molders' wages, claiming that it would be impossible to comply with the suggestion of the molders to advance the price of stoves in proportion. We are advised that over 70 per cent. of the stove-producing capacity of the country was represented at the meeting.

The request of the molders for a 15 per cent. advance was very thoroughly discussed. The condition of the stove trade was exhaustively considered. Every possible aspect of the subject was brought up, and the relation of the stove business to other trades was very carefully considered. In view of the general tendency downward of prices of staple commodities, it was finally determined by a unanimous vote that it would not be possible to advance the price of stoves, as an advance if made would only curtail consumption and injure both manufacturers and employees. The matter was then by formal vote turned over to the Stove Defense Association, to be properly handled by them.

A meeting of the Stove Defense Association was called immediately after the general meeting had adjourned; and, after some further discussion of the question, the officers were directed to advise the molders that their request for an advance in wages would be refused. This notification was forthwith sent, and it now remains to be seen whether the molders will accept the situation, or will insist upon the advance. In view of the fact that wages are being reduced in other vocations, it would seem wise for them to continue the present arrangement and await the return of general prosperity to the country to press the demand for an advance.

The Keeley Stove Company

of Columbia, Pa., are distributing a very attractive catalogue of 100 pages, relating to the Columbian stoves, ranges and furnaces, which they manufacture in great variety. The Columbian line of goods will be exhibited at the World's Fair, and the manufacturers will spare no effort to make their display a leading attraction. The opening pages of the catalogue contain some valuable suggestions for those who have occasion to order stove repairs, and in connection with which is a price list of fire-brick stove lining furnished by the company. The first construction considered in the catalogue is the Columbian Newport, a new range with elevated boiler, made with or without warming closet, and both right and left hand. It is offered in three sizes and embodies the latest features. The Columbian Choice is a neat six hole range, made in several styles and sizes and having a triplex grate, capacious oven and with an open end at which the ashes can be removed. The Columbian King is a member of this class, as is also the New Capello, a heavy, strong, six-hole range, with fire-box adapted for hard coal, soft coal or wood. The bed plate of this range is made in two parts, so that the grate may be taken out and replaced without disturbing the water back. The Columbian Plato, made in five sizes, is of attractive design, and the materials used in its construction are said to be of the very best. The Triplex grate is illustrated and described, together with a variety of high shelves, closets, &c. Some of the other goods include the Columbian Star, made with the modern improvements and decorated in an attractive manner; the Columbian Charm, a six-hole range made with right and left hand ovens and with parts so disposed as to give very satisfactory results in baking and roasting; the Columbian Dandy, a neat cheap range made in five sizes; the Columbian Gem, another member of this class; the Vim and the Columbian Queen. The cook stoves are represented by the Regulator, Golden Grain and Columbian Dora, made for coal or wood; the Columbian Alliance, a cheap wood cook made in two sizes, and the Miner's Friend, a coal stove made in one size. The leading heater is known under the name Columbian Art. It is handsomely treated with nickel and art tile and is made in two sizes. Each stove is a double heater and the system of circulation is said to be complete. The cold air is taken from the floor, carried through the stove and discharged through the heat pipe collar. A sectional view of the stove is presented showing the various parts and indicating the readiness with which the stove may be dismounted when desired. The Columbian Cadet, made with revertible flue and tea-kettle attachment; the Morning Light, a sheet iron cylinder surface burner; the Grip, an all-cast construction; the Luxury, a very neat open stove with sheet-iron back and dust flue; the Columbian Prize, a Franklin, made with round fire pot suitable for natural gas and hard or soft coal; the Columbian Ulster, a heavy cannon, and the Morning Light, Columbian Vulcan and Columbian Ulster furnaces, are some of the other goods to which the attention of the dealer is invited. A miscellaneous assortment of stove hollow ware, prices, &c., complete the work. Accompanying the catalogue is another devoted exclusively to the company's line of furnaces. These are described at greater length than in the larger work and prices are given of each of the sizes made. The binding of the catalogue is in colored paper covers with side title consisting of a picture representing a cozy interior with one of the company's heaters as a prominent feature.

Claims for Castings Broken in Shipment.

A correspondent who has read the series of articles which have appeared in these columns for a few weeks past, on the general subject of claims made for castings broken in transportation, sends us the following letter:

An article in *The Metal Worker* of the 11th inst., with the above heading, is of great interest. I would suggest to manufacturers that they get up blank forms and send them to dealers to fill out, and present to the carriers of freight. The reason the dealer goes back to the shipper is because he does not understand how to apply to the railroad company for damages, owing, no doubt, to the fact that the railroad companies require a great deal of red tape to be gone through with before any result can be reached. I think if the manufacturers would get up blanks for the dealers to fill out and present to the railroad companies, it would save a great deal of money. The dealers should also be given instructions of just how to fill out the blanks, and how to present them in case of claims for damages. They should also be instructed how to file shipping and freight bills, and such other papers as may be necessary to file, with the railroad companies. The manufacturers know better than the retailers how this should be done. Many of the retailers will not take the trouble to find out how it should be done, and the agent for the railroad company will not receive the document unless it is presented according to the company's rules. The result is, that dealers reach the conclusion that they can write to the shipper and secure greater satisfaction, so they do not bother the railroad companies.

The Weir Stove Company, Taunton, Mass., resumed active operations on the morning of the 17th inst., after a brief shutdown.

Imitation of Ornamental Wrought-Iron Work.

BY JOS. LEON GOBEILLE.

There can be no question regarding the artistic value of ornamental wrought iron work. Its intrinsic value is definitely settled also, for modern pieces, such as grills, lamps, fenders, &c., fetch large sums of money, is of good design, while genuine antique specimens bring almost fabulous prices—in some cases much more than their weight in silver. Now in just the proportion that ornamental wrought iron is good and worthy, any imitation is meretricious and valueless from an æsthetic standpoint, and yet the age we live in is so intensely practical, so anxious to have the form even without the substance, that from present indications in a few years much that purports to be of wrought iron will be of cast, treated with some dark solution by electro-deposit or finished in the Bower-Barff style. Recently a considerable number of pieces of imitation work have been designed and finished under the writer's supervision, and, as a simple statement of how the work was done may be of interest, the following is presented* as a good example of this class of work.

Fig. 1 shows the preliminary sketch, which was made to answer two purposes: to get the approval of the firm ordering the work, who are quite particular in matters of design, and to serve as a guide for the modeler.

Fig. 1.—Preliminary Sketch.

Fig. 2 is a representation of the Bracket modeled up in clay, a necessary preliminary to carving the pattern in all work demanding anything like artistic treatment, the reason for this is that slight modifications materially change the character of a design, and these changes are easily managed in a plastic material, as wax or clay, though exceedingly difficult, if not impossible of attainment by the wood carver without a model.

Fig. 2.—Bracket Modeled in Clay.

Fig. 3 shows the two faces of the pattern, midway in the process of carving; this part of the work must be done with great precision in order to get the effect; it must, of course, have uniform draft, so as to come readily out of the sand; but only the least possible amount of incline can be tolerated.

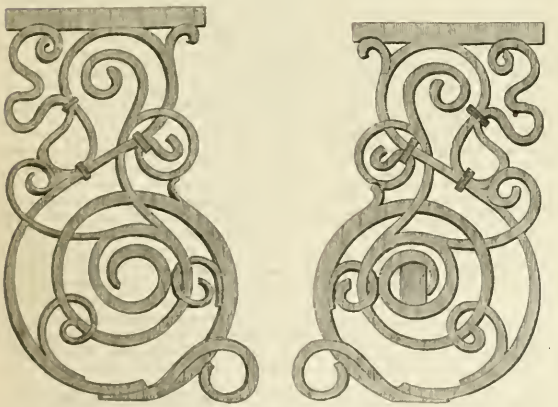

Fig. 3.—The Two Faces of the Pattern Partly Completed.

Fig. 4 gives a view of the pattern completed, glued on to a match board and in a snap-flask. Here, again, much care has to be exercised so that the two halves make the finished casting without defects.

All the curves, every outline in fact, of both the sides, must exactly coincide with each other and the match board and flask must come straight and plumb so that they will go together easily, but precisely the same way every time. Finally, only the best sort of molders should be put on this class of work; men who take more pride in the finished product than in the number of flasks they can put up before the wind goes on.

Fig. 4.—Pattern on Match Board in Snap Flask.

* By permission of the Chicago & Erie Stove Company.

ODD PLATES.

THE NATIONAL VAPOR STOVE & MFG. COMPANY of Lorain and Cleveland, Ohio, favor us with an exceedingly attractive catalogue of 56 pages which they have just issued, relating to the National gas and gasoline stoves. In offering this publication to the trade the manufacturers call especial attention to the New Idea Stove as placed upon the market for 1893. The principle of the New Idea is said to be a combination of the hot and cold process of generating gas from gasoline. The company utilize the cold process of generation for initial lighting, and, after the stove is started, hot generation. The construction is simple and the parts are put together with machine screws. It is claimed that there is no difficulty in lighting the burner, nor is there any odor emanating from it when extinguished. Another point to which attention is invited is that every part of the burner and

tubes is made of brass or cast iron, no sheet metal being employed. The company also have an interesting line of junior stoves, which are carefully illustrated in the catalogue before us. The descriptive letter press is full and covers the principal features to which the manufacturers desire to direct attention, while the illustrations are clear cut and satisfactory. The assortment of goods shown is a large and varied one, and the dealer is likely to find within the covers of the catalogue much that will interest him.

S. Bowen's Sons of North Penn Junction, Philadelphia, are putting upon the market a new stove putty, which they state is the result of experiments, extending over 15 years, in attempts to produce an article to withstand the highest degree of temperature and yet be sufficiently soft to make application easy and effective. The putty has been subjected to the most severe tests, and the makers claim that it can be left in bulk on a bench for several days without a covering, and will not harden enough to interfere with its working properties; yet when subjected to heat it will harden to a stone-like consistency without crumbling. The makers also claim that the new putty, to which they have given the appropriate name "Indestructible," will stick to the iron much better, has no odor or smell when the stove to which it is applied is first used, is much lower in price than furnace cement; keeps in the package much better, is more readily applied, and hardens slowly on a joint, thus allowing a mounter to putty up a line of stoves before putting the plates together. Generous samples of the putty have been sent to some of the leading stove manufacturers, with requests for practical and severe tests, and the reports resulting therefrom have been eminently satisfactory.

The Corning Stove Company of Corning, N.Y., will soon begin the manufacture of furnaces in conjunction with their large lines of stoves and ranges.

J. J Wilson, who is well known to many in the trade, has been with the Fuller & Warren Company, Troy, N. Y., since the first of the year, traveling in their interests, and selling furnaces, combination heaters, hot water and steam boilers. Mr. Wilson reports that the trade has been very excellent in the lines which he handles. Since the first of the year he has traveled in Pennsylvania, Maryland, and portions of West Virginia.

Robert Schueler & Co. of 615 Ogden avenue, Chicago, Ill., are offering the trade a line of gas ranges specially adapted for all kinds of baking, broiling and roasting. The goods are made under the name "American," and are turned out in a variety of styles, with or without water heater. The manufacturers refer to the operation of these ranges as being entirely satisfactory, and the design neat and tasteful.

The "Majestic Range Cook Book" is the title of a pamphlet which is being distributed by the Majestic Mfg. Company of St. Louis, Mo. Within its colored paper covers the leading lines of stoves are illustrated and described, following which is a long list of recipes of interest to the housewife. These cover a wide range, and are sent out with the statement that they have been carefully tested, and can be used with the certainty of success.

The Baxter Stove Company of Mansfield, Ohio, have just issued what is known as Catalogue No. 3, relating to their line of Monarch gasoline stoves and ranges. The work is printed in two colors, and is bound in colored paper covers of attractive design. The frontispiece is a bird's-eye view of the company's works, while facing this is a picture consisting of a group of photographs representing the late Mr. Baxter, president of the company, and his seven sons. The manufacturers state that the many improvements and developments made by them for the year 1893 cannot be shown in the illustrations, but they feel confident that an examination of the pages of the catalogue will give some idea of the labor and genius that have been employed to make the Monarch goods first class in every particular. The salient points to which the company call special attention are, "originality in design, novelty of features, perfection of mechanism, varieties in styles, and completeness of details." The first stove in the catalogue described is the Regal Monarch, a cabinet range which has been greatly improved for this season. It is fitted with patent air-blast oven and broiler burner, cast top and frame and cut-off cap, by means of which the generating flame may be reduced to a very low consumption and the entire line of burners fully operated. In connection with the Monarch New Method, special attention is directed to the direct action valves, Baxter's patent side feed and Baxter's patent vaporizing chambers. A varied assortment of Monarch Juniors is also shown, together with illustrations of ovens, broilers, steam cookers, &c.

According to the annual statement of the Employees' Mutual Benefit Association of the Michigan Stove Company, the disbursements during the past year in the shape of benefits amounted to $1115.37. The total amount paid in benefits since the organization of the association May 12, 1882, is $15,781.87. The organization is conducted upon the co operative plan, and thus far has proved a great success. A large number of employees of the company named have received benefits from the sick fund, which has enabled them to tide over a period of illness which otherwise would have proved very serious.

A simple apparatus, by means of which the exact quantity of water may be placed in the evaporating pans for the purpose of moistening the air in hot-air furnaces, is the basis of a patent recently granted to Joseph F. Jeffrey of Shell Lake, Wis. The arrangement is such that the device is placed near or within the hot flues and the evaporation controls the humidity of the air entering the flues. The evaporating pans are so constructed that they may be made to evaporate more or less rapidly as desired. The object of the inventor is to produce an apparatus which may be cheaply made, easily controlled, and which will accurately regulate the quantity of moisture with which the heated air is charged.

The Gobeille Pattern Company of Cleveland, Ohio, are completing the erection of their shop No. 3, a three-story brick building 68 x 70 feet. The equipment of the new shop will be modern throughout, the very best appliances that could be secured having been placed in it. Operations will probably begin during April and about 75 additional men will be employed.

Armstrong & Co. of Baltimore will shortly put upon the market a new stove, which will to a certain extent embody the good qualities of their Helper range. It will be fitted with a horizontal boiler and a warming closet. The company will make two sizes, No. 7 and No. 8, each with right or left hand fire box, as may be required.

The Magee Furnace Company, 117 Beekman street, whose plans were made to occupy their new premises at 242 Water street some time in January, were obliged to modify their arrangements somewhat, and took possession of their commodious quarters during the past week. This removal, they say, is occasioned by the increase of their business, requiring greater facilities to handle it. A new line of samples will be set up and the interior lighted by electricity.

The Calder Coal Oil Burner & Stove Company is the name of a concern recently incorporated at Omaha, Neb., for the manufacture and sale of a patent process for burning coal oil. The capital stock is placed at $4000, and the incorporators include C H. Pinney, Lewis Hammer, C. C. Cook, M. Pusey, F. P. Seybert and William Moore.

The Howard Furnace Company, Syracuse, N. Y., recently invited their managers of branches and salesmen to Syracuse for the purpose of exchanging ideas, views and experiences, partaking of the nature of a conference as to how the mutual interests of all could best be promoted. The meeting was held March 9, and after the conclusion of the discussion for which they were assembled, those invited were entertained at dinner at the Yates, the president, E. M. Moore; vice president, J. H. Norton, and treasurer, F. H. Moore, acting as hosts. C. D. Howard was unable to be present. A neat speech was made by the president, and complimentary resolutions of an informal character were offered and adopted by those present in appreciation of their reception. There were present: W. B. Wilkinson, New York; J P. Healey. Boston, and Mr. Tyler, Grand Rapids, managers of branches, and G. A. Stevens, covering lower New York. New England and New Jersey; Mr. Van Keuren, who looks after Central and Northern New York, and Messrs. Foord and Beers, who attend to local business around Syracuse and vicinity.

A tile fastener, intended for use in attaching art tiles to stoves, has recently been patented by A. M. Strusholm of Woodbridge, N. J. The invention consists of a suitable device, which can be readily attached to the stove or frame rod provided therefor, and is so shaped at the projecting end as to fit within dovetailed grooves formed in the tiles. A spring clip embraces the frame rods at any desired point, the clip having its end formed to correspond with the dovetailed recess or groove in the tile.

Charles T. Corby, whose present warehouse and headquarters are at Ralph avenue and Broadway, Brooklyn, will be at 117 Beekman street, New York, after March 20, occupying the premises lately vacated by the Magee Furnace Company. Mr. Corby carries a large stock of oil and gas stoves and stovemen's supplies. He is agent for Hoyt & Wynkoop, manufacturers of oil stoves; also for Schneider & Trenkamp, makers of vapor and gas stoves. The building in Beekman street will be used as a display room and shipping department.

A gas cut-off intended to prevent the escape from a stove into a room of disagreeable odors after the supply of oil from the reservoir has been cut off has recently been patented by Annie Sayers of Chicago. The cut off is adapted to be applied to the burner of a gasoline stove of any description, but is found to be especially adapted for use in connection with what are known as the new-process vapor stoves. The gasoline is admitted to a mixing chamber from the reservoir through a needle valve and drips through a tube to a vapor chamber formed by a cylinder. The vapor rises to the burner, at the top of which it is ignited. As soon as this takes place the vapor within the center tube also ignites and burns at the bottom of the tube, heating the barrel or cylinder above referred to, as well as the central tube. The heat thus generated causes a rise of air in the tube, which passes into and cools in the vapor and air chamber, thus causing it to descend through a vapor pipe and fill the

vapor chamber with gas and air. When the supply of gasoline from the reservoir is shut off by the needle valve, the flame at the top of the burner goes out owing to the excessive supply of air for the amount of gas remaining in the chamber. To prevent offensive odor escaping into the room the gas cut off is so arranged as to cover the top of the burner, and when applied the gaseous vapor is caused to be consumed at the openings of the lower end of the central tube previously referred to. This latter tube being open at the bottom and top and the cap centrally perforated, permits of a free passage of air to supply the flame at the openings at the lower end of the central tube.

IN A NOTICE in *The Metal Worker* last week of the catalogue of the Excelsior Steel Furnace Company of Chicago, it was mentioned that the material from which their fittings were made was IC tin plate. It should have been added that the company are prepared to promptly furnish these fittings made of IX plates, which is the weight required very largely by the Eastern trade.

THE BUILDING at 51 to 53 South May street, Chicago, partly occupied by W. J. McKay & Co., was damaged by fire on the night of the 22d inst. Their stock of stoves filled an entire floor and occasioned the firemen some anxiety. It was feared that the great weight on that floor would cause the walls, weakened by fire in other places, to give way, and everything was done by the firemen to keep the fire as much as possible from that floor. This was done so successfully that the firm's loss will probably not be over $10,000, covered by insurance.

A GAS BURNER having a greater number of openings than in the ordinary circular burner and means for preventing the escapt of unburned gas, which makes an unpleasant odor, is the subject of a patent granted February 28 to Herbert Clayton of New York City. The inventor makes the construction in such a way as to feed the air between the escaping and burning gas flames, allowing it to mingle therewith and produce complete combustion. He further provides against the escape of unburned gas by feeding to the outside of the flames a current of air in such a way that the air mingles with the burned gas and causes the entire volume of gas to be consumed. Another object of the invention is to give a uniform heat to the under side of a vessel placed upon the stove, by distributing the flame entirely over its bottom instead of burning it in a ring as in the ordinary burner. A still further object is to provide the device with a small central burner and a chamber for feeding gas thereto, while surrounding it is a larger burner also having a chamber. Means are provided for admitting gas to the small central burner only when the valve is turned a slight distance, thus preventing the escape of unburned gas through the large burner, and then admitting gradually the gas to the large burner as the valve is further opened, thus making it possible to have only a small flame without the escape of unburned gas into the room in which the device is placed.

J. B. COPP, manager of the Chicago branch of the Peninsular Stove Company, has made a number of improvements in his warehouse and sample room. The offices have been removed to the second story and handsomery refitted. Being further from the street, less annoyance is experienced from drafts, dirt and street noises. The sample floor has been considerably increased in size by the removal of the offices, and has been redecorated, making a remarkably fine room, more suitable for the display of the high grade goods manufactured by this company. These improvements have been made by way of preparation for the proper entertainment of their customers, who are expected to visit Chicago in force during the World's Fair.

WE HAVE RECEIVED, with the compliments of J. E. Walsh & Co. of Warren, Mass., an exceedingly pretty announcement in the shape of a four page folder, designed by Livermore & Knight, Providence, R. I. The front cover carries a panel picture representing a landscape scene in summer, while upon the third page is an illustration of the Highland Grand range and the announcement that Messrs Walsh & Co. have secured a store on South Bridge street, Warren, Mass., where they will carry a full line of stoves, ranges and kitchen furnishings, and will be prepared to execute first-class plumbing, tin, copper, and sheet-iron work, hot-water, steam and gas-pipe fitting. The firm is made up of John E. Walsh and H. A. Tannerbring.

WILLIAM L. MITCHELL of New York City has patented a gas burner so constructed, it is claimed, as to obtain a more thorough and uniform mixture of the gas and air before combustion, while at the same time making the pressure on the mixer uniform upon all parts of the burner, so that the amount of flame may be easily regulated to any desired degree between two extremes. The general form of the burner is annular and is designed to produce a flame on the inner periphery on the annulus, and an independent flame on the outer circumference. The two flames are fed independently, and when a minimum of heat is desired the supply of gas is cut of entirely from the outer flame or burner, while the inner burner is turned to its lowest point. When both flames or burners are under full pressure the maximum heat is secured. Between these two extremes the inventor claims that any desired degree of heat may be obtained.

GRAFF & CO., 208 Water street, New York, are now offering the trade a new range, which they have designated Columbian. It has double ovens, and is similar in construction to their well-known Faultless. The new feature is the method of treating the section over the fire box. Instead of four covers, with a long center, and two smaller ones, there is a removable frame, inside of which is a short center supporting two covers or lids, 8 inches in diameter, outside of which are rings ½ inch wide, thus affording a choice of either 8 or 9 inch holes, according to the needs of the housekeeper. Then, instead of the former arrangement, the removable frame runs the same way as this fire box and directly over it, permitting the whole fire surface being utilized whether for broiling, toasting or other purposes, where direct contact with the fire is necessary. Then, too, in laundering clothes, the ordinary wash boiler can be placed in the smaller oblong hole by removing the covers and rings, or the modern large-size square boiler by taking out the entire center. The range can be furnished in brick set or portable, right or left, &c. This house have also added for this season's trade a new style front to their line of Hero furnaces, consisting of a solid cast-iron front, which is fastened to the body of the heater in one piece instead of two, as heretofore. This furnace is now made in three styles—viz., steel tubular radiator, revertible flue cast-iron radiator, and what is usually known as sweep flue soft coal radiator.

A HEATING DEVICE for use in connection with gas jets or lamps has been patented by William Rennyson of Morristown, Pa. The object of the present invention is to produce a device which shall be cheap and simple in construction, efficient in action, ornamental in appearance and more easily taken apart for transportation and cleaning purposes. The globe or reservoir, is supported above the flame of a gas jet or oil lamp in such a way as to receive and temporarily confine the hot gases as they ascend from the flame and radiate them downwardly and outwardly into the room whereby, it is claimed, the heating and lighting capacity of the flame are greatly increased.

SCRAP.

BRITISH BOARD OF TRADE RETURNS for the month of February show a falling off in the shipments of tin and terne plates to the United States of over 3000 tons, as compared with the exports in February, 1892. The figures are: 1892, 23,268 tons; 1893, 20,190 tons.

N. & G. TAYLOR COMPANY of Philadelphia, Pa., send out a circular letter inclosing a description of their tin-plate works, from which they say they are now turning out American tin plate at the rate of a complete finished box per minute. They refer to the manufacture of tin plate in this country, and describe briefly the elements that enter into its cost. Reference is also made to the recently published statistics of the product of tin plate in America.

A LETTER SIGNED by Alfred Marshall was published in a recent issue of the Philadelphia *Press*, commenting on an editorial which appeared in the *Times* relative to the American tin industry. Mr. Marshall who, as the trade know, is in a position to speak from intimate knowledge, points out the fact that the large majority of the American tin-plate works are run by American labor. Americans, he said, after a few months' experience are thoroughly competent to turn out as much tin plate, and equal in every respect to the best imported. They are also more reliable in doing their work. Mr. Marshall likewise refers to the recently published statistics on the manufacture of American tin plates.

AT THE CONCLUSION of the last monthly meeting of the Iron and Steel Sheet Manufacturers' Association an informal talk was had by four or five tin-plate manufacturers concerning the advisability of having a display of tin and terne plate at the World's Fair. The question of having an exhibit showing the process of mining the ore, smelting it and of cutting the sheets, and all details connected with the manufacture of tin and terne plates, was discussed, but no definite action was taken. It was hoped the attendance of tin plate manufacturers would have been larger, but as only four or five concerns were represented, definite action on this subject was postponed until a later date.

The Nicaragua Canal Construction Company have purchased the ocean steamer "President Caraza," to be added to their fleet, making nine vessels owned by the company. The new steamer is American built, and it is the intention of the company to use the boat for shipping supplies and employees to the canal works from American ports.

The net profits of the Cunard Steamship Company last year were only about $150,000, on account of low freights and loss of steerage traffic.

New Orleans is promised an abundant supply of coal from the mines in Georgia and Alabama, the Richmond & Danville Railroad having arranged, through its Georgia Pacific branch, for a line of barges to run between its termini on the Mississippi and New Orleans for transporting coal.

TRADE REPORT.

The Iron Market.

There has been an increased demand during the past week for Iron and Steel without any pronounced change in prices. In some lines prices are a shade better, in others they are easier, so that there is nothing to be claimed as a distinctive advance in price, taking the market as a whole. A large quantity of material is being used, for which there is likely to be an increased demand when trade is fully opened; but a remarkable feature of the situation is that while consumers have plenty of orders they claim to be making little or no margin of profit, and are inclined to complain that they are doing a large amount of business for a small compensation. There is the best of reasons for believing that there are more hands employed in Philadelphia and its immediate vicinity and on fuller time than at any period on record. We refer, of course, to Iron workers only, which in the city alone aggregate between 30,000 and 40,000 hands. In view of such facts as these, it seems paradoxical to say that business is in poor condition, yet that is about the usual report. The Baldwin Locomotive Works alone are working nearly 5000 hands, turning out 20 engines per week; the Cramps and the Disstons make another 5000 between them, with quite a number of concerns running from 750 to 1500 each, among which may be mentioned the Southwark Foundry & Machine Works, Bement, Miles & Co., Wm. Sellers & Co., the Enterprise Mfg. Company the Allison Mfg. Company; and with 500 to 700 each, may be mentioned such concerns as the Geo. V. Cresson Company, Hoopes & Townsend, G. & H. Barnett, Isaac A. Sheppard & Co., and the Abram Cox Stove Company. Up the Schuylkill Valley, and especially at Reading, similar activity prevails, but they all say the same thing—no margin for profit. It is difficult to explain why such is the case, but that it is so in many departments of trade is a fact too well known to admit of denial.

Recent interviews with a number of the leading Iron and Steel manufacturers of Pittsburgh elicited the information that the prospects for a heavy business in nearly all kinds of Raw and Finished material are highly encouraging. The volume of business to day is much heavier than one month ago, and when spring trade has fairly opened up there will be a still heavier demand for Iron and Steel products. A very pleasing feature in connection with the improvement in the business situation is the fact that it not only applies to demand, but also to prices, although in not so marked a degree. Since February 1 we have seen Bessemer Pig advance nearly $1 ℔ ton, and it is in active demand to-day at $14 ℔ ton. Billets are fully $1.50 ℔ ton higher, while the immediate products of Soft Steel have also scored material advances. In Structural Material, Plates, Steel Bars and Merchant Steel there is too little difference between the price of the Finished and the Raw Material, and makers state that these must advance in price on account of the sharp advances in Pig and Billets. The Ore question is an important factor in the situation just now. The impression prevails that just as soon as the Ore sellers and furnace owners come to an understanding, its immediate effect will be in the nature of further advances in Bessemer Pig and Billets. More anxiety has been shown during the past week by the furnacemen to close up with the Ore people than existed several weeks ago. It is accepted as a fact that the shoving up of prices for Pig by the furnacemen has given considerable strength to the backbone of the Ore interests, and further advances in Pig will continue to strengthen the position of the Ore men.

The leading Northern furnace interest represented in the New York market reports that old customers are booking orders quite freely for Pig Iron, and that shipments thus far this year are much heavier than they were a year since. Complaints are again being heard of delay in delivery of Southern Iron. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14 25 @ $14.75 for No. 1; $13.25 @ $13.75 for No. 2 and No. 1 Soft.

The Pig Iron business in the Philadelphia market is dull and prices are less firm than they were a week ago. They are not quotably lower, but there is more pressure to sell, and buyers are conscious of the fact that the market is in their favor. Under such conditions they are less disposed to make bids, or when they do make them they are at lower figures than before, and in some cases such bids have been promptly accepted. The general situation is such that we cannot fairly change the list of quotations, because there has not been enough done to warrant it, and, besides, there is a great deal of business being done at former prices. Some furnaces are in fact so well sold up that they have no need to change their figures, no matter what others may do. All the same, any large consumer with money in hand can buy almost any grade of Iron he wants, Bessemer excepted, at fractionally lower prices than would have been considered last week or the week before. The reason for this is due to the fact that Iron "for Iron" is in excess of the demand, Steel having completely usurped the place of Iron. Comparatively speaking, there is no demand for Mill Irons, so that prices must of necessity weaken. Instead of buying 300 to 500 or 1,000 tons of Pig Iron per week, rolling mills buy Steel Billets, and there is no prospect that they will go back to the old method of puddling. With this fact so constantly in view, producers seem to have made up their minds to a long period of low prices, and are therefore disposed to either get cost down to meet the requirements of the market, or to go out of business. It is no use contending against the inevitable, so that during the next few months the contest is likely to be settled on either of the lines indicated. Hence, for the next two or three months, there is little upon which to base expectations of improvement in prices, while there is a possibility that even the present low figures may be still further shaded before a reaction sets in. Meanwhile asking prices are nominally as follows for Philadelphia and equivalent deliveries, with 25¢ to 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore :

American Scotch, No. 1X.....	$16.75	@ $17 00
American Scotch, No. 2X.....	15 75	@ 16.00

From Chicago we learn that the advance in price made last week on No. 1 Local Coke Iron has been maintained and sales have been made in fair quantities, which justifies the action of the manufacturers in endeavoring to get better rates. Business in this class of Iron has been only moderate, it is true, but sellers report a continued accession to the ranks of buyers from unexpected quarters. Many consumers who have already bought are still adding to their purchases and encouragement is felt in the continuance of a satisfactory volume of trade. The local railroads last week for the first time recognized the justice of the claims made by furnacemen here for lower freight rates in competition with Southern Iron. A reduction has been ordered on freight rates from Chicago to Mississippi River points of 50¢ ℔ ton. This is expected to open to local makers an increased territory of considerable proportions unless the Southern furnacemen are able to secure a corresponding reduction in freight rates to the same locality. This remains to be seen. Southern Coke Iron has been sold only to a moderate extent, although inquiries are quite abundant. The Southern companies are generally not willing to make the deliveries that buyers ask; sales therefore are for reasonably prompt shipment. Competition is keen on this class

of trade, but a reduction in our quotations hardly seems advisable under the circumstances. Lake Superior Charcoal is still quiet, but held firmly by producers. We revise our quotations as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50 @ $17.00
Local Coke Foundry, No. 1	13.75 @ 14.25
Local Coke Foundry, No. 2	13.00 @ 13.25
Local Coke Foundry, No. 3	12.75 @ 13.00

In Southern markets there has been a moderate volume of business in Pig Iron during the week, the demand being mainly for immediate or short forward delivery, no sale being reported exceeding 1000 tons, and only a few of this quantity. Buyers decline to purchase for more than three or four months ahead, for they believe that Iron will be no higher; and while there is no urgency to sell for long delivery, the evidences are that purchases could be made for all this year on the basis of current prices. The large Iron companies in the South are doubtless maintaining prices having refused $8, f.o.b. Birmingham, this week for Gray Forge; but it is well known that sales have been made by other parties on this basis. There is little Mottled Neutral Coke Iron offered; but that sympathizes with Gray Forge in weakness. There has been no movement in Charcoal Iron, and, while the market appears to be weak, quotations are nominally unchanged.

Foundry.

Southern Coke, No. 1	$13.25 @ $13.50
Southern Coke, No. 2	12.00 @ 12.25
Southern Coke, No. 3	11.25 @ 11.50
Ohio Soft Stone Coal, No. 1	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2	15.00 @ 15.25
Mahoning and Shenango Valley	14.75 @ 15.00
Hanging Rock Charcoal, No. 1	19.00 @ 19.25
Hanging Rock Charcoal, No. 2	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @ 14.75

Metal Market.

Copper.—The expected spring season active demand is thus far slow to materialize. Evidence is not wanting that considerable quantities of Copper are being used for electrical purposes and that quite the average amount of stock is passing into other channels of consumption. It is a matter of record that production is being kept within manageable bounds. Still there seems to be more supply than demand at the present time and more or less weak undertone to prices, particularly for deliveries immediately after the opening of navigation. It is no difficult matter to fill orders for Lake Superior Ingot at 11¼¢, and hardly any secrecy is attached to the fact that 10¾¢ has only to be bid to find sellers of casting brands. In short, the market presents a weary appearance, despite all the efforts made recently with a view to regulating the relation of supply and demand, so as to prevent values from depreciating. Surface appearances are that Copper, like nearly all other merchandise, is affected to greater or lesser extent by the stringency in the money market.

Pig Tin.—The "bull" interest in the market has spared neither time nor trouble to induce consumers and distributors to believe that Tin is a good purchase at current prices. In fact, all sort of argument has been brought forward to hide the significance of present heavy supplies and large shipments from primary sources of supply during the first half of the month as an offset to the proposed duty of 4¢ ℔ lb. prescribed in the McKinley Tariff law. The fact that future deliveries have been sold in London at a large discount while commanding more or less premium here is also treated with indifference by prominent operators. In short, all signs point to clever manipulation with a view to holding prices, so as to facilitate the unloading of speculative holdings on this side of the Atlantic. Speculative deals have been chiefly at prices on the basis of 21¢ @ 21.10¢ for near future deliveries, and ordinary jobbing sales have in not a few instances been made at prices very close thereto. In futures the local transactions have been moderate, with latest dealings at prices closely in line with those that ruled a week ago. There were sales on Wednesday of 100 tons for May delivery at 21.05¢. April was offered at 20.95¢, but spot quotations were kept at about 21.05¢ @ 21.10¢.

Pig Lead.—Upward of 1200 tons have been sold during the past week at 3.95¢ @ 4¢, delivered, near future shipment. The purchases were chiefly by large consumers, some of whom, to all accounts, have been forced to enter the market to secure ordinary supplies. Light stocks in the West and moderate supplies elsewhere have served to stiffen the market, however, sufficiently to bring prices up to 4¢ bid for carload and larger lots for early delivery. Single carloads realized 4.05¢ on Wednesday, and that price was subsequently refused. At the close 4.10¢ was generally asked.

Spelter.—The market for Western Spelter is somewhat firmer, chiefly under the influence of higher prices for ores and preliminary movement in the direction of formation of a combination of producers. Buyers in this quarter and vicinity are not perceptibly influenced, however, and the market remains in a dull condition. For the present any price under 4.30¢ for near future shipments would appear to be exceptionally low, and for spot parcels 4.35¢ is named as a close price.

Antimony.—The market is still somewhat unsettled, but prices have undergone no decided change. Current quotations are 10¢ @ 10½¢ for Hallett's, 10½¢ @ 10¾¢ for LX and 10¾¢ @ 10¾¢ for Cookson's.

Tin Plate.—Business has been rather slow and the market bare of really new feature. Arrivals have been quite heavy, but the greater portion went in delivery on old orders, and, in the absence of any radical change in the foreign market, prices here remain very steady. The retail demand for Tin Plate is small, particularly in Ternes. Wasters are difficult to obtain on account of a limited supply. Although ocean freights on Plates have recently advanced, no increase in prices is contemplated in the near future.

Coal.

The effect of the recent advance in the prices of Anthracite Coal is to excite general inquiry with reference to future supplies. Thoughts are turned in the same direction by the prospect that increased demands for transportation will follow the opening of interior navigation, and the West will naturally be on the alert to provide for future wants before the World's Fair opening, and consequent demand for cars interfere with ordinary traffic. Prices are steady, except as they may be affected by a reported cut on the part of independent companies, who are said to be scooping in more business. As a rule, however, trade is flat. Of course there is a liberal movement of Coal for consumption, when considered in the aggregate, and some operators are short of special sizes. Pea and Buckwheat are still scarce; Pea, $2.50 @ $2.75, and Buckwheat, $2.50 @ $2.15, f.o.b. Stocks at all distributing points are of moderate proportions. Week's production, 863,707 tons; total to date, 7,531,571 tons, against 7,355,090 tons last year. Reading tonnage, 410,000 tons. Reading Railroad's Bituminous tonnage, 323,882 tons; Coke, 121,997 tons. Stocks at Port Richmond and New York, 467,000 tons; at Buffalo and Chicago, 460,000 tons. Bituminous shipments are heavy, under an improving demand. Clearfield for the week, 69,882 tons; Beech Creek, 69,888 tons; Chesapeake and Ohio, 74,381 tons; Norfolk and Western, 65,422 tons. Coke shipments for the week, 120,000 tons. Prices are unchanged.

It is reported that a number of suits are about to be brought against the Delaware, Lackawanna & Western Railroad for overpaid freight charges for Coal tolls. About a year ago the Lackawanna adopted the 60 % basis for purchasing Coal from individual operators, but, it is said, neglected to make a corresponding reduction in transportation rates. Individual operators who marketed their own Coal were therefore compelled to pay the maximum freight rate, which some of them did under protest.

Financial.

The New York money market, one might suppose, from the accounts colored by Wall street speculators, is in a strained and unnatural condition entailing much hardships among the mercantile classes. A bank president, who is in close touch with merchants and traders, remarks that this is an erroneous view; that, in truth, the experience this season in regard to discounts, accommodation, &c., is much like that of other seasons when money is wanted over a wide range of country for moving crops. The banks are accommodating their customers about as usual, of course, looking well to their securities. Doubtless there is far more difficulty of late in disposing of paper through brokers, who are unable to command the ample facilities sometimes enjoyed. The wants of the Treasury Department and the demand for export, tend to exhaust the gold resources, but bankers generally seem to think that the bottom has been touched, so that the proposed issue of Government bonds may be long deferred, or become altogether

unnecessary. Increased confidence abroad may cause a renewed demand for American securities, and exports of produce on the opening of navigation will be augumented. Still, the fact cannot be ignored that in our foreign trade there exists an adverse balance amounting to $32,000,000, as compared with a favorable balance of $171,000,000 one year ago. On the other hand, the quantity both of wheat and grain available for export is extraordinary; but, unfortunately, the price of wheat is about the lowest ever known. A question of much significance at the present time relates to the probable foreign demand for these articles, even at a concession from present market quotations. To carry these commodities requires a large amount of money.

Stocks have been irregular, influenced by railroad troubles at the West, dear money, and reports concerning the coal trade. The statement that Reading had 1,100,000 tons of coal among its active assets was regarded as a menace to the coal market. Erie was especially weak on sales by foreign houses. Saturday's bank statement had little influence, it being apparent that the gain in surplus was due to a contraction in loans.

General trade is on a conservative basis, and without speculation. Goods of the coarser description will, in many instances, be held back for the opening of navigation. Wheat, after various fluctuations, was a fraction higher at the close. In flour on Monday there was more firmness than for some time past, and exporters took hold with alacrity. Provisions are again lower.

A review of the foreign commerce of the United States for February shows an increase of over $13,000,000 in the imports, and in spite of the large shipments of specie, a decrease of more than $18,000,000 in the exports, making a difference in the balance of trade for a single month of nearly $32,000,000. Last year the February exports exceeded the imports more than $26,000,000; this year the February imports exceeded the exports, leaving out the specie from both totals, $19,688,262, showing a change in one month of over $40,000,000.

Chicago Report.

Scrap.—The market has undergone no change in the past week. Dealers' buying prices are as follows:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....

CONDITION OF THE

Hardware Trade.

THE PAST WEEK has given little change in the general condition of the Hardware market. Trade on the whole is in excellent volume, and shows a natural increase as the season advances. In a good many lines the manufacturers are fully occupied on orders, and in some are unable to turn out the goods as rapidly as called for by their customers. In the matter of prices the market is at least in as good condition as it has been for several weeks, and in some lines there are indications of improvement. Collections are not entirely satisfactory, and complaint is made of difficulty in making them in several parts of the country.

Advices from Chicago.—Shelf Hardware orders came in something like an avalanche last week, following a few days of comparatively pleasant spring weather. The orders now received are running considerably larger than usual, showing that merchants generally are stocking up on account of the spring demand from their customers. Heavy Hardware is moving freely, all branches feeling an improvement in the trade consequent upon a belief in the genuine advent of spring. The month of March is coming up to its usual record for heavy business. Collections are still slow, probably not more than one-half what they should be at this season.

Notes on Prices.

Cut Nails.—The Cut-Nail market is represented by the quotation of $1.20 to $1.25 for carload lots at mill, the former figure being readily obtainable, though the latter is quoted in some cases. The new card is used by all the mills and is regarded as quite satisfactory. There are, however, indications of a tendency on the part of manufacturers to shade quotations slightly on specifications with a high average. The figures named above are generally quoted on assortments without regard to average. Carload lots on dock are regularly quoted at $1.40, with the usual advance for small lots from store.

Advices from Chicago.—The trade in Cut-Steel Nails has felt the effect of better building weather in the steadily increasing business every day for the past week. Prices are unchanged at $1.42½, Chicago, for mill shipment on the basis of the new card. Everything is moving smoothly under the new arrangement, and outside manufacturers appear to be standing by the schedule of prices previously published. Small lots are selling from stock at $1.50.

Wire Nails.—The Wire-Nail market continues in a very satisfactory condition and prices are evenly maintained. Notwithstanding the advances which have taken place, manufacturers report an excellent demand and many inquiries, so that the aggregate of current business is satisfactory. The market is characterized by an even and firm tone, and it would appear that Nails required in the near future are regarded as a safe purchase at current quotations, which are on a basis of $1.50, f.o.b. factory, Cleveland being the point of equalization for the West and Pittsburgh for the East. Small lots from store in New York are quoted at $1.75 to $1.80.

Advices from Chicago.—Manufacturers of Wire Nails state that the demand from jobbers is now excellent for delivery during the coming three months. The situation from the manufacturers' standpoint is steadily growing better. They have been able to maintain the advanced price without a break and look forward to a higher price if the present heavy consumption continues for the length of time expected. A conservative feeling obtains, however, with regard to making advances, and no further step in that direction will be taken until every condition is seen to fully warrant it. Quotations continue at $1.65, Chicago, for mill shipment. Jobbers report unchanged prices of $1.70 from stock and $1.65 for carloads.

Barb Wire.—While there has been no formal change in the quotations for Barb Wire, the market is somewhat firmer, so that $2.45 may be regarded as the price for carload lots of Four-Point Galvanized at mill. The volume of business is excellent and manufacturers are anticipating a heavy trade during the season, the prospects for a large consumption being unusually bright. Carload lots on dock in New York are quoted at $2.65 to $2.70. There has been no change in the price of small lots from store.

Advices from Chicago.—Contrary to expectations the Barb-Wire manufacturers concluded not to advance prices, at the meeting which was in session last week when our report was written. The conditions, it was then believed, were then propitious for an advance in prices, but jobbers had been so generally supplied with Wire at low rates, that an advance by manufacturers would probably have confined the trade for some time to jobbers and prevent manufacturers from obtaining any advantage from it. It was, therefore, decided to postpone any change in prices until some time in the future.

Meanwhile, the demand continues very heavy and large shipments are now going forward. Factory prices are reported at $2.20 for painted and $2.60 for galvanized. Jobbers quote small lots at $2 25 and $2 65 respectively.

Wrought-Iron Pipe.— The Wrought Iron Pipe market is weak and demoralized and prices are extremely low, notwithstanding the fact that the demand is good and the volume of business large. There are at present no definite indications of an understanding being reached by the manufacturers with a view to advancing prices, but it is not thought likely that the present condition of things can be of very long duration.

Cordage.—The advance referred to in our last issue in the price of Sisal Rope has been followed by a slight advance in Manila. The strength of the market is owing to the higher prices which are ruling for the raw material. The present condition of the market is represented by the following quotations for round lots, f.o.b. factory, subject only to a discount of 1½ per cent. for cash:

	Base.
Manila	9½ cents.
Sisal	7½ "
New Zealand	6¾ "

Montgomery's Patent Hammer.—This Hammer is put on the market by Montgomery & Horton, 107 Chambers street, New York. Only No. 1½, 1 pound, is at present made. It is listed at $12 per dozen, subject to a discount of 40 and 10 per cent.

Furnace Fittings.—The Excelsior Steel Furnace Company, 110 to 114 South Jefferson street, Chicago, are manufacturers of fittings for hot-air furnaces, with which they are now supplying the trade generally. Special machinery of an expensive character and requiring extended and costly experiments has been devised for their purposes. These goods are now recognized as staples, and we therefore take pleasure in printing the following price-list, on which there is a trade discount of 50 per cent.

Screen Door Pulls, No. 1151	1.10
" " " " 1152	1.50

Glass.—The Glass market remains practically unchanged since our report last week. Business with jobbers and importers is quiet and but a limited amount of Glass is changing hands. Manufacturers of American Glass report a good demand and that the tendency is toward further improvement in this direction. It is also stated that manufacturers do not succeed in accumulating any large stocks and that it is not probable that they will be able to do so before the season closes. It is intimated that prices will be advanced in the near future by the National Window Glass Company, and also that the United Glass Company have joined the National Company. Since the arrangement of having all orders for Plate Glass pass through the hands of a general agent went into effect, this branch of the Glass business has been in a much more satisfactory condition. Stocks are reported as considerably smaller than a year ago, with a good demand and stiffer prices than for a year past. The New York importers of Glass are still formulating a plan for regulating prices, and, while no official announcement has been made, it is understood that a forfeit, to be paid in case agreed prices are cut, will be a feature of the agreement. Quotations remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

The Cut-Nail Card.

THE FOLLOWING LETTER from a well-known Cut-Nail manufacturer will be of interest as referring to the relations of Cut Nails and Wire Nails as they are affected by the recent action of the Cut-Nail makers in adopting the Wire-Nail card:

To the Editor: It is a little remarkable that no one has explained the real cause for the adoption of the Wire-Nail card by the Cut-Nail manufacturers, in all the criticisms, favorable and otherwise, in your columns.

It was adopted simply in order to flank a brilliant move of the Wire Nail manufacturers. The latter gentlemen have but a very limited trade in Nails larger than 10d. To make a low price for the large Nails would cost them little, since they sold few of them.

To the Cut-Nail manufacturers, on the other hand, the price of the large Nails is important, for these Nails are largely used, by preference, over Wire Nails in heavy work requiring strength and powerful cohesion.

The Wire-Nail manufacturers made a low price for 60d Nails, for which they had little demand, and they advanced the price 50 cents per keg on 10d, and correspondingly on all the smaller sizes. They could thus quote a low base price for use in market reports, and yet get good prices for their average assortment. The Cut-Nail makers charge but 20 cents per keg extra for their 10d. If they made a low base price for 60d, their 10d also would sell below cost. Consequently they were at a disadvantage. The market quotations being for base size only, brought trade to the Wire-Nail manufacturers. In adopting the Wire-Nail card, for Nails sold in fair assortment, and in charging 10d price for all large Nails when sold alone, the Cut-Nail manufacturers have met the situation. The base prices now quoted fairly represent the actual difference to the purchasers of assorted Nails between Wire Nails and Cut Nails. The latter are cheaper by 25 cents per keg, and the market reports show it, as they should.

To charge 50 cents per keg more for 10d than for 60d is, of course, ridiculous, and every manufacturer of Cut Nails or Wire Nails freely admits it. To make 60d Nails at the quoted prices is an impossibility.

The Wire-Nail card (exactly imitated by the Cut-Nail card) is an absurdity, and no manufacturer pretends to defend it upon its merits.

But it is the Wire-Nail manufacturers that are responsible for this card. They introduced it, and if they will change it their action will be quickly followed by the Cut Nail manufacturers. So long as they retain it the Cut-Nail manufacturers will do the same.

If, therefore, any Hardwaremen are dissatisfied with it, it is to the Wire-Nail manufacturers that they must address their complaints and criticisms.

CUT-NAIL MANUFACTURER.

Trade Notes.

STARK MACHINE & TOOL COMPANY, Buffalo, N. Y., are just finishing a complete outfit for the Victoria Mfg. Company, Fort Erie, Ontario, for manufacturing the Ehle Nestable Dinner Pail in Canada. Messrs. Stark inform us that the outfit consists of about 125 drawing, cutting, combination and wiring dies, and six presses of various sizes. It is expected that the plant when finished will be one of the most complete of its kind.

THE ECLIPSE MACHINE COMPANY, Troy, N. Y., in an advertisement elsewhere, make an announcement of interest to tin and cornice shops respecting machines of their manufacture.

THE INDIANA LADDER COMPANY, Indiana, Pa., call attention to the Bent-Rung Ladder of their manufacture, and refer to its value for tinners, painters, builders and others.

A SPECIAL NOTICE of Haydock & Bissell calls attention to an auction sale to take place Wednesday and Thursday,

March 29 and 30, at 12 Murray street and 15 Park Place, New York City. A list of goods to be sold is given and includes a variety of Knives and Forks, Scissors, Silver-plated Ware, Ladles, Spoons, Pocket Knives, Razor Strops and other goods.

C. A. Cornell and N. E. Church, two enterprising young men of Troy, N. Y., have formed a copartnership under the firm name of Cornell & Church to carry on the business of metal and electroplating. They will have an office and shop on Ida Hill, near Troy.

Paul Thomas, manufacturing chemist, Richard and Delevan streets, Brooklyn, N. Y., distributes a circular relating to his Concentrated Soldering Flux. This Flux, it is said, makes no poisonous fumes, does not discolor or stain material, contains no free acids, does not injure tools or hands, is absolutely non poisonous, besides possessing other advantages. A list of references and several testimonial letters are printed in the circular.

Murphy Brothers of Lynchburg, Ohio, have succeeded the firm of H. Murphy & Son of same place.

The United States Iron & Tin-Plate Mfg. Company of Demmler, Pa., have awarded the contract to the Heine Boiler Company of St. Louis, Mo., through their Pittsburgh office, for four 100 horse-power boilers, to be placed over their heating and puddling furnaces.

In their advertisement appearing elsewhere in this issue, the Pittsburgh Tin-Plate Works, New Kensington, Pa., direct attention to their different brands of American Roofing Tin, known as Kensington, Westmoreland and Juno. The makers state that these Plates are made by the palm-oil process only, no acid being used in the coating. The names of agencies are also given in the advertisement from whom these brands of Plates can be secured.

In their advertisement appearing elsewhere in this issue, John W. Bell & Sons, Mercer, Pa., direct attention of the trade to their Wire Eave-Trough Hanger. The concern advise us that the demand for these Hangers is constantly increasing, large shipments having recently been made to Louisville, Cincinnati and other large cities. In addition to the above, this concern manufacture Bell's Lawn Grass Collector, concerning which full information will be furnished by the firm upon application.

Summers Brothers & Co. of Struthers, Ohio, manufacturers of Box Annealed Sheet Iron and Sheet Steel, will build another sheet mill this summer, having already started to put up the boilers and shears. The rolls will be 24 x 42 inches in size, made especially for rolling light Steel Sheets. The plant of the above concern is being operated full time, with plenty of orders on hand.

The McLeod & Henry Company of Troy, N. Y., circulate a postal card upon the back of which is a general view of their special lining fire-brick works at Troy. The foreground of the picture is humorous in its nature and bears beneath it a request for quotations.

Illinois Pure Aluminum Company, Lemont, Ill., are now preparing to make a Pan of any size to displace copper Pans used in large kitchens of hotels, steamers and restaurants. They are making a Pan for hotel use, 9¾ inches in diameter, and 1¼ inches deep inside, which, it is stated, weighs 1¼ pounds in aluminum, in comparison with a copper Pan of similar capacity weighing 14½ pounds. The point is made that the price, taking into consideration the constant retinning requisite for the copper utensil, makes the cost in favor of aluminum.

We understand a decision of the suit for infringement of Waffle Iron patent brought by the Griswold Mfg. Company, against J. B. Harker & Co. and others, will be decided early in April by the United States Court at Minneapolis. The decision will be awaited with interest.

Geo. N. Pierce & Co., Buffalo, N. Y., manufacturers of Refrigerators, Bicycles, Tricycles and Bird Cages, have opened a New York office at 23 Warren street, where a stock of the goods will be carried.

The Mackinaw Refrigerator Company, New York office, 106 Chambers street, in issuing an illustrated pamphlet of these goods, direct attention especially to some of the more recent additions to the line which are referred to as meeting with considerable favor, being made in very tall or very broad patterns for special uses, among them being Nos. 197, 199, 275, 4120 and 1000. We are advised the trade in this make of Refrigerators has doubled lately. The goods for some time past have been quoted net from this office, and the results are alluded to as very satisfactory, a departure having been made in the method of doing this expeditiously, resulting in the preparation of a special circular, which leaves but little to add in sending prices on application, a copy of which is kept with little labor.

The entire plant of the Youngstown Stamping Company, Youngstown, Ohio, has been put in operation, with the exception of the Glass factory, which is expected to be working within a very short time. This concern reports a large accumulation of orders with the prospects of a heavy demand for their line of Oil Cans, Tin Specialties, &c., during the spring and summer. Some improvements have been made in their factory, which will allow them to turn out a considerably larger quantity of Tin Fruit Cans during the coming season, for which this concern have a very large demand. As before announced, the entire plant will be operated under the management of W. C. Hine, receiver.

The Novelty Stamping Co. who have been recently organized at Bellaire, Ohio, will manufacture Stamped Ware and all kinds of Sheet Metal specialties. The buildings comprising their plant are all new, and fitted up with the most improved machinery for their line of manufacture. The company are not yet in full operation owing to the fact that their dies are not completed. When they are, employment will be given to some 200 persons. The officers of the company are M. L. Blackburn, president and general manager; A. Klotz, vice-president, and W. C. Bergundthal, secretary and treasurer.

The party of American manufacturers who have recently made a tour through Mexico with a view to examining the condition of that country and its commercial capabilities, returned home this week with favorable reports. They appear to have thoroughly inspected the principal Mexican seats of industry, and were everywhere cordially received. A correspondent in the City of Mexico, writing recently to a Southern trade journal, said: "The excursion of manufacturers from the United States arrived in the City of Mexico on February 14, and after spending some days in examining the important manufacturing establishments, factories and points of interest in the city, went to Vera Cruz, where various establishments and manufacturing interests were seen. The party have expressed themselves as surprised at the excellent opportunity for trade which exists in Mexico, and it is expected that the trip will result in a strong effort to introduce American goods." As a proof of the impetus which has recently been given to business in the Republic, it is stated that during the past year 59 new companies have been organized for operation in Mexico, all of which are either American or English enterprises. Of these companies the United States has furnished 50, with an aggregated capital of $91,625,000, the remainder being English, with $8,000,000 capital.

BRITISH AGENCY: The Ironmonger, 42 Cannon St., London, England.

The Cleveland office of *The Metal Worker*, under the management of Ezra S. Adams, removes on April 1, from 219 Superior Street to Room 312 of the Cuyahoga Building, Cleveland's latest addition to its modern business structures.

The British Tin-Plate Industry.

A tabular statement showing the exports of tin and terne plates from Great Britain from 1862 to 1892, inclusive, has just been issued by Bradley & Burch of London. The statement shows a remarkable development of the British tin-plate industry during that period. The total exports in 1862 reached 1,000,437 hundredweight. In 1892 they were 7,911,600 hundredweight. The shipments of the previous year, however, were the highest on record—namely, 8,967,580 hundredweight. During all these 30 years the United States took by far the greater proportion of the British tin plate exported. In 1891, 6,502,860 hundredweight, or more than four-fifths of the total exports, were shipped to this country. Last year this proportion was somewhat reduced, being 5,569,580 out of a total volume of 7,911,600 hundredweight of exports. It is shown in these tables that the home consumption of tin plate in Great Britain has grown in the last eight years from 1,750,000 to 2,600,000 hundredweight. There are now in England and Wales, it is stated, 100 tin-plate works in existence, comprising 509 mills; and of these mills 409 are in operation, with an estimated productive capacity of 10,500,000 hundredweight per annum. In view of these facts and figures, it is small wonder that British manufacturers of tin and terne plates view with apprehension the growth of the industry in this country.

Disappointments in Promotion.

One of the most galling things that happen to a man in business or industrial life is to be passed over in promotion. An employee, after faithful and long service in a subordinate position, sees a place in his business on which his eye has been fixed for years in the hope and expectation that he shall one day fill it, at last fall vacant. He thinks the fullness of time has come and that his hopes are at length to be realized. But, to his mortification, a junior or an outsider is preferred for the post. He immediately concludes that he is the victim of gross injustice; and, if he is what is called a "high-spirited" fellow, he throws up his job in a fit of pique and goes forth to seek new employment, sacrificing a steady and assured position and all the claims of his faithful service for the gratification of his injured vanity. He fails to consider that the fact of his not having been awarded the special place he wished for gives him the greater claim on his employers when another opening for promotion occurs. And the worst of it is that he usually finds sympathetic friends to condole with him and applaud his "proper pride," causing him to metaphorically pat himself on the back as a fine fellow who will brook no slights. Whereas he is actually more aptly to be compared to a pettish child who refuses all its dinner, though hungry, because it is denied some special dish which its wiser parent for good reasons withholds. Sometimes, we admit, the method of filling places by employers is grossly unjust, and when that is clearly seen and maturely considered, it is, perhaps, justifiable for a man to seek employment where his qualities and abilities will be more appreciated.

Promotion by Merit.

But we are inclined to believe that injustice does not mark the majority of cases where men are passed over in promotion. Usually it will be found that the overlooked clerk or workman, although believing himself to be competent to fill the coveted post, is not considered by his superiors to be equal to its duties. Men are by no means always the best judges of their own ability. The "boss," or member of the firm with whom the nomination lies, has generally had his eye on the men who may be candidates for positions of responsibility, and knows which is the best one for the place. One rule is pretty constantly followed by employers in promoting their subalterns, and that is that the best man is the one who will fill a post to the best interests of the business. It is unlikely that an interior man will knowingly be preferred. It would be contrary to the employer's own interests. Therefore, in such a case as we have put, it is well for the disappointed individual to weigh well the probable reasons for the apparent neglect of his claims before taking hasty action. Let him not get a "big head," and think the business cannot get along without his services, and either throw up his position altogether, or go along sulkily determining that in future he will not put himself out to do any more than is absolutely necessary. Rather let him in a manly spirit face his disappointment and resolve that if merit is to win the next promotion he will be the man to get it. In nine cases out of ten evidence of such a spirit and disposition, combined with diligence and ability, will be the most effective testimony to the employer of the man's fitness for a rise. He will say:—"We can't pass over so-and-so this time. He took his last set-back so well, and has, it anything, been more useful since, that he is the man for this place." Patience and merit are bound to win in any line of life provided they have the necessary dash of push and energy indispensable in the present age.

The Lowest Bid in Plumbing Contracts.

The practice of awarding contracts for plumbing work in buildings to the lowest bidder is something which in the light of experience needs consideration. In theory it may be correct because of the natural assumption that no man will knowingly offer to do work at less than it will cost him. But architects are wiser, and their experience in this regard has impressed many of them, at least, with the conviction that it would be cheaper, all things considered, to give the contract to the man whose bid more nearly approaches the correct amount than to the inexperienced man who has not the knowledge to cover every possible detail of outlay in his estimate for the job. This is readily accounted for. From time to time young men, ambitious to be master plumbers, go into business on their own account with a proper knowledge of their trade as mechanics, but totally at sea as regards business knowledge, the cost of material and labor and the necessity that the work be not delayed. They put in bids for plumbing contracts at as low a figure as they consider will cut out the old well-established plumbers, and in the existing order of things obtain the contract. After the work is well under way, the enterprising contractor finds out that he has undertaken too much, and, being unable to grapple with the difficulties of the situation through lack of experience and resources, finds when it is too late that he has gone beyond his depth and cannot keep pace with the work as required.

Costly Delays.

As a consequence the plasterer, the carpenter and the concrete men are at a standstill, for, until the plumber's work is done, the walls cannot be finished, the casing of pipes by the carpenter cannot be done, and the concrete man in the cellar is vainly waiting for the house drain to be laid. The owner is likely to find out also that the economy which prompted him to accept the "lowest bid" was not a wise one, that it was a case of "tight at the spigot and loose at the bung," and when, in the case of a tenement building, he is deprived of at least a month's rent by the delay of the plumbing work, he finds out that time is money and that there is nothing saved.

whatever is lost, by giving his plumbing contract under all the circumstances to the cheapest man. But while this is the owner's side of the question, the competing plumber has also to be heard. His experience of the "lowest bid" business is in his own way unfortunate. The architect sends out requests to plumbers to estimate for certain work. Four or five or more plumbers will make estimates in good faith in the expectation that the contract will be given to the lowest bidder. It may be, however, that the architect may desire to give the contract to some favored plumber whose estimate is in the first instance too high. The competing estimates being lower, the architect has only to say to the preferred plumber, "The contract will be yours if you come down to these figures," to which in most cases he consents. The contract is awarded him, while the plumbers who have enabled the architect to bring his friend down to the required amount have nothing for their pains beyond the consciousness of being made the instruments by which another plumber is influenced to take the contract at a reduced estimate. The awarding of plumbing contracts to the lowest bidders does not always yield unmixed satisfaction to those interested.

Chicago's Manufactures.

We have commented to some extent at various times on the rapid development of manufacturing towns in the vicinity of Chicago, either within the corporate limits of the city or a very short distance outside. This movement has by no means culminated, but still continues, being remarkably persistent. It has covered more than an ordinary business cycle since it became sufficiently pronounced to attract much attention. Booms in other localities have run their course and faded, but new Chicago projects continue to come forward. Several ambitious schemes, with industrial enterprises of promising scope as a nucleus, have quite recently been organized and will shortly be launched on the sea of popular favor. It seems only reasonable to suppose that a limit of development of this character must be reached, but thus far all predictions of a disastrous collapse have failed.

Consumption of Wire Rope.

A surprising quantity of wire rope is used in the operation of elevators in office buildings and warehouses. In a seven-story office building, for instance, in which there are only two elevators, nearly a mile of one-inch wire rope is required for the elevator equipment. It can readily be seen from this statement that the consumption of wire rope for this purpose alone throughout the country is enormous. The construction of very large office buildings above four stories in hight is of comparatively recent date, the movement being scarcely ten years old. In fact, there are not a few important cities in which construction of this character has but just begun. It is probable that already the consumption of wire rope for passenger and freight elevators in buildings is as large as in any other single channel. This is but one of the numerous developments of business enterprise which is steadily increasing the general consumption of iron and steel.

Malleable Castings.

The malleable iron foundries have increased their capacity remarkably during the past year or two. Not only have old concerns, almost without exception, greatly enlarged their facilities, but a number of new establishments have been started, and all appear to have plenty of business, although the usual complaint is heard in this as in all other branches of manufacture that profits are reduced to almost nothing. The growth of this trade is due mainly to the expansion of the business of agricultural implement manufacturers, who are heavy purchasers of malleable castings. But the consumption of malleables has also increased in many other directions, and large establishments are to be found that do not to any considerable extent depend on the agricultural trade for their business. The growth of the manufacture of small wares, in almost infinite variety, is proceeding at a rapid rate, and for many of these malleable castings are demanded.

Makers of coke pig iron have found this an inviting field for their attention, and they are attacking with considerable success this last stronghold of charcoal iron, which has hitherto been deemed indispensable for malleable castings. Special qualities of coke pig iron are being made for this purpose, and it is asserted that the percentage of coke iron used has not reached its limit. The aid of chemistry has been invoked in this as in other branches of the pig-iron trade, and some aggressive coke-iron makers claim that they can now furnish material totally innocent of charcoal which will make high-grade malleable castings.

Shop Stories.

THE SCOTCH PLUMBER AND HIS BOOK-KEEPER.

In a thriving Canadian town there resides an industrious son of the Land O'Cakes, who for more than "Sax an' twenty simmers ha seen the bud upo' the timmer" since he hung out his sign, "Robert Douglas, Sanitary Plumber."

His reputation for doing good work at honest prices has failed to yield more than a plain, humble living for a constantly increasing family. His infant industries have apparently been his only prosperous ones. Recently his eldest son, having completed his schooling and apprenticeship, was admitted a partner in business with his father. The son's education had been extended to the science of accounts, but his skill in this had not been as well tested as his knowledge of plumbing.

When the sign had been enlarged to read "Robert Douglas & Son," Jack, the son, took charge of the books. At the end of the first year he prepared a statement of their business, showing a handsome net profit. This "balance sheet" proved a great surprise to the old man. The profits appeared unduly large. Never before had he cleared anything above the actual cost of living. Now something truly startling appeared. In a single year, with his son as partner and bookkeeper, nearly $2000 had been gained. It was actually too good to believe. Jack insisted that his statement was entirely correct, and, moreover, there were the figures to prove it. So the old Scotchman accepted it as true, and quite naturally felt pleased over it. He accordingly decided to enjoy some of the fruits of his honest toil by indulging in more comfortable clothing for his family and self and the purchase of some much needed household goods.

> But pleasures are like poppies spread—
> You seize the flower, the bloom is shed.

And, alas! our old friend's enjoyments proved as short-lived, for when the purchase bills were presented there did not appear to be any more ready cash to pay with than formerly. He did not have the "stuff." Truly here was a mystery. The balance sheet was apparently all right, but where was that $2000 hiding? Determined to solve the riddle he hunted up Jack's statement and declared: "Before I sleep a wink I vow I'll find it."

Long, dreary hours were spent by the old man in his lonely shop searching for the missing funds. He sat up until "the wee sma' hours ayont the twal," while his family slept, innocent of care and ignorant of the earthquake that was about to swallow up their domestic joys. The bills of the "butcher, the baker and the candlestick maker" were large; their demands urgent, and money must be obtained to pay them. Each item is carefully scanned, the footings gone over carefully, but always from the bottom upward. They prove Jack's knowledge of addition to be all right, but do not console the old man in his perplexity. Finally, after several hours of fruitless search, it occurs to him to test the footings from the top downward. And now came a revelation that fairly lifted the old man off his seat, and the discovery of the much lost and long sought item. But, to his dismay, it proves to be something gone forever and that none have ever recalled.

Frenzied with rage, as he realized his embarrassment and the hopelessness of the situation, he hastens upstairs to the room where Jack has been soundly sleeping all these weary hours, oblivious both of the damage his blunder has cost and his father's diligent search. With a rush he seizes the hapless youth and drags the sleeping form from the bed to the floor as he exclaims: "Jock! Ye *skellum* bumler! Ye're nae worth a plack! Ye hae ruin'd me! Ye added in the year of the Lord!"

SWIPED JOINT.

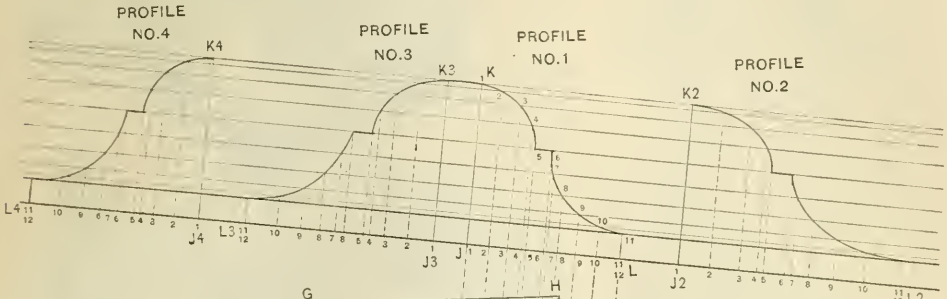
In connection with the new British Labor Bureau, President Mundella of the Board of Trade has sanctioned the employment of 21 labor correspondents in Manchester, Liverpool, Sheffield, Newcastle, Birmingham, and other great trade centers of England. The duty of these correspondents will be to supply periodical information with regard to matters affecting labor in their respective districts. They will communicate with the Central Labor Department, and their reports will be published monthly in the official journal of the Board of Trade.

There were erected in Pittsburgh last year 3,470 buildings at a cost of more than $8,000,000, which is a large increase over any previous year.

THE TIN SHOP.

Pattern for an Article, the Plan of Which is an Irregular Polygon.

From PATTERN CUTTER. *Troy.*—The plan shown in Fig. 1 represents that of a pinnacle required on a certain building The shape in plan is that of an irregular polygon, and supposing each of the sides to be a different shape, the usual method would be to develop a new stay or profile for each. This requires an amount of time out of keeping with the value of the work. As a matter of convenience, a simple molding is given for the profile of the article, and the usual method for obtaining the patterns shown. If there are any readers of *The Metal Worker* who have a shorter solution of the problem than the one shown, I shall be glad to have them present it.



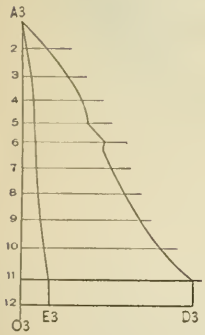


Fig. 2.—Pattern of No. 3.

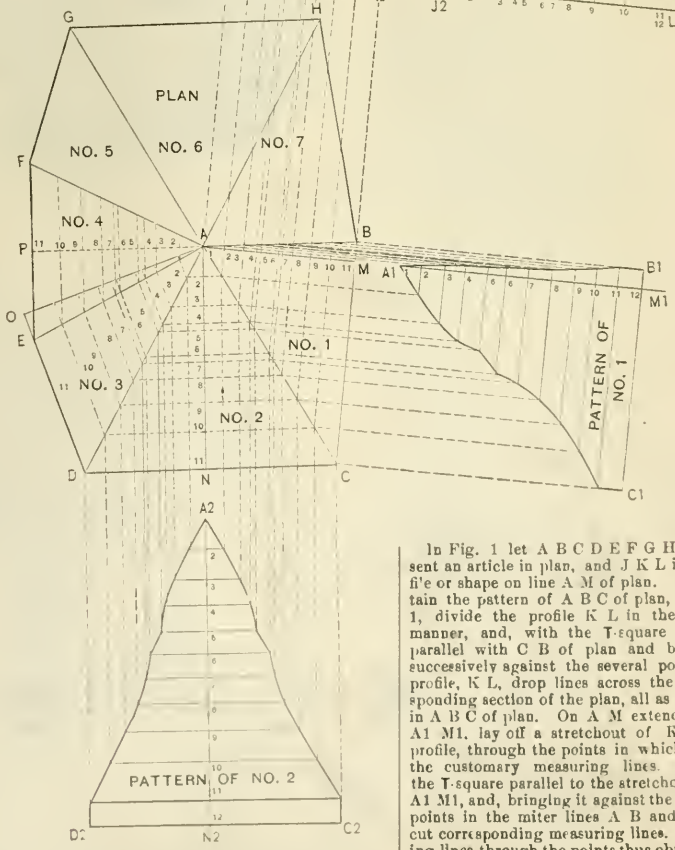

Fig. 1.—Plan, Profile and Patterns.

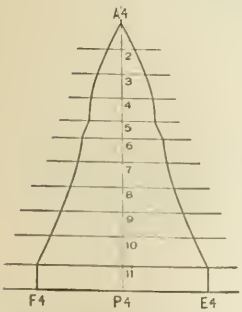

Fig. 3.—Pattern of No. 4.

PATTERN FOR AN ARTICLE THE PLAN OF WHICH IS AN IRREGULAR POLYGON.

In Fig. 1 let A B C D E F G H represent an article in plan, and J K L its profile or shape on line A M of plan. To obtain the pattern of A B C of plan, or No. 1, divide the profile K L in the usual manner, and, with the T-square placed parallel with C B of plan and brought successively against the several points in profile, K L, drop lines across the corresponding section of the plan, all as shown in A B C of plan. On A M extended, as A1 M1, lay off a stretchout of K L of profile, through the points in which draw the customary measuring lines. Place the T-square parallel to the stretchout line A1 M1, and, bringing it against the several points in the miter lines A B and A C, cut corresponding measuring lines. Tracing lines through the points thus obtained, as shown by A1 C1 B1, will give the pattern of part of article shown on plan by A B C.

With the T square placed parallel with D C, and brought successively against the points in A C, draw lines cutting A D.

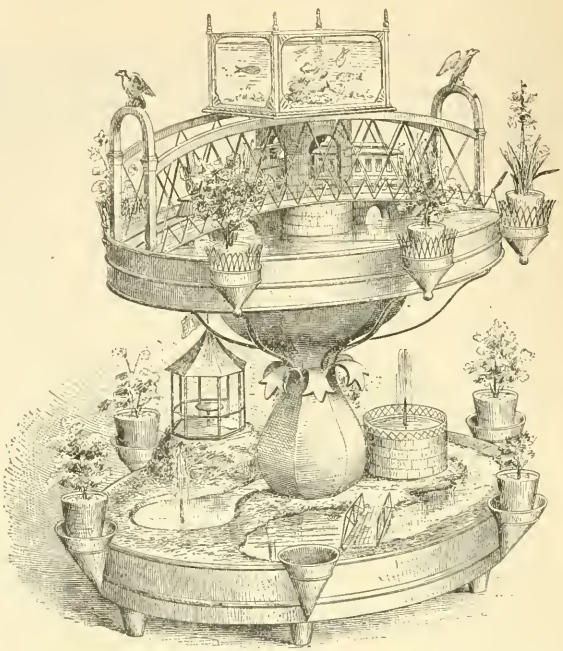
From A, drop A N, perpendicular to D C. Then the points in A N can be used to obtain a profile of section No 2. Also continue the points from A D across the third section of the plan, and parallel with D E, and produce them until they cut A D, which is a line drawn from A at right angles to D O produced. Then A O contains the points necessary in obtaining a profile of the third section. Continue the points from A E across the fourth section of the plan, and parallel with E F, and produce them until they cut A F. From A, drop A P, perpendicular to E F. Then the points in A P can be used to obtain a profile of section No. 4.

Continue J L of profile No. 1 in either direction, as shown by L4 L2 From the several points in profile No. 1 draw lines parallel with L4 L2, extending them indefinitely in either direction. To obtain the profile of No. 2 on line A N of plan proceed as follows : From any convenient point on the base line L4 L2, as J2, set off points corresponding to the points in A N of plan, making the distances from J2 equal those from A of plan. For convenience these points can be numbered to correspond with the points in profile No. 1. From each of the points laid off from J2 erect perpendiculars and continue them until meeting horizontal lines of same number drawn through the profile No. 1. A line traced through these points of intersection, as shown in J2 K2 L2, will complete the profile. The profile of No. 3 is obtained in a similar manner. From J3 set off points corresponding to the points in A O of plan, and from each of the points thus obtained erect perpendiculars, and continue them until they meet horizontal lines of same number drawn through the profile J K L. A line traced through these points of intersection, as shown by K3 L3, will complete the profile. For the profile of No. 4 proceed in a similar manner. From J4 set off points corresponding to the points in A P of plan, and from each of the points thus obtained erect perpendiculars and continue them until they meet horizontal lines of same number drawn through the profile of No. 1. A line traced through these points of intersection, as shown by K4 L4, will complete the profile. If desired the profiles of the other divisions can be obtained in a similar manner.

To obtain the pattern of No. 2, or A C D of plan, proceed as follows: On A N extended, as A2 N2, lay out a stretchout of part of profile K2 L2, through the points in which draw the usual measuring lines. Place the T-square parallel to the stretchout line A2 N2, and, bringing it against the several points in the miter lines D A and A C, cut corresponding measuring lines. Lines traced through the points thus obtained, as shown in A2 C2 D2, will be the pattern of part of article shown on plan by A C D. The pattern of No. 3 can be obtained in the same manner, or as shown in Fig. 2. To do this, draw any line, as O3 A3, on which lay out a stretchout of profile No. 3. Through the points in this stretchout line draw the usual measuring lines, as indicated by the small figures. By means of the dividers set off from O3 A3, on lines of similar numbers, the length of lines in O A D of plan. Lines traced through the points thus obtained, as shown by E3 A3 D3, will complete the pattern of No. 3. The pattern of No. 4 can be obtained in the same manner as was No 2, or No. 3, as may be found most convenient. Adapting the latter method, lay out on P4 A4 in Fig. 3 a stretchout of profile No. 4, through the points in which draw the usual measuring lines, as indicated by the small figures By means of the dividers, set off on either side of P4 A4 the length of lines of similar number on either side of A P of plan. Lines traced through the points thus obtained, as shown by A4 E4 F4, will give the desired pattern of No. 4.

A Sheet-Metal Fountain.

From PHOTOGRAPHER —There are few workers in sheet metal that have any idea into what curious shapes the various sheet metals can be worked. There are at present so many branches of the business that those who follow a particular line are liable to overlook the kinds of work that are being done by others. Such were my ideas when passing the general jobbing shop of Phil. Kempter, 32 North State street, Chicago. In Fig. 1 is shown a general view of the fountain, as it might be called, taken from a photograph. The fountain, which is mainly constructed of gavanized iron, is placed in the front window, and is as attractive a sign as one could desire. Referring to Fig. 2, which is a plan of the article, D C E F is the base of the fountain, which part is shown in plan, Fig. 3, in which K K K K K represents a miniature lake, over which a bridge is placed. There is likewise a



A Sheet-Metal Fountain.—Fig. 1.—*General View of Fountain, taken from a Photograph.*

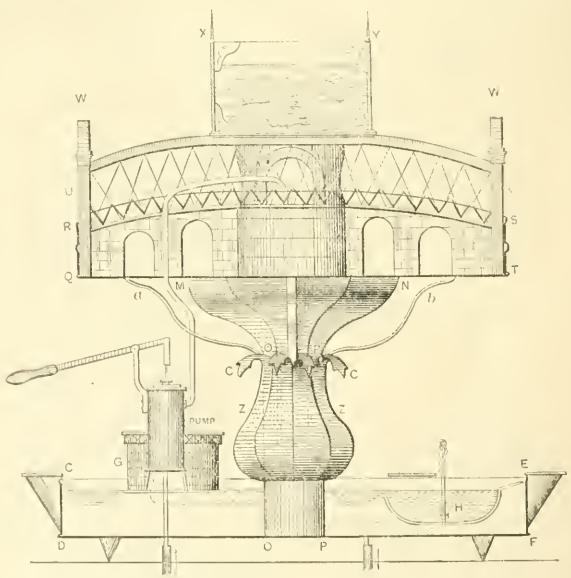


Fig. 2.—*Elevation of Fountain.*

fountain, which is shown in the elevation at G. At the right of the plan is a basin fountain that is shown in elevation by H. The location of the pavilion shown in Fig. 1 is indicated in the plan, Fig. 3, by J. In the elevation, Q R S T is similar to D C E F, which is connected to the base by M N O P and *o p*, O P *o p* being a continuation of M N O P to give strength to the structure. R U V S, Fig. 2, is a railroad bridge, through which a train of cars is seen to be passing. (See Fig. 1.) At W W are two eagles that proudly perch upon the arches. X Y is an aquarium, which has a number of alive and lively fish in the water therein contained. The location of the pump is shown, and from this a pipe is taken, as indicated by the dotted line, so water can be pumped into the reservoir M N O P, when required to supply the two small fountains at G and H. These pipes are furnished with stop cocks, so the supply of water can be regulated at will. The pipe for supplying the reservoir M N O P can be changed so the water can be pumped into the fish pond Q R S T. As the water passes out of the jets at G and H, it flows over into the lake, shown in plan, and

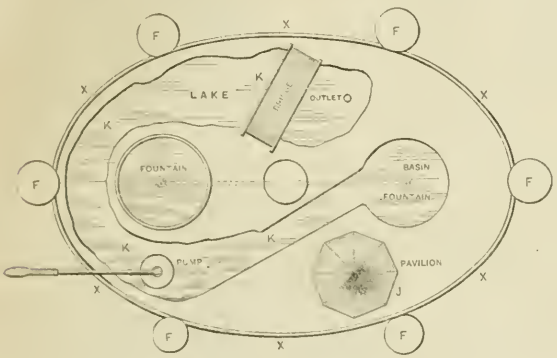

Fig. 3.—Plan of Fountain.

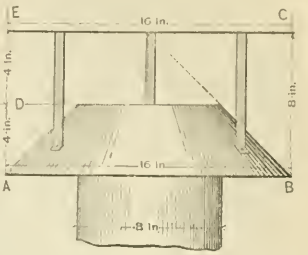
follows the course indicated by the arrows and out at the outlet near the bridge. At *a* and *b* are shown two of the 1½ x ¼ inch iron braces that are used as a support to the fish pond. On general principles, it can be stated that the bridge is intended to represent one that turns on its center, and below is the stone work, as shown in Fig. 2. The arches in the supposed stone work allow the fish or other animals to pass from one side of the pond to the other. About this pond are placed six supports for flower pots (X X X X X X in plan), while about the base are placed an equal number of similar supports, as shown by F F F F F F in plan. The earth or banks of the lake is made from sheet zinc, which, pounded into irregular shapes and painted green, answers the purpose for which it is intended in a very able manner. All of the fountain, except ing the two eagles over the arches and the aquarium, was made by Mr. Kempter, who also designed the structure. As the plan and elevation are drawn nearly to the scale of 1 inch to the foot, the reader will have little difficulty in determining the size of any of the parts or in making a similar fountain of any desired size.

Emerson Ventilator.

From H. C., *Elizabeth, N. J.*—I would like to see diagrams and measurements of an Emerson ventilator published in *The Metal Worker*. There is a difference of opinion among tinners regarding shape and dimensions.

Answer.—In Fig. 1 is presented a side view of an Emerson ventilator that is supposed to be drawn after the original design. These tops are made in a variety of ways, as most tinners have their own ideas on the subject, and make tops unlike the Emerson. If the top was to be made for an 8-inch pipe, from A to B would be 16 inches, or twice the size of pipe. From B to C would be 8 inches, or same distance as diameter of pipe. From A to D and D to E are each 4 inches. The top E C has the same diameter as A B, which is 16 inches. In Fig. 2 is presented a sectional view of top, showing method of construction. The disk G has its inner edge turned for greater strength, and rests on the bead of pipe F. The outer edge of H is turned onto G, when the top of pipe at J is turned over, thus binding the parts together without the use of rivets or solder. When putting the top together, the bead F should be such a distance from the end of pipe that some pressure will be required to bring the pipe through at J, so as to spring the disk G, as shown. The top piece M, when not made of heavy iron, should have the edge strengthened by wiring, and can be fastened to H by riveting on pieces of band iron, as shown at K, or by running rods through, which are held in position by nuts, as at O, or by riveting. When rods are used for holding the parts together, tubes, N, can be soldered about the rods L to prevent water from entering the top, where the rods pass through. When pieces of band iron similar to K are used for securing the top M, the irons should be riveted at H before the parts are put together.

The trip of W. R. Walkley, New York manager of the Peck, Stow & Wilcox Company, and A. R. Treadway, vice president of the same corporation, in charge of the Cleveland factory, to Havana, Cuba, as alluded to recently in our columns, has been accomplished. They left New York, March 15, on the steamer "City of Washington," of the Ward line, and returned by the same boat, encountering a rough passage both ways, arriving here March 28. Among their experiences was a call at a representative Hardware store, where they were hospitably invited to partake of breakfast. It appears to be quite a universal custom for employers in almost all branches of trade to board their employees on the premises, rooms included. The majority of merchants and clerks are said to be Spaniards, and being away from home and without family ties, this custom has obtained. Business is commenced about 6 o'clock in the morning, breakfast being served at 10 a m. This meal, which was a fair sample, consisted of five courses, including wines, mainly claret and sour wine. The repast is described as having been excellent. The host referred to his wine bill per annum as averaging about $3000, 30 bottles being served at that meal. Dinner occurs about 6 p.m.



Emerson Ventilator.—Fig. 1.—Side View.

Among the mementoes of the trip are a few fine cigars, for special acquaintances who call early.

America's foreign trade, though unsatisfactory in results, bears a very favorable comparison with that of Great Britain. In the aggregate British imports and exports combined were 13 5 per cent. smaller in February than in the same month last year, while American imports and exports combined were but 10.8 per cent. smaller than in the same month last year. But this is not all. While the British imports were unusually small the decrease was largely in the necessary materials of great manufactures. On the other hand, the

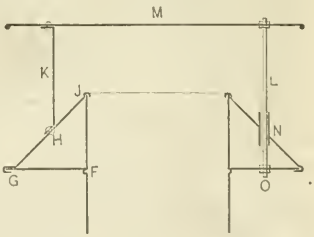


Fig. 2.—Section through Ventilator.

exports from the United States, though very much smaller than for the same month last year, were yet about as large as was usual in that month a few years ago.

Up to the latest advices four large bulk oil tank steamers had passed through the Suez Canal from the Batoum and Baku regions, and this trade is now supposed to be established. The demand for petroleum in the East has gradually assumed important dimensions, the annual consumption, it is said, amounting to 35,000,000 cases, or thereabouts, valued at some $35,000,000, with a steadily increasing demand. The chief part of this large supply was brought from America mainly by sailing vessels by way of the Cape.

Two solid men of iron, ex-Mayor Hewitt and Andrew Carnegie, addressed the General Society of Mechanics and Tradesmen at Masonic Temple, Newark, last week, and gave much good advice.

WORLD'S FAIR NOTES.

Hurrying the Work of Installation.

Only a month remains until the formal opening of the exposition. There is bedlam in the buildings. They roar with the mighty exertions of the workmen. The chaotic condition of the grounds is nothing when compared to the jumble of exhibits, the hurry and skurry of mechanics, the coughing and wheezing of engines and the heaps upon heaps of wood and metal to be seen and heard in the immense structures. There is no time to lose and contractors are pressing their men as captains urge their companies to carry a desperate point.

There is nothing humorous about the work. It is grim and killing. There are a thousand pavilions to be built and a hundred more to be finished before the big doors swing open to the world. Meantime trains burdened with foreign and domestic exhibits are rolling into the park from all points in the country. Huge steam cranes snort and hiss at the entrances. Even electricity is used to facilitate the handling of the ponderous exhibits of machinery. The roar is loudest in Manufactures Building, Machinery Hall, and in the great white structure where the products of the mines and their method of crushing are to be seen. The interior of the great Manufactures Building in these days of turmoil looks like the pictures of the construction of the Tower of Babel. The rumble of trucks over the floor, the roar of the carpenters of 20 nations and the cries of the men make a deafening din.

If there is to be one uncompleted building in the park, so far as pavilions and booths are concerned, it will be the mighty Manufactures, and it is here that the most frantic endeavor is being made to stretch a minute into an hour. The little Japs, working like squirrels in their queer blouses and ostrich-toed stockings, have made more progress than the rest of the exhibitors, although Germany, with an exhibit which will astound the world, is toiling with might and main to prepare its pavilion for the reception of its display. England's exhibit is pouring into the building. It is coming on every train. And side by side with it are the big boxes and crates from Austria and Belgium.

There is an immense amount of work to be done in the Manufactures Building, but the force of workmen is being increased each day. It is scarcely probable that all the exhibits consigned to the big structure will be installed by May 1, but the building, like the gates of the fair, will be opened on time and there will be enough to be seen there even on that day to bewilder and charm the eye. There is also a wild uproar in Machinery Hall. The exhibits here are for the most part so ponderous and so unwieldy that the work of placing them in their proper places is necessarily slow. Like the Manufactures Building, the display in Machinery Hall will scarcely be completed by the opening day. Electricity is being used to hoist, transfer and lower the huge engines and machines, and an army of brawny men, many of them in the strange garb of foreign countries, are hauling and tugging away at steam chests, piston rods and wheels of amazing diameter. The German exhibit in this building, as is the case in other departments, is nearly ready for the band to play. Looking down upon the piles of iron and steel and brass from the east gallery it would seem to be an impossibility to set the wheels agoing before July 1; but men work wonders at the fair these days. An immense structure has been erected in four days. Even 500 carloads of exhibits can be handled in a single day. Considering all this, and the fact that men in Machinery Hall are not only working like demons upon the floor, but are riveting and welding things while suspended in the air, there are reasons to accept the confident assertions of contractors that the displays will be in good shape on the opening day.

Work is more advanced in the Mines Building, where the floor is strewn with exhibits and splashed with the pavilions of countries famed for their minerals. Agricutural Hall is also in good trim now that the glass broken by the heavy snows of the winter is being replaced. For a time exhibitors in this building were bothered by water falling from the roof upon the space assigned for their displays. Since the leaks were stopped work has progressed steadily, until the main floor, as well as the balcony, is thickly dotted with pavilions, many of them of the most interesting and unique character.

There has never been much concern about the Electricity and Transportation buildings. Electricians have a way of doing their work with incredible speed, and it may be confidently predicted that their display, which will be the most wonderful of its character ever seen in the world, will be a "blazing and a singing and whirring" on schedule time.

The same is also true of the Transportation Building. Most of the exhibits for this department roll on wheels, and they are rolling in all the time. The main floor is already filling up with locomotives and specially constructed trains, and upstairs men are pushing vehicles and odoriferous canoes into place. Over at the Fisheries Building, where the guards have had nothing to do for months but press their faces against the window glass and watch the skaters on the ponds, there are signs of activity. Last week the first consignment of fish was received at the building, and from this time until May 1 the slate-colored cars of the United States Fish Commission will help fill the tanks in the building with fish.

The State and Foreign buildings will be finished by May 1. Many of them are now ready for occupancy and the rest are so well under way that there can be no question as to their completion by the specified time.

Nearly 10,000 men are now at work under the direction of the construction department. By far the larger proportion of them are on the pay rolls of contractors under bond to increase their working forces any time they may be ordered to do it. Foreign countries have a thousand or more men in the park, some of them putting the finishing touches on their buildings and others unpacking and setting up exhibits.

The Manufactures' Roof.

The reports that have been published in Chicago papers of late concerning the condition of the roof of the big Manufactures Building have greatly displeased Director-General Davis and Chief Allison. Last week Chief Engineer Shankland gave out the following as an official report of the condition of the roof:

"When the snowslides of last month broke large sections of the glass in the roof orders were at once placed for a large supply of the glass required to make the necessary repairs. There has been great difficulty in getting this glass, as it had to be made, and it is only within a day or two that it has begun to arrive. The places in the roof where the glass was broken have, of course, been leaking, owing to the numerous rains and snows of the past month. There is no such thing, however, as a general inundation of the whole Manufactures Building, and any complaints that may have been made by exhibitors were probably made by those whose floor space is located under the broken space in the roof. With two or three days of fair weather now, the roof will be repaired in such manner as will stop all leaks and all complaints."

America's Adam and Eve.

Two figures cut from marble, to represent the typical American male and female forms, will make one of the most interesting features of the ethnological exhibit. They will be installed by Professor Putnam in his laboratory in the Anthropological Building.

These figures are now being completed by Harry Kitson and Miss Theo. Ruggles, both well-known sculptors and both of Boston. Theirs is the first attempt ever made to reproduce in marble the typical form of a whole people. The idea originated with Dr. D. A. Sargent, Director of the Harvard Gymnasium, who has given much time and attention to the matter, furnishing for the use of the sculptors most of the measurements. The figures are really the result of measurements carefully taken by the most approved anthropological methods of no less than 10,000 different persons, nearly all of them in bloom of youth, that is, between 18 and 25 years of age, and the great majority of them college students, 5000 Harvard undergraduates alone having been measured for the male statue. A number of measurements of students of other colleges and a few of professional athletes have been used.

There are a little less than 5000 measurements of ladies, and they are from Harvard Annex, Smith, Vassar, Wellesley and other female institutions of learning.

Ever since 1880 these measurements of Harvard men have been pilling up in the archives of the gymnasium of that institution of learning. Sixty five different measurements were taken of each individual before he was considered measured. These sixty-five measurements have been taken of every one of the 10,000 people represented in the two figures.

The measurements include the girth of head, neck, trunk, arms and legs, each in a number of different places, the length of the body and limbs, both standing and sitting, and a part of other dimensions too numerous to mention. Then the sixty-five measurements of the 10,000 people are classified and the mean obtained of each one of the sixty five. A mean, be it noted, is not at all the same as an average. The mean is, instead, the instance that is found most frequently; for instance, if more of the 5000 men are just 68 inches tall than there are of any other hight, 68 inches, the mean, is taken. By this method of calculation the extremes do not count, and the true normal type is unaffected by the freaks and eccentricities in which even mother nature at times indulges. Scarcely an individual has filled the measurements of the type in more particulars, and a great multitude, of course, have not a single one of the measurements of the typical figure.

The faces are taken from composite photographs. Some 300 faces of young men will be represented in the face of the male figure, and about as large a number in that of the female. The female face is that of a composite representing a number of separate composites from the different female colleges already enumerated. The face of the male figure, which is beardless, is a composite of Harvard men, reinforced by composites from Amherst, Bowdoin and other colleges.

The figures will be completed early next month and will be installed by Professor Putnam before the opening, May 1. Speaking of them yesterday, Professor Putnam said: "This work has been carefully done by Dr. Sargent. His measurements represent a vast amount of labor. The figures will interest the general public and will prove of great value to those who make a study of the physical development of man. This is, I think, the only method that could have been pursued to secure the

real proportions of a typical American Adam and Eve. Replicas of the figures in metal will be furnished all museums that may wish to possess them."

The Fisheries Exhibit.

Live fish are now being placed in the aquaria of the Fisheries Building. These aquaria are ten in number, and occupy the east pavilion of the building. They each have a capacity of from 7000 to 27,000 gallons, and, combined, form the greatest aquaria in the United States.

In the center of the pavilion will be a pool 30 feet in diameter. Workmen are putting the finishing touches upon this feature of the general exhibit, arranging the rockery and placing the aquatic and semi-aquatic plants. The water will be filtered so that it will be as clear as crystal. From crevices in the rocks jets will spray toward the center. And as in this pool are to be exhibited the goldfish, golden ides, golden tench, and the many colored fish from Japan, it will have the appearance of an immense aquatic kaleidoscope.

Surrounding the pool will be the aquaria proper. The tanks are so arranged that the glass portions come within range of vision at about three feet from the floor. They are in two groups; one for salt water specimens, the other for the denizens of the lakes and rivers. Each tank will contain rocks built up in ornamental designs, and specimens of plants indigenous to that section of the world represented by the fish. In this manner will be illustrated as far as possible the bottoms of the principal American rivers.

One of the largest tanks is that in which will be the exhibit from the Mississippi river. It is 70 feet long, 12 feet wide and 9 feet high. This aquarium is to contain the largest specimens of fresh water fish in the building. Specimens of catfish, shorel fish and sturgeons weighing more than 200 pounds each have been captured, and as soon as all is in readiness for their reception will be forwarded to Jackson Park. This tank occupies the eastern half of the first series of aquaria immediately surrounding the pool.

On the west side of the pool will be several large tanks, to correspond with the Mississippi aquarium, in which will be exhibited the sea fish. Then comes an aisle, and in the outside circle around the walls of the building will be rows of smaller aquariums.

Light from the outside windows shines directly through the aquaria, so that visitors in the aisles will have no difficulty in viewing the fish. The system is provided with pumps which keep the water constantly fresh. The salt water will also be made as nearly clear as possible. It will be brought from the Atlantic in tank cars, each having a capacity of 30,000 gallons. A special car has been constructed to transport the live exhibit.

This portion of the fish and fisheries exhibit is under the United States Government Fish Commission. Professor Forbes of the Illinois University at Champaign is in charge. Every noted species of curious, edible and commercial fish of the United States will be exhibited some time during the season. The Fish Commission will have in the Government Building a large display of mounted specimens, fishing apparatus and mounted aquatic plants by which certain fish find maintenance. There will also be a display of the hatcheries of the commission, showing the methods of propagation.

The inanimate collection now in the building contains life-like reproductions of many curious ocean fish, several of which are very large. In this section will also be a collection of fishing boats in use off the Atlantic coast.

Perhaps no building at the park presents in its exterior decorations a more complete story of what will be its contents than the Fish and Fisheries Building. Every column, every cornice and every capital is covered with ornaments that are life-like reproductions of familiar fish, reptiles and creatures that "inhabit the waters under the earth." The friezes over the entrance doors show groups of frogs that are evidently enjoying life as only plaster frogs can do. One pillar of the south porch is decorated with sea crabs in *bas relief;* another is ornamented with scores of plaster flounders, while others glorify lizards, terrapin and lobsters.

The Department of Fish and Fisheries, to which the Government Fish Commission exhibit is a valuable adjunct, will be divided into three classes. In the main building will be exhibited fish products and commercial elements of the fishing industry. In the east wing will be the display of live fish. The western pavilion will be devoted to collections of angling apparatus of all kinds. This exhibit will be competitive, and will include all kinds of fishing tackle and appliances in use in this and foreign countries. In fact this portion of the building will be a fisher's paradise. In it the lovers of the gentle art may assemble to swap yarns and examine the latest wrinkles intended to deceive the wary trout.

The display is intended to embody the perfect articles in use at the present day, and to illustrate for contrast as many of the ancient and barbarous methods of catching fish as possible.

Models of Hell Gate.

To New Yorkers, and in fact to all who have visited the great metropolis of the Atlantic seaboard, one of the most interesting exhibits at the fair will be a series of models illustrating the improvements in the waters in the vicinity of that city. These models are unique in design, and have been in process of construction for nearly two years under the superintendence of Lieut. Col. George L Gillespie, who is in charge of the river and harbor improvements in New York and New Jersey.

Government authorities at Washington, recognizing the general interest in civil engineering, have given the exhibits the place of honor in the Government Building. The visitor entering the Building from the western entrance facing the lagoon will see first a model of Sandy Hook In the immediate vicinity of the Sandy Hook plan will be grouped all of the models prepared by Lieutenant-Colonel Gillespie's force now at work in New York City.

With these in the northwest corner of the building will be displayed representations of work done at the mouth of the Mississippi River; of the harbor at Key West, Fla.; of the iron pier at Lewes, Del.; of the Delaware breakwater; of the pulsometer at League Island and the stone scow at the Delaware breakwater. To afford visitors an opportunity to see these models wide aisles have been laid out surrounding them.

Orders were first issued from Washington August 8, 1891, for the construction of the models, and work has been continuous from that day to the present time. There are in all eight exhibits illustrating the work now being carried on in New York harbor. Five models show the work done by the late General John Newton in removing the Hell Gate obstructions.

One shows a section of rocks near Hallett's Point as it appeared before the first explosion in the fall of 1876, when General Newton's little daughter pushed the button and caused the mass of rocks and water to fly skyward. By turning a crank the surface is made to rise, revealing underneath it the galleries made by blasters and the headings, the short headings, with holes plugged with dynamite cartridges, the coffer dam, and the whole work as it appeared when all was ready for the blast. The topography is reproduced according to the scale of 1 inch to a mile.

Another model represents a general view of Hell Gate as it appeared before 1869, when operations were begun by the Government.

They Have Fallen by the Wayside.

One more projected enterprise on Midway Plaisance has fallen down. It was the concession granted to the Barre Sliding Railway for running trains the length of the Plaisance. The company was notified by the Council of Administration that, having failed to fulfill the terms of its contract, it would have to relinquish its place. The Barre Sliding Railway was a unique project and one that promised to distance railroad trains in the lightning swiftness of its speed. Its cars were to slide over a thin surface of water which coated the rails. These were the usual distance apart, and an elevated structure a mile long on which were the tracks had been practically completed when the company found itself unable to go ahead. The cars were to be propelled by jets of water, and a speed of 60 miles an hour was said to be merely an ordinary rate. The railway was exhibited at the last Paris Exhibition and was reputed to have been one of its wonders. The Exposition Company will buy the elevated tracks from the concessionaires, and the road will probably be used as an electric line. It will be easy to conduct it with the electric cars used by the Intramural Railway in Jackson Park. It is a mile from one end of the Plaisance to the other, and it will be necessary to afford transportation to visitors along that strip of ground.

Another enterprise which seems to have come to naught is the projected lofty tower, known as the Johnstone Tower, on the Plaisance between the Illinois Central tracks and Stony Island avenue. This tower was to be built of steel over 500 feet high, with a circular railway winding nine times around before reaching the summit. At night the tower was to have been illuminated with 10,000 incandescent lamps, which would have made it appear like a shaft of light. The Tower Company were late in beginning their work and it seemed impossible for them to build a structure such as was designed by May 1. Barring a few hundred piles now lying along on the site there are no other evidences visible of progress. A lonely pile driver is started up two or three times a week, and after pounding a few piles takes a rest for another day or so. The Tower Company have until April 1 to furnish evidence that the structure will be built. None of the officials, however, expect to see the project rise any higher than the surface of the ground.

Montana's Silver Statue Well Cast.

The silver statue of Montana's "Justice," for which Ada Rehan, the actress, was the model, has been successfully cast and is now an assured fact. The casting was done on the 18th inst. At ten o'clock on the following morning a number of those interested in the statue were on hand in the foundry of the American Bronze Company at Grand Crossing, near Chicago, where the silver had been cast into the mold, to see what was the result of the undertaking. Julius Berchern, who had charge of the work, had his assistants remove the molds. He was in a state of great trepidation and had been ever since the molten silver was poured in. He had scarcely rested during the night and could hardly retain his patience for the 22 hours necessary to allow the statue to cool. When the mold was removed it was found that the work of the founder was as near perfection as could be. It was expected that the cooling of the white metal would

leave air-holes, cracks, and flaws here or there on the statue, but not one was noticeable. The achievement is noteworthy, as the statue is of the full size of the human figure and nearly a ton of silver was used, a metal with which founders have had little or no experience in casting in large masses.

Exhibits from Ontario.

The mineral exhibit of Ontario, Canada, will consist of 1600 samples of ore from all parts of the Province, and five carloads of it were shipped from Toronto last week and one carload from the Sudbury district. This latter car contains nickel alone, and there is one solid chunk of pure or refined nickel which weighs 4600 pounds. The mineral displays altogether will exceed 100 tons in weight. One of the most artistic as well as attractive and unique displays in the Ontario court will be entirely prepared by Indians of the reserve in the counties of Brant and Haldeman. This will consist of a monument or trophy entirely made of pieces of timber comprising 13 varieties, and all of which have been prepared and fitted without the use of saw or other utensils except a jackknife. Yet the timbers are squared and molded with a perfectness that could not be excelled by the most elaborate machinery, and the pieces are polished by the hands of the Indians. Surmounting the timbers forming the base of the trophy will be five wooden columns elaborately decorated by carvings of native birds and animals, all being done with a jackknife. On the top of each column will be a small belfry, and above all a large belfry. The entire work is the result of six years of labor of two or three educated Indians. The sides of the base will be richly inlaid with various specimens of wood.

In the mineral section some delay has occurred by the necessity of strengthening the floor. One specimen of rich iron ore will weigh over 10 tons. In every department these exhibits of Ontario will be complete, and for their arrangement and care a force of more than 60 men will be continuously employed during the Fair.

Must Have Credentials.

Considerable annoyance has recently been caused in the various departments by persons claiming to represent foreign and domestic exhibitors and State commissions. In many cases the claimants have caused confusion in assigning space, and it has become difficult for the authorities to determine exactly whom they were dealing with. In order to obviate this difficulty hereafter the Director General issued the following general order:

To all Department Chiefs.—No person will be recognized, or permitted to act as agent in the World's Columbian Exposition for an exhibitor, or for a foreign or State commission until he has filed satisfactory written evidence of his authority.

In the case of agents for domestic exhibitors, satisfactory evidence will be a formal power of attorney, which must be filed with the chief of department to which the exhibits pertain.

In the case of agents for foreign exhibitors, satisfactory evidence will be the written authority (preferably power of attorney) of the principal, which must be approved by the commissioner-in-chief of the country of which the exhibitor is a subject, and filed in the office of the Director-General.

In the case of agents for foreign and State commissions, the proper evidence will be the written authority of the head of the commission, which must be attested by the secretary of said commission and filed in the office of the Director-General.

GEORGE R. DAVIS,
Director-General.

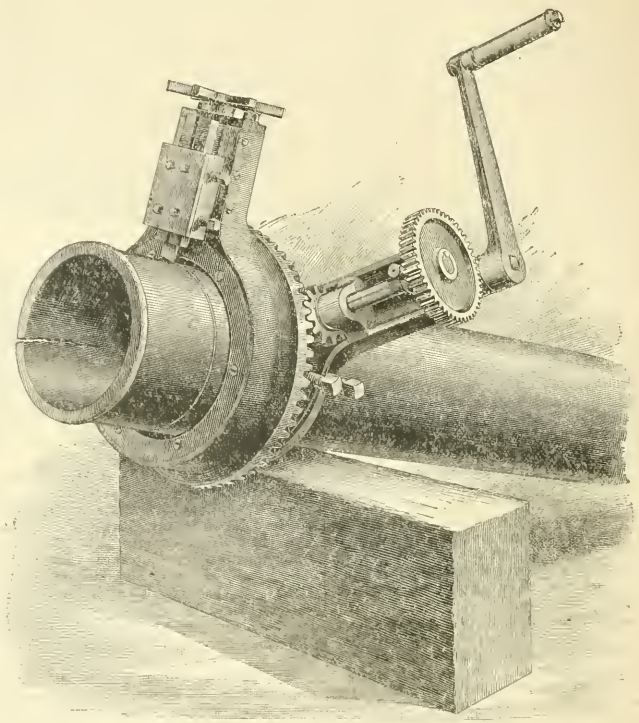
Items.

One of the big pieces of machinery at the fair will be a 1500 horse-power combined engine and dynamo. It is to be exhibited by the General Electric Company, by whom it has been built at Schenectady, N. Y.

The boiler plant at Jackson Park is now being heated by oil. Two batteries of eight boilers have been fired for seven days with this fuel with satisfactory results. No perceptible odor is emitted and the smoke nuisance is avoided.

The claim is made that the largest wood split pulley in the world has just been shipped from Columbus, Ind. It is a part of the Reeves Pulley Company's exhibit which will be made at the World's Fair. It required two and one half kegs of nails and 100 pounds of glue to unite the 2800 pieces of wood of which it is composed. The pulley is 18 feet in diameter and has a face surface of 4 feet.

A pair of light chain tongs is all that is necessary to hold the pipe, and on large sizes, where the pipe is heavy, nothing more than chocks are needed. To cut off a cracked pipe the machine is moved along to the point where the crack ceases, and not a foot behind the crack, as has been customary; by so doing the cost of a foot of pipe is saved every time a cracked pipe is cut. It is possible to cut on a bevel by simply slackening the screws on the top side of the frame and setting them up on the bottom side, and as the machine must cut square to its own axis, the required result is obtained. It is claimed that the economy of this machine is represented by the difference between the work of two men not exceeding 40 minutes each and the work of five or six men from 60 to 75 minutes each on 20 inch or 24 inch pipe, with a proportionate amount of saving on all other sizes.



THE FRENCH PIPE-CUTTING MACHINE.

The French Pipe-Cutting Machine.

This machine—which is the invention of D. W. French and is put on the market by Benjamin C. Smith of 52 Cliff street, New York—is intended for cutting pipe from 4 to 48 inches in diameter. The machine is very simple in design, and while light, so as to be easily handled, it possesses sufficient strength to stand severe usage. In using the machine all that is required is to mark the pipe where it is to be cut, slide the machine along to the point designated and set up the screws which hold it in position on the pipe. The machine is operated by means of the crank shown, which can stand in any position desired. One end of the pipe to be cut is raised about 1 foot, so that the rotary head carrying the cutting tool will clear the ground in passing around the pipe.
